A larger printing press shown by the same firm is driven by steam. This is intended for printing in three colours, numbering, perforating, and cutting. In this machine the paper is continuous, and, in the one shown at the Exhibition, is 9in. wide. If numbering is not required, it can be printed in four colours, of which all can be on the same side, or three on one side and one on the other. The paper is on a roll near the bottom of the machine, and the strip is brought over guide rolls in such a manner that whilst one press in the lower part is printing the first colour, the second and third are being done on the continuation of the strip by other presses above. It depends on the arrangement of the paper on the guide rolls whether the first impression is made on the front or back. The second and third, also the fourth or numbering, must be on the front. The paper when required is then perforated longitudinally, and either cut off to any desired length or perforated transversely and rolled on a drum at the opposite end of the machine.

The exhibitors also show a machine which they have just brought out for cutting paper into strips for receiving telegraph messages on a Morse instrument. It takes a roll of paper 14in. wide, out of which forty strips or "tapes" are cut by circular knives. These are all coiled on the same roll, until the required lengths have been cut; but when removed from the machine they fall apart. Thus the effect is the same as if the solid roll had been cut through, though in that case the strips would naturally not be so neatly or accurately cut as by the present method. A few machines for ticket-dating, &c., also form part of the exhibit.

Messrs. Preusse and Co., of Leipzig, show a number of different descriptions of bookbinding machines at work, and also the various machines necessary for the manufacture of wire-sewn cardboard boxes. Commencing with the smallest size for stitching pamphlets, they go on to the double pamphlet stitcher, with two adjustable heads, which can be set from 3in. to 6in. apart, and then to the regular octavo and quarto bookbinders, stitching on cloth or tapes, with four or more heads. In one machine shown the work is continuous. The sheets to be sewn are placed across an oscillating ledge, which takes them to the needles. Books of any thickness can be sewn, and it is not necessary to cut each away directly it is finished. A wooden distance piece about ¾in. thick is inserted, and then the stitching of the next book is commenced. A carrier at the back moves the finished books to a slide, so that they can be cut apart when desired, and there is no occasion to stop the machine until the supply of cloth or wire is exhausted.

The largest make of machine is called the "Imperial." It has nine heads, and is intended for account books. It will take books up to 26in. in height by 6in. thick. All these machines use wire, but Messrs. Preusse also show a thread sewing machine, intended for *editions de luxe* and other high-class work, for which cotton is considered to be preferable. It will take any size of book up to 13½in. by 10¼in., will make from one to five band stitches on the backs, and works continuously.

Instead of pasting the corners of boxes together with strips of cloth, the exhibitors maintain that it is cheaper, as well as stronger, to stitch them with wire, and they have several sizes of machines for this purpose, according to the thickness of the cardboard and the depth of the box. In all of them there is a continuous roll of wire, usually flat; and the machine cuts this into lengths, forces the staples in from the outside, and then clinches them and drives the points in from the inside. Another variety of the machine, which may be used for circular or any shaped boxes, as well as for pamphlets, sews flat along the side of the box. It is also used for strengthening the corners by stitching wooden strips into them. A machine which attains the same object of stiffening cardboard boxes, though in a different manner, is the tin-plate cornering machine. In this, ornamental indented strips of coloured tin-plate are fastened by pressure along the edges of boxes, which are thus stiffened considerably without any great addition to their weight.

They also exhibit a series of machines for the manufacture of folding and parcel's-post boxes. Each set consists of three machines, one to bend and cut; another to stamp out, or "blank;" and a third to sew. These are all made in various sizes: in the first, the largest machine will take cardboard up to 4ft. 9in. wide, of which it will cut 10in., and crease the remainder ready for folding. The blanker cuts out the flaps and holes, and is so constructed that the waste produced by its operation is automatically removed whilst working. Finally, the box is stitched flat along the sides with round wire. For small-sized boxes a special form of blanking press is used, which will also groove, so that a bender is not required.

Finally, Messrs. Preusse show two descriptions of folding machines, one for books and the other for newspapers. Being furnished with self-acting sheet straighteners and angle-guides, they fold the sheet into 4, 8, 16 or 32 as neatly as can be done by hand, and deliver the folded sheets into a till at the bottom. All that the attendant has to do is to place the sheet on the machine. The newspaper folder first folds the paper in four or eight, and then doubles it twice in the same direction, to make it in a suitable form for posting.

Similar newspaper folding machines are exhibited by Messrs. Molitor and Co., of Heidelberg. There is a little difference in the construction, but they work equally well. They also exhibit the Lightning Press, intended chiefly for wrappers, of which it can print 5000 per hour.

Very little German brewery plant is shown. The principal exhibitor in this branch is Mr. P. Kyll, of Cologne, who exhibits an apparatus intended to supersede the ordinary cooling-back, or the refrigerating machinery which is usually preferred by German brewers to the open back. In this apparatus, an air pump, which is cooled by water, forces air through a double filter, containing first permanganate of potash, and afterwards, cotton wool soaked in salicylic acid. This air, thus disinfected and cooled, is forced into a long oval covered vessel containing wort. In this there is an outlet at the end for the escape of steam, and water sprays over the whole of the exterior surface. The wort is allowed to remain from four to eight hours in this receptacle, and it is found that 500 gallons of cooling water at 59 deg. Fah. will lower the temperature of 400 gallons of wort from 212 deg. Fah. to 122 deg. Fah.

Another exhibit by the same firm is a steam boiling pan for maize, sweet potatoes, &c., intended for distilling. It is heated by steam at a pressure of 45 lb., from a separate boiler, which also supplies steam to an engine; and the peculiarity of the arrangement is that this engine is carried by the under-frame of the pan, whilst three pumps for water, wort, and residue are on the opposite side, so that, with the exception of the steam supply, the whole apparatus is carried on the same frame.

Next to the gas and petroleum engines, and the electric motors, the visitor will probably be struck by the number of milling machines. Those exhibited by Messrs. Smith and Coventry have already been described, and in a subsequent letter I shall have to mention machines of French and Belgian make. Amongst German tool makers a large stock of milling machines is shown by Messrs. Reinecker and Co., of Chemnitz. These are horizontal and vertical, with the usual automatic movements, but a more interesting part of the exhibit consists of tools for forming the cutters of these machines, as well as for making taps, rimers, &c. Amongst these I observed a special lathe for making spiral milling-cutters, the section across the cutters being in the shape of a ratchet-wheel. In this the cut gradually deepens, and when the tool gets to the end of the cut, it is lifted out by a spring, and comes into position for the top of the next tooth. Another lathe turns the piece which is being made alternately forward and backward, with a slow forward movement that may be varied, and a quick return. Besides tools with cutters, there are several with emery wheels, chiefly used for finishing. But the chief novelty shown by Messrs. Reinecker is a measuring machine. The exhibitors claim that this instrument will, in comparatively unskilled hands, show to the naked eye differences of 1-10,000th of a millimetre, or 1-250,000th part of an inch. Gauges of guaranteed accuracy, which have been tested at 57 deg. Fah., are supplied with the machine. These gauges vary from $\frac{3}{16}$in. up to 4in., and the measuring consists in comparing the length of the object to be tested with one of these standard gauges, and noting the difference. The apparatus resembles a small lathe, but without driving gear or tool holder. A carriage on the bed-plate supports the piece to be tested. The back centre protrudes from a metal disc, which presses against a diaphragm, whilst the front centre can be moved forward by turning with a thumb screw a large brass wheel, divided on the rim into thousandths, and fitted with a vernier, so that it will register one ten-thousandth of a revolution. This diaphragm forms the front of a vessel containing coloured spirit, from the top of which rises a fine glass tube. The standard piece is first placed in the machine, and the wheel turned till the disc, pressing against the diaphragm, causes the spirit to rise in the tube. The height to which this rises is noticed, and the position of the wheel is read off on the scale. The piece to be tested is then inserted, the wheel turned till the spirit rises to the same level as before, and the scale on the wheel again noted. The apparatus is so sensitive that if the hand be placed for a few seconds on the object which is being tested, it causes the spirit to rise in the tube. A large collection of taps, wrenches, dies, spiral drills, gauges, and milling cutters form part of this exhibit.

Mr. F. Flinsch, of Offenbach, exhibits a series of machines for the preparation of tobacco. The first, styled the "torrefactor," is a revolving iron drum, into which the tobacco is placed, and a current of hot air passed through. There is also a small fireplace underneath. As soon as the tobacco has been properly dried it is passed to a second revolving drum, lined with sieves. Cold air is forced through this, and at the same time the dust falls into the space between the sieves and the outer casing. It is next passed through a cutter, an apparatus similar to a guillotine for paper, but with rollers to press it forwards. A fourth machine makes up the tobacco into packets. In this a pillar with four arms stands in the middle of a table. Under each arm is a receptacle, the breadth and width of a packet, and these four boxes revolve round the central pillar. The first arm presses the tobacco into the packet, the second folds the paper and closes, the third compresses a second time, whilst the fourth seals the packet, which is automatically ejected by a piston under the box. The size of the packets can be regulated as desired, and the machine will turn out 600 per hour.

A similar set of appliances is exhibited by Mr. W. Quester, of Cologne, who guarantees his cutting machine to shred the tobacco to the fineness of $\frac{1}{175}$ of an inch. A peculiarity of this machine is the automatic arrangement for preventing choking: when the feed is too quick, the mouthpiece, which is movable, lifts, and cuts off the supply. Mr. Quester also shows a press for tobacco stalks, which renders them as fine as the thinnest leaves.

Though electric motors for machinery can no longer be considered as novelties, the manner in which they are applied by the Deutsche Electrizitäts Werke, of Aix-la-Chapelle, seems to be new. They show lathes, drilling machines, &c., each with a small motor fitted into a box in its base. Each of these motors will exert about one-half-horse power, as they give 4 amperès and 100 volts. The advantage of a separate motor for each tool in small workshops is obvious, and these are so compactly arranged that the dynamo takes up no extra space.

Messrs. Burberg Brothers, of Mettmann, are exhibiting a disintegrator, which is not shown at work, though it appears to be a serviceable machine. It is 3ft. 5in. diameter by 8in. wide, and has eight beaters. The sides and ends of the casing are lined with narrow strips, set like louvres. Some of these have smooth edges, others are studded with small points, according to the nature of the material to be treated. Messrs. Burberg say that this machine is capable of grinding two tons of wood or bones per hour. A competition between this and some of the disintegrators already described would be interesting.

Another exhibit which looks good, but cannot be seen at work, is a steam jet cupola, exhibited by Mr. F. A. Herbertz, of Cologne. Whether the use of the steam jet in furnaces is advantageous is a matter of opinion, but the arrangement of the hearth on wheels, so that it can be easily withdrawn for repairs, would be very useful both for copper matte and for lead. There are several other exhibits which, like this furnace, are put up and then left, without anyone to describe their advantages, and which, for this reason, may possibly not attract the attention they deserve; but I think that the machines to which I have called your attention this week and last are sufficient to show that the problem of rapid and economical production is being seriously considered by German manufacturers. I propose next week to describe some Belgian exhibits, which are not less interesting than the German.

## THE DESIGN OF MAIL STEAMERS, WITH SPECIAL REFERENCE TO THEIR USE FOR WAR PURPOSES.*

By Professor J. H. BILES, M. Inst. Naval Architects.

(*Continued from page* 112.)

IN considering the subdivision of a vessel for war purposes by longitudinal bulkheads, it may be objected that when one side of a ship is damaged by collision or gun-fire, the vessel may receive a very inconvenient and possibly dangerous heel. This may be obviated by placing similar compartments on opposite sides of the ship in communication with each other, either by pipes of large size, or, if the compartments be immediately above the double bottom, by setting off one frame space in the double bottom through which water may flow freely from one side of the ship to the other. This is a simple method of automatically maintaining an upright position in a warship which is liable to penetration near the water-line by gun-fire or other means, as the water which enters one compartment on one side of the ship and tends to cause the heel will find its way freely to the other side and prevent the heel. Naturally more water enters the ship, but it is submitted that it is better to have a little more immersion than an inconvenient and possibly alarming heel. This method of maintaining the upright may be worth adopting from the first in a mail steamer, as far as the lower bunkers are concerned, because it can be simply applied, and is a precaution against excessive heeling in the case of collision; but the provision for its adoption in the case of the further subdivision of compartments above the lower deck in war time would be a more serious matter, as the number of compartments is greater, and the communicating pipes would have to go through the lower bunkers. These pipes might either be put in permanently when the ship is building, or be treated as war-time fittings, which would be removed from the ship after they had been first fitted and placed in store. The part in the double bottom must be fitted when the ship is building. These communicating pipes should have no valves upon them, but should extend from side to side, and should always be open, and, therefore, always ready to serve their intended purpose.

With reference to the main transverse bulkheads of a ship, so much attention has been given to their construction and spacing by the Bulkhead Committee that there is no necessity to take up time with this matter. Ships have been built with bulkheads placed so as to fulfil the condition of being able to float with any two adjoining compartments in communication with the sea, and no large ship which it is intended shall be used for war purposes should be without such subdivision. For war purposes the chances are that, other things being equal, the greater the number of transverse bulkheads the longer will a ship remain afloat under gun fire, provided that the bulkheads are free from openings and strong enough to resist water-pressure. For carrying passengers there is a limit to the smallness of the compartments, especially when there are no openings in the bulkheads. Each compartment so separated from the others must have its own stairway, and the loss of space due to a large number of stairways would become serious. Probably 32ft. to 35ft. is the minimum distance which is permissible between main transverse bulkheads, thus dividing a ship, say, 500ft. long, into fourteen to sixteen compartments.

The question of subdivision for war or mercantile purposes cannot be considered at the present time without dealing with the question of openings in the bulkheads. In a mail steamer it has been demonstrated to be practicable to have bulkheads without doors in all the passenger and cargo compartments, and doors only in the machinery space well above the water-line. The safety and simplicity of such an arrangement is obvious. If a vessel so divided goes into action, or into fleet manœuvres, one considerable cause of anxiety is absent. The vessel, as far as transverse bulkheads is concerned, is always ready for action, and cannot be put in danger by the unauthorised opening of water-tight doors. The disadvantage of such an arrangement for a warship or a mail steamer used for war purposes is, that passage between compartments can only be had above the water-line, and consequently in an exposed position. Those who will have to fight warships can say which is the preferable risk to take. With the unpierced bulkheads the ship is more secure, and in vessels of the cruiser type, amongst which the mail steamer fitted for war purposes must be classed, subdivision is its chief defence. It seems, therefore, desirable to endeavour to retain the bulkheads intact. There are, however, other things to provide for besides openings for men to pass through. Even in those vessels which have bulkheads unpierced for doors, there are pipes passing through below the water-line. The method of pumping and draining the ship usually adopted is to have one or more central stations in the machinery space, from which pipes are led into the different compartments, so as to pump any water from them. These pipes pass through the bottoms of the bulkheads. Any damage to a pipe occurring in a flooded compartment will cause the water to flow through the pipe to the compartment intended to be pumped out by the pipe, and it is quite conceivable that a central station may be damaged when the compartment in which it is is flooded, and all the compartments drained by the pipes connecting with the central station might be soon flooded. This can be obviated by putting a pump in each compartment, and as it is impossible for any pump to cope with a very serious leak, it is only possible to use such pumps for draining a compartment, or for coping with a small leak, such as would be likely to occur from a small injury to an adjacent bulkhead.

In a mail steamer divided into main compartments 32ft. to 35ft. long, it would be quite practicable to have such an arrangement, but in a warship divided more minutely than this, and still further subdivided by horizontal flats, it would be quite impracticable to have such an arrangement for every compartment. One method of carrying this out for the main compartments of the ship is to have at each main transverse bulkhead a small compartment large enough to hold a steam pump. This compartment should be water-tight, and accessible directly from a deck above the water-line by means of a trunk. On the side of the compartment at the bottom there should be a sluice valve, worked from a deck above the water-line. The water in the main compartment could be drained into the pump compartment through the sluice valve, from which it could be discharged by the pump. The steam connection to the pump could pass through the bulkhead above the water-line, so that the main compartment could be efficiently drained, and the bulkheads need have no holes in them below the water-line. The sluice valve and pump suctions would in all ordinary times be accessible from the deck for examination. This is a matter of importance in cargo holds, where pump suctions and sluice valves are usually quite inaccessible.

A method of carrying out this idea, and at the same time assisting the structural strength of a bulkhead, is to make all the bulkheads dividing main compartments double instead of single. The space between the two bulkheads is available for the trunk purpose named above. It can hold the pump, and will serve the further purpose of a well to the double bottom, with the important advantage that if a double-bottomed vessel runs over something which opens to the sea the outer skin beneath the double bottom, the water cannot flow into the vessel's holds through the supposed non-return valves in the tops of the wells, as is the case with the present arrangements, but is confined to the space between the bulkheads, and may rise to any height it can without flooding a compartment. Such a double bulkhead, with lattice girder work between, would be very strong to resist water pressure in the event of a compartment being flooded. Figs. 4 and 5 show such an arrangement. The bottom strake of plating is 25 per cent. more than the thickness required by Lloyd's. This increase has been made to provide for the greater corrosion which will take place at the bottom of the bulkhead. The remainder is $\frac{6}{20}$ths thick, being carried double to main deck. From main to upper it is also $\frac{6}{20}$ths thick, but single. This is considered thick enough. The weight of this arrangement in a midship bulkhead of a ship of 57ft. beam and 40ft. deep is not more than the single bulkhead constructed in accordance with Lloyd's rules. The double bulkhead need not be carried further above the water-line than to the main deck. It will be sufficient to carry a trunk from the main to the upper deck immediately over the pump, so that, to overhaul the pump, it may be lifted up bodily. For structural purposes this arrangement seems to be stronger than the ordinary one. For resisting water-pressure it is at least as strong, and, even if any leakage should occur from strain, the water can only get into the well or space between the bulkheads, in which space it can be dealt with by the pump without affecting cargo in the next compartment, and if not too great for the pump to cope with the leak, can be got at readily and stopped.

FIG. 4

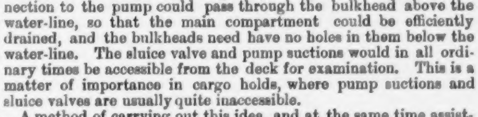

FIG. 5

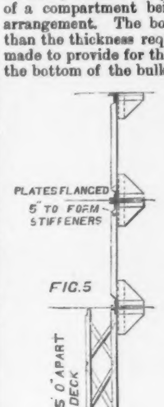

Other holes are made in bulkheads, though not at such a low position as for bilge or drainage pipes. Electric light wires, voice pipes, steam and other pressure pipes, all have to go through bulkheads. Of these, the steam pipes make the largest hole in a bulkhead; but in both war and large merchant ships they are usually high up, but not generally above the water-line. It would not be difficult to put steel trunks round the steam pipes, which could be made water-tight, and would tend to prevent water which got into a compartment from getting into an adjacent one through the hole made through the bulkhead for the steam pipes. Inside this trunk voice pipes and electric wires could pass. It would make the steam pipe as safe as a boiler from damage by gun-fire if this trunk were made about the same thickness as the boiler shell; and if the mountings not in this trunk were made of the same thickness and of tough metal, they would be equally capable of resisting the effect of gun-fire. This resistance, either in the case of the boiler or the horizontal trunk, would be considerable against splinters. Steam pipes have to be carried at a considerable height in large mail steamers, on account of the length of stroke of the main engines. Hence it is of importance for war purposes to keep the stroke as short as possible, and to keep the engines as low as possible in the ship. The smaller stroke of engine is accompanied by a smaller breadth of base, which allows the engines to be placed lower in the ship. The tandem type of engine is not a desirable one, and should be avoided in a steamer required for war purposes. Probably from a marine engineer's standpoint there may be advantages in this type of engine, but the disadvantages for war purposes are so great that the tandem type ought not to be allowed in mail steamers which are likely to be taken up in war time. On the contrary, some sacrifice of efficiency should be made, if it is necessary, by adopting shorter stroke and the non-tandem type. Engines of great power have been run for six days continuously at ninety revolutions per minute, and there seems to be no valid reason why this number of revolutions should not be considerably increased, and the stroke proportionately reduced.

(*To be continued.*)

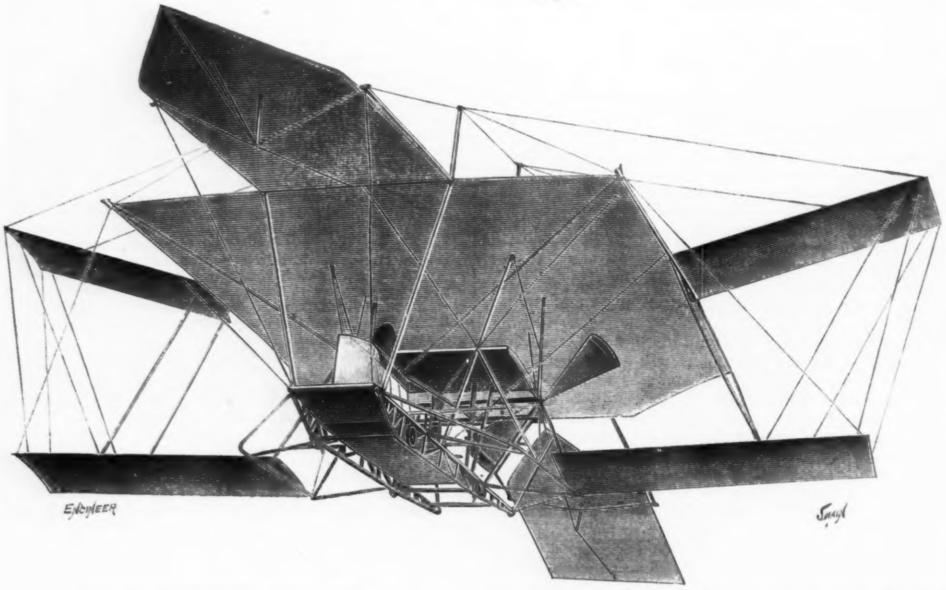
* Paper read before the Institution of Naval Architects on July 26th, 1894.

# MAXIM'S FLYING MACHINE—DETAILS

Fig. 2



## MAXIM'S FLYING MACHINE.

We are able this week to give some particulars and illustrations of Mr. Maxim's latest wonder. The success which recently attended Mr. Maxim's endeavours to propel a machine through the air is so marked that we think a description of this most remarkable contrivance will not just at present be out of place. It is not to be supposed for a moment that this machine approaches anything like perfection, but there can be no doubt that its performances considerably eclipse all previous efforts. Through the courtesy of Mr. Maxim we are enabled to here reproduce two views—one of the machine in flight, the other of the water-tube boiler used, with its casing removed—also a table showing the lifting efforts. The remaining diagrams are our own, and illustrate the principles of various devices which we shall proceed to describe; but before doing so we shall briefly glance over the occurrences of the 31st ultimo, on which occasion the soaring tendency of the machine became so great as to overcome all the obstacles which were designed to retain it near the ground, and Mr. Maxim found himself in a somewhat similar position to that of Frankenstein when overpowered by the monster which he himself had fabricated and endowed with life. This is what happened:—The machine had travelled some 1000ft., the latter 550ft. of which it had flown, a fact which is clearly proved by the impressions made on the inverted guard rails. It appears that suddenly the lifting effort became so great that the framework carrying the after-retaining wheels became distorted to such a degree that the wheels ceased to perform their office, and the after-part of the machine became free—the fore-part, however, continuing to hold the machine down, but not for long, as the wobbling which ensued rendered steering impossible, and the machine got out of line with the track. The left-hand front wheel also got free, and the machine charged against one of the timber supports carrying the right-hand guard rail, tore up the rail, which is simply a 9in. by 3in plank, and did very great damage to its own framework. The ride was in this way brought to a sudden stop, and it will be several months before it can be renewed. The total weight of the machine, including 600 lb. of water, 200 lb. of naphtha, and three men, was about 8000 lb.

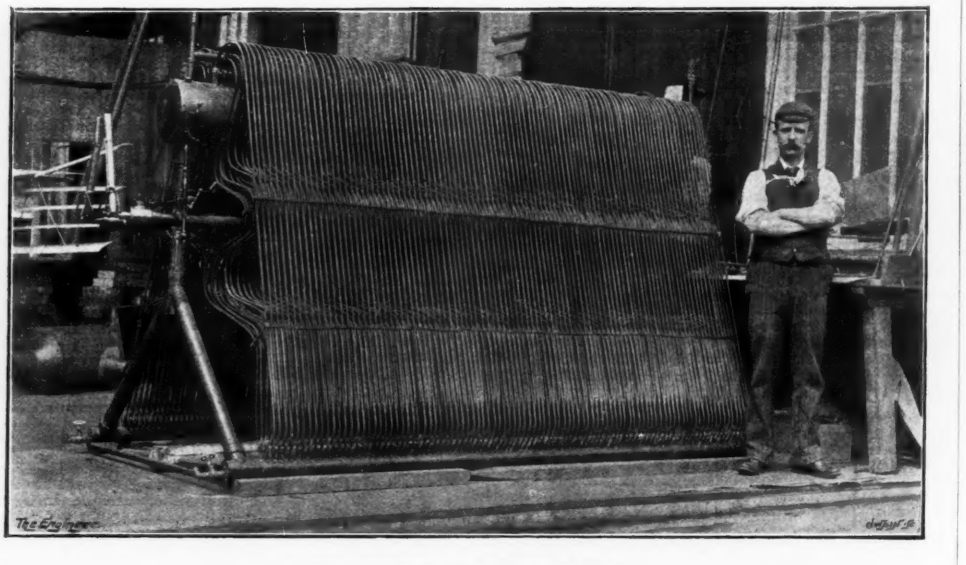


Fig. 4—MAXIM'S WATER-TUBE BOILER

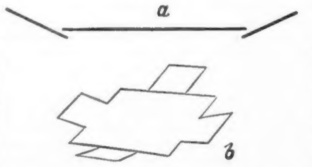
Fig. 1 shows the deck plan of the machine. P P are the two propellers mounted on the shafts S S, to each of which motion is given by a compound steam engine. B is the main boiler, delivering steam through the pipes MM. G is the gasoline boiler, which is kept charged with about 40 lb. of naphtha by a pump, $p^1$, automatically regulated, the supply being contained in the tank $T^1$, while the larger tank, T, contains the feed-water, which is fed into the boiler by the feed pumps *p*. W W W W are the wheels which run on the track before the machine has commenced to soar, and *w w w w* are those which were supposed to retain the machine by reason of the inverted rail above them. This they failed to do, owing to the too slender construction of the framing in their vicinity.

Above all this there is the great central aëroplane, with a surface of some 1400 square feet. This, with the side wings and the steering planes fore and aft, all taken together, have a total area of 5400 square feet. At the time of the trial the area was 4000 square feet, as six of the side planes were found unnecessary. Our view—Fig. 2—shows the machine as it was at the trial. The total width is 104ft., and the length 125ft. The angle of the steering planes, which is about 7·25 degrees, or 1 in 8, is controlled by a steering windlass, which when soaring turns them, very slightly, opposite ways, as *a* in Fig. 3, when the machine would soar whichever way it was being propelled. The total lift of the planes amount to 10,000 lb.

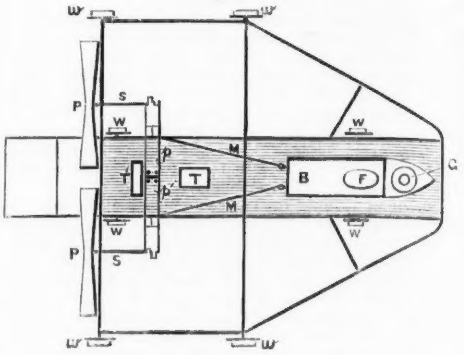
Fig. 3



Another valuable property of these fore-and-aft aëroplanes is their tendency to preserve the equilibrium of the machine in descent. To understand this, let the reader take a sheet of paper, hold it some 6ft. off the ground, and observe how it dives to the ground on being released. Now let him take the same piece of paper and cut away the four corners and bend up the sides, so as to resemble *b* in Fig. 3, and let it fall. He will see that it is quite another matter.

The boiler, Fig. 4, is a fascinating contrivance, replete as it is with so many novel features. It is a little like Thornycroft's, and a little like Yarrow's, but the tubes are necessarily much lighter and thinner than in either. Their shape is shown in Fig. 5. The water boxes at the bottom are $2\frac{1}{2}$in. diameter, [and $1\frac{1}{2}$ mm. thick. The water tubes are of copper, and about $\frac{1}{2}$in. thick. The total heating surface is about 800 square feet, the flame surface being 30 square feet. The Y downtake is 3in. in diameter. There is a forced circulation maintained by an injector in the upper leg of the inverted Y. This may be briefly explained as follows:—Water is pumped into the boiler at 330 lb. to the square inch. This escapes into the boiler through an injector nozzle, and as the steam pressure usually required is 300 lb., it follows that there are 30 lb. devoted to this circulation. The cold water coming in combines with the hot water, increasing the gravity of the water in the downtake, and down it goes, so that the water coming in is immediately taken to the hot tubes. The nozzle is provided with a spring which always maintains the 30 lb. difference in pressure. A very convenient apparatus is attached to the feed pipe, by which it is possible to see at a glance exactly how many pounds of water per hour are entering the boiler.

Fig. 1



A novel way of observing the height of water in the boiler is a thermostatic gauge, the principle of which we endeavour to show in Fig. 6. A gauge communicates with the interior of a bent tube, which is a boiler in itself. Its lower half is exposed to the flame of the furnace, the upper half lying in the drum below the water-level, and as long as this half is immersed the water within it will be at the same temperature as that in the drum, and therefore at the same pressure. But if it is exposed the pressure rises enormously, and consequently the needle also, and it is known that the water is low. There are no glass water gauges on the boiler, as this device supplies all that is wanted.

Fig. 6

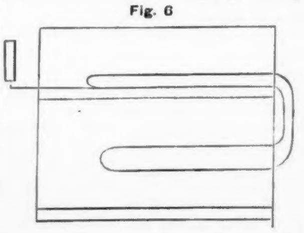


Fig 9

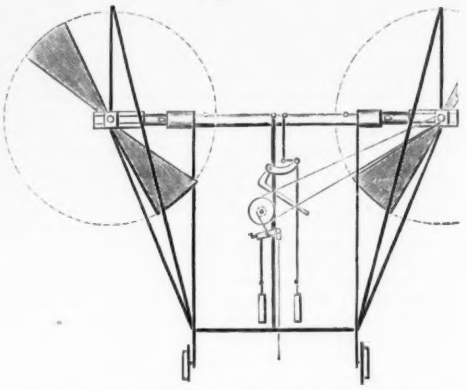


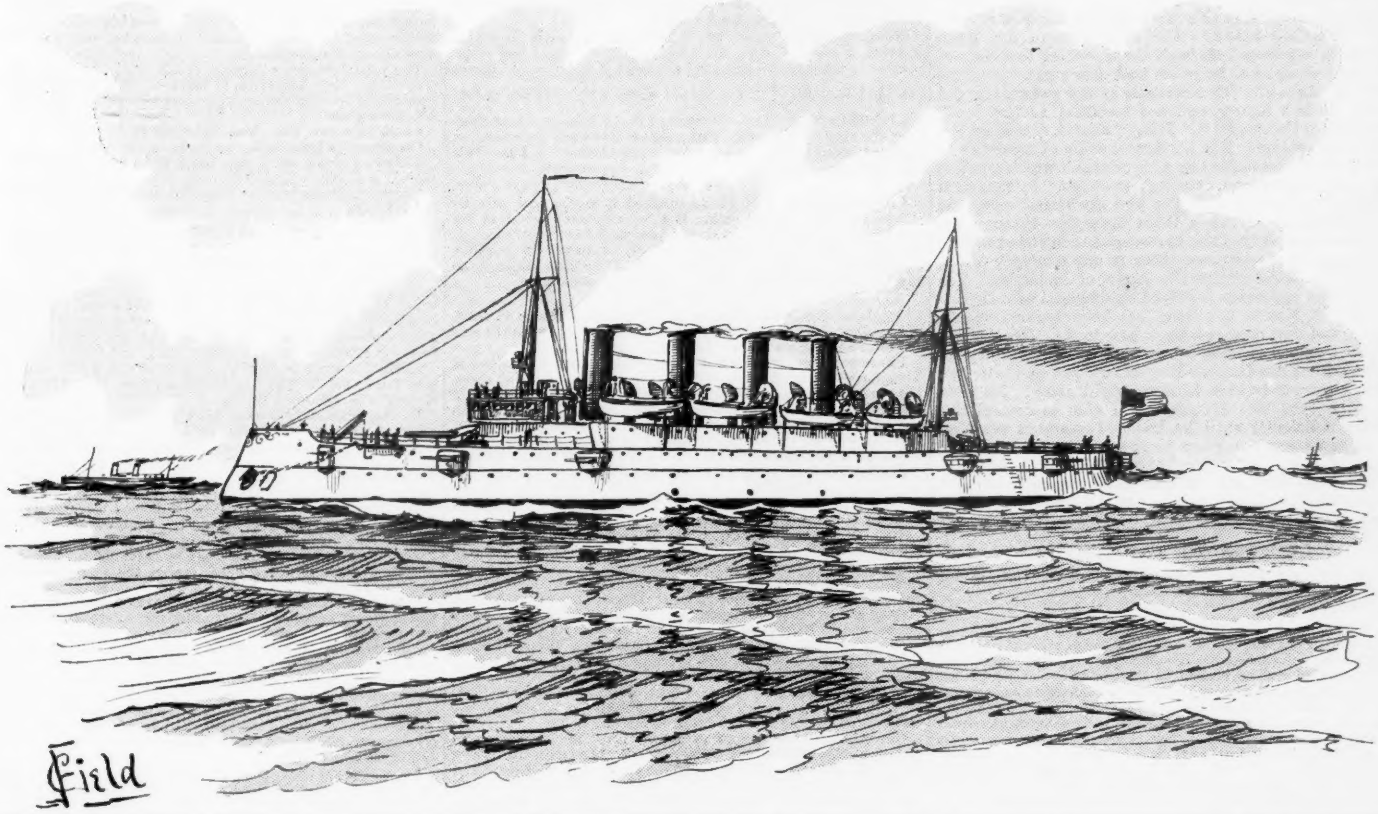
Over the upper part of the boiler there is a second system of smaller tubes, also of copper, $\frac{3}{16}$in. diameter and $\frac{1}{50}$in. thick, constituting the feed-water heater, which raises the temperature of the water to 250 deg. Fah. In this way the products of combustion having passed between the boiler tubes are brought into contact with the incoming water before escaping.

The boiler will and does make more steam than can be used. Its weight with its feed-water heater, casing, uptake, furnace, and water, is 1200 lb., 200 lb. being that of the water itself. The fuel employed is naphtha of 72 deg. Beaumé. This is heated in the gasoline boiler by a part of its own contents. and delivered to 7650 jets at a pressure of 50 lb. per square inch. The average contents of this boiler is about 40 lb. Figs. 7 and 8 show the devices by which an automatic regulation of its supply is obtained, which is found perfect.

It will be seen that the gasoline boiler is supported on one arm of a bell-crank lever, which is balanced with spiral springs, so regulated as to keep it floating when containing 40 lb. of naphtha. The entire generator and contents weigh 100 lb. If the boiler becomes overcharged, the increase in its weight sets in motion a system of rods and levers terminating at rod R in Fig. 8. P is here the gasoline pump rod, actuated by one arm of the rocking lever which derives its motion through the connecting-rod C from a crank-shaft driven by belt and pulleys off the port propelling engine. The rod R in actuating the bell-crank lever—one arm of which is shaped like a T—throws in or out of gear either one or the other of the fixed pawls which engage with the

## THE U.S. CRUISER MINNEAPOLIS

MESSRS. CRAMP AND SON, PHILADELPHIA, BUILDERS AND ENGINEERS



ratchet wheel, which in its turn, by means of bevel gearing, increases or decreases the radius of the arm to which the gasoline pump is linked, according to the direction of the ratchet feed.

The gas, when generated, passes through the furnace and then out at the other end of the steam boiler. It then enters the burner through an injector, and the fall in pressure from 50 lb. per square inch to 1 lb. per square inch is made to do work in sucking in air. A damper-shaped valve may be turned about so as to vary the air at will—full on blows the gas out, while with it closed, a great cloud of black smoke is given off at the smoke stack. With a proper adjustment the flame is a purple white, and about 22in. high.

Fig. 5

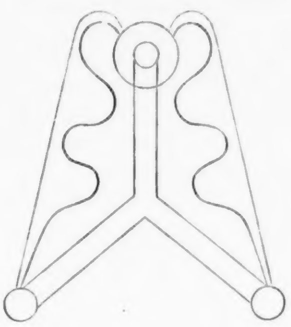


Fig. 8

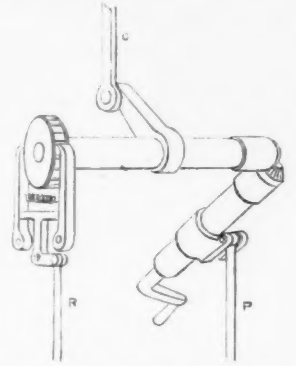

Fig. 7

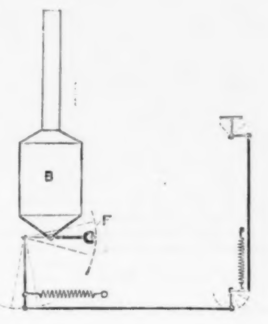

The engines are 363·63-horse power, and drive the screws—which are 17ft. 10in. diameter, each having two blades 62in. wide, with a 16ft. pitch, at a speed of 375 revolutions per minute, driving the machine at 40 miles an hour. Mr. Maxim estimates that 150-horse power is wasted in slip, 133·33 expended in actual lift on the angle of the aëroplanes, and 80·30 in driving the machine, its frame and wires, through the air. The screw thrust before starting has been found to be 2100 lb.—while running, 2000 lb.

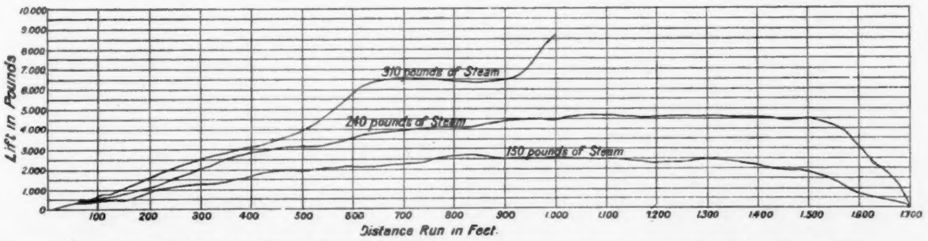

Fig. 11—Diagram showing Lifting Efforts of Maxim's Flying Machine during Three Runs made July 31st, 1894

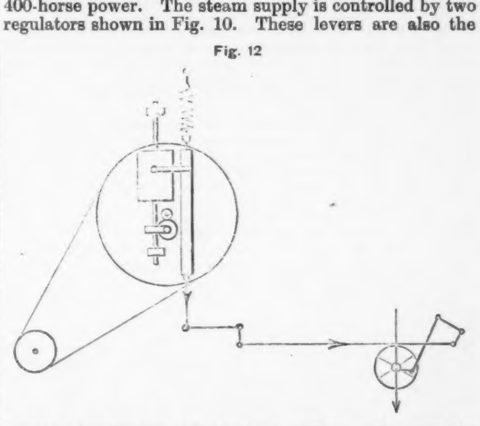
The engines are beautifully constructed; their position, with relation to the platform of the machine, can be seen by referring to Fig 9, which shows the methods adopted in working the pumps. The feed-pumps are driven from the low-pressure cylinder tail rods by means of bell-crank levers, the gasoline pump by means of a pulley mounted on a second crank shaft, which we have already mentioned. The feed-pumps work very fast, and pounding is prevented by a rubber bag on the suction very near the pump and spring pistons in the discharge. The quantity of discharge is regulated by varying the stroke by means of the hand lever shown. An indicating check valve shows exactly how much water is entering the boiler, the marking being in pounds per hour.

The engines weigh 600 lb., so that Mr. Maxim obtains more than 1-horse power for every 2 lb. of weight—which is in itself an achievement. The pumps weigh 100 lb.; the high-pressure pistons are 5·05in. in diameter; the low-pressure 8in. in diameter by 1ft. stroke. The high-pressure cut off is at ·75 of the stroke, that of the low-pressure being at ·625. The relatively high-pressure in the low-pressure cylinder is due to its earlier cut off, and to a large clearance in the high-pressure cylinder which is allowed in order to protect the cylinder from injury by water in case the machine should pitch. The ports and steam passages are unusually large. Piston valves are used with 3in. travel. The engines move with very little friction, owing to their exceeding lightness. The piston speed is estimated at 750ft. per minute.

An instance of the great care and forethought with which the engines have been planned lies in the construction of the big ends of the connecting-rods. The bolts which secure the brasses are hinged on the end of the rod in such a way as to allow of any slight bending, in the event of the strain on the framework of the machine bringing the crank out of line with the cylinder. It must be remembered that the engine, cylinders, frame, and rods, are entirely made from sheet metal, so that there is every possibility of there being necessity for some such safeguard as this. By-pass valves are provided, so as to allow live steam to pass directly to the low-pressure cylinders—thus if the steam pressure in the boiler should mount too high, it will blow past the high-pressure cylinders, instead of blowing off into the air, and the fall in pressure is made to do work in the exhaust from the high-pressure cylinders, drawing the steam from the high-pressure and driving it into the low-pressure, thus causing more direct pressure on the low-pressure than back pressure on the high-pressure. In this way the engines may be made to develope fully 400-horse power. The steam supply is controlled by two regulators shown in Fig. 10. These levers are also the steering handles for side steering. When going straight ahead they are both vertical. If it is desired to turn to port, the port handle is turned outwards, which slightly checks the steam supply to the port engine, and the machine necessarily turns. If the machine is to be stopped, both handles are thrown over simultaneously to the extreme positions, as shown by the dotted lines. So simple an arrangement as this admits of instinctive action, entailing absolutely no brain effort, and therefore gives the driver more time to think of other things.

Fig. 10

Fig. 12



The diagram given in Fig. 11 shows what occurred on the day of the disaster. The ordinates show the lifting effort in pounds, the abscissæ the distance in feet travelled. It will be seen that the dynograph ceased to record after a distance of 1000ft. had been covered. In other words—

this was the point when the crash came. Fig. 12 shows how the lifting effort is registered on the revolving drum of the dynograph, turning once round in 1800ft. The pencil traces a line on the paper, which indicates the pressure on one of the axletrees, both of which are fitted with dynographs.

All the framework of this extraordinary machine is composed of hollow tubes. The exhaust from the main engines is conducted through them out at the back of the main aëroplane, in order that the steam may not injure the canvas. The condenser is not yet a perfected detail. It is a luxury, and not essential to the flying properties of the machine. It is, of course, receiving Mr. Maxim's attention. The horizontal angle of incidence in flight is to be maintained by a "gyrostat," which consists of a gyroscopic wheel, rotating, suspended by universal joints, and connected with the two horizontal aëroplane rudders, so as to act upon them instantly—through the well known property of the gyroscope to continue rotating in the same plane—in case there is any tendency of the machine to deviate from the angle of incidence. The whole of the apparatus is stayed by diagonal wire ties.

What Mr. Maxim has done has been to, so to speak, make a bird that does not know how to fly. We believe that the safe use of such a machine will always depend on the skill of the driver. Because we put on skates, we do not expect to be able to skate right away. No more can we expect Mr. Maxim to be able to control this machine efficiently until he has had years of practice. In the same way there are birds who fly well and birds who fly badly. This bird has only just been hatched. Let us hope that Mr. Maxim will not come to grief, "Icarus like," before he is fully fledged.

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### CARNOT AND MODERN HEAT.

Sir,—In your issue of July 13th Dr. Lodge attempts to take up my challenge, but does not submit to the condition I laid down, that he was to confine himself to the use of ordinary logic and mathematics, and not employ his favourite mode of demonstration, namely, "oracular demonstration." He begins by saying that "a thing with constant specific heat has its intrinsic energy a linear function of its temperature." This is a dark saying, as oracular sayings usually are, and does not seem to me to have much to do with the question at issue. He then, incidentally, defines the absolute scale of temperature as "a scale on which heat and temperature are proportional." I am afraid that Lord Kelvin would not acknowledge this as a definition of his absolute scale.

Dr. Lodge then finishes his demonstration thus:—"Hence, allowing that a gas has no intrinsic energy at absolute zero, the statement is justified." What statement? Is it the statement that the scale of a constant-volume-perfect-gas thermometer agrees with the absolute scale? If so, the demonstration is to me unconvincing. What it does prove, if it proves anything, is that the intrinsic energy of a perfect gas is proportional to its absolute temperature.

Dr. Lodge then goes on to talk about some formulæ, none of which were used by me, and proposes to subdivide a term expressing work of expansion into internal and external work of expansion, which I, as a disciple of Lord Kelvin, object to, because, as Lord Kelvin says, we know nothing about internal work.

In the second last paragraph of his letter Dr. Lodge goes on to say that "Professor Alexander chooses to say *now* that his N was the specific heat at constant volume, the same as my *c*." What the force of the "now" is I do not see, as I am not aware that I ever called N aught else than "specific heat at constant volume."

Dr. Lodge then says that if my N means this, my appeal to Regnault's experiments was meaningless. A mistake it might be, but it was surely not meaningless. I admit that Regnault's experiments were made on the specific heat of air under constant pressure, not under constant volume. But to me it appears that if the specific heat under constant pressure is constant, that under constant volume is likely to be constant also, and has been proved to be so in different ways.

In his last paragraph Dr. Lodge returns to the charge again thus:—"Given a perfect gas, its temperature scale is the same as the absolute scale, and there is no difficulty." Difficulty about what? I made no references to a perfect gas.

At the beginning of his letter Dr. Lodge speaks vaguely about my having "curious ideas concerning the value of time." What he means by this I do not know, but would remark that he seems to place a higher value on time than on courtesy. Dr. Lodge seems aggrieved by some remarks I made in my last letter, but he has himself to blame for them. I never descend to personalities unless when provoked, when I give the offender a "Roland for his Oliver." Had he not made an unprovoked attempt to heap ridicule on my book I would never have mentioned his lack of civility in not acknowledging the receipt of a complimentary copy from the author.

I would remark that one who uses such a word as "extrapolate," which belongs to no language on earth, has little call to reproach others for using long words.

I apologise to Mr. Donaldson for insinuating that he had said that he did not lay claim to much knowledge of mathematics. I do not know how I came to think that he had said so. However, what I said was intended for praise rather than depreciation.

In reply to Mr. Donaldson's letter in your issue of July 20th, I may say that there are now no points at issue between Dr. Lodge and myself. My second letter was merely a castigation of Dr. Lodge for his reply to my first, and an acknowledgement of my failure to prove that the scales of the air thermometer, both constant pressure and constant volume, are the same as Thomson's absolute scale.

Mr. Donaldson asks me if I mean to say that 2lb. of cherries are numerically equal to 2lb. of beef. I reply, Yes. He says my illustration "is infelicitous, because all the members of the equations cited are of the same dimensions." What he means by this I do not quite understand. If, by the members of an equation, he means the two expressions equated, I admit that the two terms of the—single—equation I cited are of the same dimensions, but I do not see the objection to that, as it is always so in dynamical equations. In fact, this is often used as a check on the correctness of equations in dynamics and physics.

Mr. Donaldson says that "neither Professor Rankine nor Professor Alexander has made a mistake in first obtaining general expressions for the laws, and then deducing particular forms. The mistake they have made lies in the fact that they have not arrived at true general expressions for the laws." He then proceeds to say that he, in his work on "Water Wheels," has proved this statement with regard to one general formula of Rankine's. I cannot tell whether or not this is true, but even if it be, this does not prove that all Professor Rankine's general formulæ are untrue. Moreover, he does not prove that any of my general formulæ are untrue.

Mr. Donaldson next makes some remarks on the definitions of Thomson's symbol, M, given by Mr. Mansell, "Student," and myself. He then gives the value of M for a gas which he deduces from my definition: to wit,

$$M = p\,v \log \frac{v+1}{v},$$

and remarks on it that "not only is, therefore, M, but also its differential coefficient with respect to *t*, equal to a number of foot-pounds." Mr. Donaldson will at once see, when I direct his attention to it, that he has either mistaken the meaning of my definition of M, or that he has made a mistake in his deduction of its value for a gas, given above. The definition I gave was M = heat absorbed per unit increase of volume by a unit mass of air, whose temperature remains constant when it is expanding.

Now, Mr. Donaldson will admit that the expression "per unit increase of volume" does not mean during an actual unit of increase of volume, as he seems to have taken it to mean, but means the limit to which $\frac{\delta H}{\delta v}$ approaches when $\delta v + \delta H$ are indefinitely diminished. Here, of course, $\delta H$ denotes the quantity of heat absorbed by the body—unit mass of air—while expanding at constant temperature $t$ from volume $v$ to volume $v + \delta v$. With this hint he will find that

$$M = p.$$

In my definition of M I have confined it to air, as air was the substance I was dealing with. But for a general definition the word "air" in my definition should be replaced by "a substance." It ought to be observed that here the unit of heat is the quantity equivalent to a unit of work. But if Mr. Donaldson has access to my book he will find that there it is proved that for a gas

$$J\,M = p,$$

where J denotes Joule's dynamical equivalent of a unit of heat. Most scientists seem to think it most convenient to choose the unit of heat, so that J may = 1, as we have done above.

I have not seen Mr. Donaldson's expoundings of his opinions of Thomson's writings on heat derived from a slight study of them, but my own experience is quite the reverse, namely, the more I study Thomson's writings the more I am convinced of their truth and of the great genius and wisdom of the writer. I am not a blind admirer of Thomson, but when I do venture to differ from him I do so with bated breath.

Peter Alexander.

Sea Bank Cottage, Cairnryan, Stanraer,
August 6th.

### ENTROPY.

Sir,—Of the many letters on this subject which have appeared in your columns, perhaps the most sensible is that of Mr. Henry Cherry in your last number. He remarks very truly that the thermal condition of a body is completely determined by its volume, pressure, and temperature. I would be disposed to go further, and say that the thermal condition of a body is completely determined by its volume and pressure, and that its temperature, entropy, intrinsic energy, &c., are all functions of these. That is to say, given the volume and pressure of a body, we can from these determine its temperature, entropy, intrinsic energy, &c., provided we can properly define temperature, entropy, intrinsic energy, &c., and possess certain experimentally determined coefficients connecting the latter with the former.

Unfortunately the definitions usually given of "temperature" are not at all satisfactory. These are—(1) "The temperature of a body is its state or condition with respect to sensible heat;" and (2) "the temperature of a body is its tendency to communicate heat to other bodies." These definitions are quite as useless for scientific purposes as the definitions given by geometers of "a straight line." That is, they are of no use whatever. Whoever manufactures a satisfactory scientific definition of temperature will cover himself with glory. The definition which is implicitly used in the manufacture of thermometers is, "the temperature of a body is a thermal property of the body, which changes proportionally with the volume of a standard body, called a thermometer, of which the pressure is constant, the two bodies being in contact." This definition labours under two objections—(1) It does not say what temperature is, but merely says how its variations are measured; (2) the scale of variations is not absolute, but depends on the special properties of the thermometric body made use of.

Thomson's definition of absolute temperature labours under the first of these defects, but not the second. Some one may remark that the popular definition is always understood though not expressed, namely, "temperature is warmness." This, of course, is the original meaning of temperature. But how are we sure that the variations of the so-called temperature of a body indicated on any scale of temperatures correspond to, or are proportional to, the variations of warmness of the body? It will thus be seen that we cannot say what temperature is any more than we can say what entropy is. All that we can say in both cases is, how the variations of each are measured by the variations of the pressure and volume of the thermometric body in contact with the body whose temperature and entropy are in question. Perhaps the simplest definition of entropy is, "The entropy of a body is a thermal property of the body whose numerical value does not change unless heat is received or given out by the body, but at a given constant temperature of the body, increases proportionally to the quantity of heat the body receives, and diminishes proportionally to the quantity of heat the body gives out." From this definition it follows that if a body kept at absolute temperature T, receive or give out H units of heat, its entropy will increase or decrease by a quantity proportional to $\frac{H}{T}$, and if the units be properly chosen, the increase or decrease will be equal to $\frac{H}{T}$.

Mr. W. Oldknow very rightly, I think, objects to the use of the word property in connection with entropy, as it is not a property of matter, but is merely a mathematical convention. There are many such conventions, very useful in their way, which are so much used, that it is convenient to have names for them, such as "potential," "momentum," &c., and which, to save much circumlocution, are conveniently though improperly called properties of matter. No more has that which is commonly measured by expansion, and called temperature, any right to be called a property of matter; but as it is intimately connected with that property of matter called warmth or hotness, it is convenient to identify it with that property. I hope, therefore, that Mr. Oldknow will forgive me for my loose use of the term property.

Cairnryan, Stranraer, Peter Alexander.
August 3rd.

P.S.—I intend to say more about entropy on a future occasion.

### HEAT AND THE STEAM ENGINE.

Sir,—I respectfully ask your space for the purpose of presenting some views of my own regarding the heat and mechanical action of steam in an engine, which I have never seen in print.

The "total heat" of Regnault H = 1081·94 + ·305 T deg. is only the formula which he obtained by condensing steam of different temperatures. It is made up of the heat in the water, plus the heat which disappears during evaporation, leaving no trace except 5 or 10 per cent. in dynamic effect, according to the pressure under which it is evaporated. In the steam tables this dynamic effect should be credited to the latent heat, instead of to the total as we now have it.

The real heat units of the steam are equal to the heat units of the water from which it was raised. Thus provided with heat, the steam is able to expand itself, and do work according to the mechanical equivalent, under favourable circumstances, in a non-conducting cylinder without any condensation. The fact that the live heat in steam increases as fast or faster than the temperature, while the total heat only increases ·305 T deg., is a reason for the better economy in the use of the high steam and expansion, in comparison with the old low-pressure system.

After the steam is cut off in the high-pressure cylinder, the passage through ports, pipes, and receivers, and larger cylinders, and in the condenser, until it hits the tubes, is an act of expansion consuming heat. If we are lucky enough to have moving pistons in front of it, we get its value in work, if, as in the receiver to be noticed, we lose our pressure and heat and get nothing.

The following are some calculations which I have been making upon the results obtained by Professor Kennedy in his trial of the engines of the steamer Iona, in July, 1890, having before me the report published by your Institution of Mechanical Engineers.

The report says:—"The actual weight of feed-water used per revolution was 2·35 lb." This I find was obtained by dividing the weight of all the water put into the boiler by the number of revolutions during the test, and is quite misleading, as I shall proceed to show—noting first my approval of the detail work which enables us to correct the results.

The total feed-water is given as 136,820 lb., but it is subject to reductions. Supplementary, or make up, 8302 lb.; this was a consequence of leaks in boiler, or pipes, or feed-pump, and never went into the engine.

Steam pipe and valve chest drains 800 lb.

Condensation from high-pressure jacket 5600 lb.

Collecting these out, I get 8302 + 800 + 5600 = 14,702 lb., and 136,820 − 14,702 = 122,218 lb.

Priming 2·28 per cent. = 3504·7866 and 122,218 − 3504·7866 = 118,613 2134.

Revolutions for the trip 58,651 and $\frac{3504 \cdot 7866}{58{,}651} = 2 \cdot 0222$ lb. weight of steam per revolution used in cylinder.

On the high-pressure diagram, Plate 3, on the 110 lb. line, I get measurements from the steam curves to the compression curves which together make 2·88in.; length of diagram, 3·50in.; stroke of piston, 3·25ft.; volume of steam per revolution = 2·21ft. × 2·528 square feet piston area = 5·587 cubic feet; weight per cubic foot at 125 lb. total pressure, ·28422, and 5 587 × ·28422 = 1·587937 lb., which is 78·525 per cent. of the 2·0222 which went into the cylinder. The condensation, then, is 21·475 per cent., instead of 36·6 given in the report.

On the expansion curves of this high-pressure diagram the mean effective pressure is 33·2 lb. per square inch; piston area, 366 square inches; distance moved by expanding steam by piston per revolution, measuring from the intersection of the 110 lb. line with the expansion curves, 3·974ft. Then 33·2 × 366 × 3·974 = 48,288 88 foot-pounds work done in high-pressure cylinder by expanding steam.

For the work done in the second cylinder I take the mean pressure marked on the diagram 19 97. Piston area 899·17, piston travel 6·5ft., which give 116,716·75 foot-pounds.

From the low-pressure diagram I take the mean 7·175, and add the back pressure, 2 lb., which makes the total mean pressure above zero 9·175.

Piston area 2537·5 square inches, travel 6·5ft. The work done by expanding steam in this cylinder per revolution is 151,330·07 foot-pounds.

The receiver diagrams—Plate 5—show work done which costs heat but does not assist in turning the crank shaft. The first receiver I estimate at ·9 the capacity of the high-pressure cylinder, or 7·3 cubic feet; the mean effective pressure I find on Fig. 10 is 2·7 Then 2·7 × 144 × 7·3 = 2837·24 foot-pounds.

The second receiver I estimate at 18·3 cubic feet. Mean pressure on diagram Fig. 12, ·85 lb. per square inch, and ·85 × 144 × 18·3 = 2239·92 foot-pounds.

I now have for the total work done by expanding steam:—High-pressure cylinder, 48,288·88; first receiver, 2837·24; intermediate pressure cylinder, 116,716 75; second receiver, 2239·92; low-pressure cylinder, 151,330 07; foot-pounds, 321,412·86.

The heat necessary for doing this work I take from the Regnault table, 125 lb. pressure at cut-off. Heat in 1 lb. of water, 316 0433 units; terminal pressure, 5 lb.; heat in water, 130·8913 units; difference, 185·152 units; then as 2 0222 lb. went into the high-pressure cylinder, there are available for doing work by expansion 374·414 units. It may very properly be objected here that as 21·5 per cent. of the steam has been condensed at the time the steam valve is closed, I have no right to reckon its heat as available.

My answer is that all the condensation inside the cylinder is upon the cylinder walls, and that the heat units put into those walls during the first part of the stroke by condensation are exactly equal to the heat units sent out of them by evaporation later on, otherwise the cylinder would become hotter.

The jacket water I regard as condensed half only on the walls next the bore of the cylinder, consequently it gets only the heat due to the condensation of $\frac{5600}{2} = 2800$ lb. for the whole experiment. The heat of condensation for 150 lb. pressure is 860·5 units per pound weight, and $\frac{2800 \times 860 \cdot 5}{58{,}651} = 41 \cdot 3$ units per revolution. The available heat is 374·414 + 41 3 = 415·714 units. The work done by expansion is 321,412·86-foot pounds, and $\frac{321{,}412 \cdot 86}{415 \cdot 714}$ = 773·16-foot pounds work done per heat unit.

If my method of calculating should prove to be correct, it would follow that we can estimate from indicator cards the weight of steam going into the cylinder.

The report of the trial of the Meteor engine has no corrections which I can apply. Taking the diagrams as they are, and using the 6·93 lb. feed-water per revolution, as given, a similar calculation gives $\frac{862{,}701}{1118 \cdot 8}$ = 771-foot pounds per heat unit expended. This result should please Mr. Mansel.

The figures taken from a test made twenty years ago on a Leavitt compound pumping engine at Lynn, in this State, give total work 257,219·92 foot-pounds per revolution by expansion, and the heat used 323·76 units, which gives 794·44 foot-pounds per heat unit—and this should please Mr. Donaldson.

This fine little engine has both cylinders jacketed, with steam at boiler pressure 70 lb. It expands twelve times. Cylinders 17½in. and 36in. × 7ft. stroke, working on opposite ends of a beam. The indicated horse-power was 168·08, and the feed, including jacket water, was 14·783 lb. per hour per indicated horse-power.

William H. Harrison.

Braintree, Massachusetts, U.S.A., July 23rd.

### THE DARING AND THE HORNET.

Sir,—In my recent address to the Naval Architects at Southampton I stated that the speed of the torpedo-destroyer Daring was 29 368 and that of the Hornet 27·628 knots. In justice to the builders of the latter vessel, I desire to explain that the speed claimed for her was the mean speed obtained during a continuous run of three hours, whereas the speed of the Daring was the maximum speed of one mile with the tide.

May I ask you to allow me to call attention to this point in your columns? Brassey.

4, Gt. George-st., Westminster, S.W., Aug. 4th.

---

Sir,—Referring to the statement which has been widely circulated in the press, and repeated by Lord Brassey in his able address at the recent meeting of the Institute of Naval Architects, that the speed of the Daring was over 29 knots, we would point out that the speed referred to was that obtained on one run over the measured mile.

As we attach no importance to speeds on isolated miles, we make a practice of only putting forward as the speed of a vessel that obtained on a continuous trial of three hours on Admiralty conditions, and we would submit this as a fair basis upon which speeds should be placed before the public. On this basis we believe the speed of the Daring was $\frac{78}{1000}$ of a knot per hour greater—obtained, we understand, by about 300-horse power more—than that of the Hornet; and we are sure the builders of the Daring would not wish a comparison to be made in such a manner that the performance of their vessel should be placed in a more favourable light than the facts justify.

Yarrow and Co.

Isle of Dogs, Poplar, London, E., August 8th.

## RAILWAY MATTERS.

The West Highland Railway was opened for traffic on Tuesday.

The Barry Railway Company have just acquired land for extension of Barry Docks.

About forty-five miles of the Bareilly-Soron Railway project have been completed. This line will be a connecting link between the metric gauge systems north and south of the Ganges.

The estimated expenditure of 123½ lakhs of rupees on the northern section of the Mu Valley Railway in Upper Burmah from Choungzon to Mogaung, about 140 miles in length, has been granted by the Secretary of State.

A Great Northern goods train from Grantham to Leicester was wrecked at Leicester station on Monday last. The train dashed into the dead-end, smashing it to pieces. Three loaded wagons and vans were thrown on the top of the tender. One wagon containing eight cattle was thrown over the top of the tender, and six of the beasts were so badly injured that they had to be slaughtered as soon as they could be liberated. The guard, fireman, and driver were badly shaken. The cause of the accident is not explained.

Owing to the girders of one of the spans of the Anas Bridge being badly damaged during erection, the opening of the Godhra Rutlam Railway will probably be deferred till August. *Indian Engineering* says that the damage was caused by the timber part of the staging on which the span was resting catching fire, with the result that the girders dropped and were buckled out of shape. This accident must be very discouraging to the engineers engaged on this difficult structure, where the work has been vigorously pushed under very trying circumstances.

The breaching of the Begari Bund and the bunds on the Indus, between Sukkur and Sita road, is causing grave anxiety to the North-Western Railway officials. It is feared, and with good reason, that the railway line between Ruk and Jacobabad and the line between Sukkur and Ruk are seriously threatened. If Jacobabad, which is situated 40ft. below the level of the river, should be swept by the floods, the consequences will be most serious. The bridge over the Rohi Nullah, recently damaged by the floods, has been converted into a girder bridge and through communication restored.

The trains on the Great Western Railway were recently seriously delayed in consequence of a singular circumstance. As the corridor train to Kingswear was nearing Wooton Basset it was noticed, the *Railway World* says, that one of the lines had become bent and twisted owing to the extreme heat, so that it was unsafe for trains to pass over it. The authorities were communicated with, and in a short time the rails had been sufficiently repaired to allow of traffic being resumed; but had the circumstance not been noted before the passage of the train, it is probable that it would have given rise to a serious accident.

A memorial has been addressed to the Government by the British and Foreign Anti-slavery Society upon the question of giving a Government guarantee upon the capital required for the construction of a railway connecting the province of Uganda with the East Coast. Until this railway is made it is contended that any plan for the improvement of those countries must be of the nature of a makeshift. In addition to the merely commercial benefit to Equatorial Africa that would result from a railway to the coast, the committee would urge that its completion would greatly diminish the slave trade in Central Africa. It would also do away with the necessity for the employment of thousands of porters at present engaged in the transport of goods from the coast to the lakes.

The railway traffic on the London and North-Western Company's section from Manchester to Leeds was on Sunday last for the first time passed through the new tunnel under Standedge, a lofty portion of the Pennine chain between Diggle and Marsden, in Yorkshire. The new tunnel is three miles and seventy yards long, and has been constructed from the plans and under the direction of Mr. F. Stevenson, chief engineer to the company. It has been driven through gritstone rock and hard shale, and has been lined with hard bricks of Brindle make, of which over 25,000,000 have been used. Double lines have been laid in the tunnel at a dead level. The old pair of narrow tunnels carrying each a single line under Standedge will be closed for a time for inspection and repairs, and then all four lines will be constantly used.

In an article in the *St. James's Gazette* on "Progress in the Far East," we gather some useful information on railways in China:—"The Imperial Northern Railway of China has not been constructed for purposes of pleasure, it is essentially a strategic line. His Excellency Li Hung Chang, who had been mainly instrumental in developing the Kai-ping Collieries, saw the necessity of constructing a railway from Kai-ping to Tientsin. He lost no time in commencing work; and, being ably backed up by Tong-king-Sing and Claude W. Kinder, C.E., and others, the construction of the railway from Kai-ping was pushed on rapidly, and in 1886 the first section of the line—twenty-eight miles—was opened for traffic to Lu-tai, the extension to Tientsin—the maritime port for Peking, sixty-two miles—was completed in 1888, and the first special train from Kai-ping to Tientsin was run through by Mr. Kinder on July 25th, 1888. The following year the line was extended to Tong-ku, a mile from the Taku forts, at the mouth of the river Peiho. Early this year the line was opened for traffic to Shan-hai-kwan, 180 miles from Tientsin, the station at the former place being within 1000 yards of the Great Wall of China, through an opening in which the railway is being constructed towards Kin-chow, at the northern extremity of the Gulf of Liau-tung."

In an interesting article on "The Electrical Welding of Street Railway Tracks," contributed to *Electricity* by Mr. N. W. Perry, we abstract the following description of a process which has proved particularly successful:—"In making the standard weld, four blocks of iron are taken about 2in. square in section and shaped to fit the rail section. Let us assume that the welder is in position over the joint to be welded. The lower pair of chocks, as these iron blocks are called, are placed in position, the hydraulic jacks are worked and the clamps brought into position against the chocks and the proper pressure applied. The current is now turned on—30,000 ampères—and the chocks gradually heat up. The operation is watched very carefully, and the pressure increased or decreased as the requirements demand, until the required temperature, little short of that of fusion, is attained. The jack is now rapidly worked, bringing the necessary pressure on the chocks to complete the weld, and then the release valve is opened, and the clamps are withdrawn. The upper pair of chocks are next put in place and the operation repeated. The welder is now swung to one side, the clamp removed, and the face of the rail slightly hammered to smooth down any irregularities, and the operation is complete. Under favourable conditions the welding proper of a joint can be done in seven minutes, but it usually takes double this time. The machine is next swung over to the other rail, and the joint there welded. This being complete, the two cars—the dynamo and welding cars—move on to a second pair of joints, which are welded in like manner. They then move along the track, skipping the third joint, the one which, in laying the track, was left open, and proceed to the fourth. Thus, during the daytime every third joint is skipped, this being done to allow room for the expansion due to the welding heat. At night, when everything has cooled down, and the temperature is at its lowest, the welding machine goes over the track again, and completes the work omitted during the day."

## NOTES AND MEMORANDA.

In Liverpool there are 114 people to the acre; in Manchester 39 9; in Birmingham 38; Huddersfield having only 8. These differences are appealed to for explanation of the apparently high death-rate of Liverpool.

A new form of phonograph of a particularly simple construction has been described before the Electro-chemical Society of Berlin, by Herr A. Kœltzow. In this instrument, which in consideration of its low price appears suited to many purposes, at any rate in those countries where patent rights will not prevent its introduction, the cylinder on which the record is made is composed of a hard kind of soap. Each cylinder admits of being used for recording 250,000 words, since an arrangement allows of the removal of a very thin layer from the surface when this has been covered. Thus the cost of the cylinders for registering any number of words is not more than the cost of the paper which would be required if they were written down.

In a paper read before the Royal Society on "The Absolute Specific Resistance of Pure Electrolytic Copper," the authors, Mr. J. W. Swan and J. Rhodin, compared a large number of different specimens of electrolytic copper. Several of the specimens were at first roughly examined, and the best chosen for further investigation. The best of these were then electrolytically refined. This, without previous fusion, was drawn through sapphire dies to the requisite diameter, and the resulting wire subjected to careful measurements. The first specimen, "A," was measured both when hard and also after annealing at a red heat in an atmosphere of carbon dioxide gas; the second sample, "B," was only examined after annealing. The authors took extreme care in finding the dimensions of the wires and the temperatures at which they were measured. The values of the two specimens in C.G.S. units were as follows, the density being 8 9587 at 15 deg. C:—

| | | Absolute specific resistance. C.G.S. units. | Temp. coefficient. $\Delta t$. |
|---|---|---|---|
| Sample A. | Hard, as drawn | 1603 | 0·00408 |
| „ A. | Soft, as annealed | 1566 | 0·00418 |
| „ B. | Soft, as annealed | 1559 | 0·00415 |

Mr. Charles Baskerville writes as follows in the *Journal* of the American Chemical Society:—"In the recent literature which I have been able to consult, the separation of titanium from iron by means of sulphurous acid has been confined to the sulphates of these two metals. This process is long and tedious and often unsatisfactory. If a neutralised solution of titanium and iron chlorides of not too great dilution be boiled with an excess of sulphurous acid, the iron becomes deoxidised at once, and a white flocculent precipitate of titanium settles out. By this means the titanium is obtained free from iron and requires no re-solution and second precipitation, as is frequently necessary for purification when precipitated from the sulphate. If the sulphate be changed into a chloride by precipitation with ammonium hydroxide and dissolving again in dilute hydrochloric acid and neutralising the excess of acid with ammonium hydroxide, the separation is easily effected. The accuracy of the method is shown by the two following analyses: $TiO_2$, found, 0·0322; used, 0·0308. $TiO_2$, found, 0·0317; used, 0·0314. The tedious boiling with sulphurous acid is avoided. A clean precipitate, which settles well and does not cling tenaciously to the sides and bottom of the beaker, filters rapidly and easily washed with hot water, is obtained. Salts of aluminum remain in solution."

M. Roland, who has given much attention to utilising the artesian waters of the Oued-Rir Valley, has conceived the idea of investigating the law as to the increase of temperature with depth in the region of the Algerian Sahara, and with this object he has turned to account a series of thermic observations made during the sinking of numerous wells in the Oued-Rir Valley. He found that the water is at a level of about 75 metres = 41 fathoms, and that its temperature is 25·6 deg. C. = 78 deg. Fah., while at a depth of about 20 metres a stratum was encountered the temperature of which remains between 22 deg. and 23 deg. C. = mean 72 deg. Fah.; so that the temperature increases 3 deg. C. = 5·4 deg. Fah. for an increased depth of 55 metres = 30 fathoms, or, for an increase of 1 deg. C. = 1·8 deg. Fah., the variation of depth is 18 metres = 10 fathoms. He also found the same result in Ouargia, and remarks that it differs widely from that met with in Europe. This communication, observes M. Bresson, in connection with Professor Berthelot's project for a 4000-metre shaft, proves that a useful effect as regards the central heat would be much more rapidly arrived at in the Sahara than in the old continent. At a depth of 4000 metres, with an increase of 1 deg. C. for every 18 metres, and the probable progression of temperature in depth, one would soon arrive at a heat of from 300 deg. to 400 deg. C.

At a meeting of the Vienna Academy of Sciences, Dr. J. Hann submitted an investigation on the daily period of wind velocity on the summit of the Sonnblick—3100 metres—based on a careful and laborious calculation and discussion of anemometrical observations for six years, and also on the range on mountain limits generally. The minimum of wind force takes place on the Sonnblick very early, about 8 h. or 9 h. a.m., and the maximum occurs about 8 h. p.m. On the Säntis—2500 metres—the minimum also takes place relatively early between 10 h. and 11 h. a.m. But from the accepted theories of the cause of the daily period of wind force on mountain summits it might be supposed that the minimum would occur in the afternoon. He therefore examined the records for several other stations, and found that in the summer, for altitudes ranging from 1400 to 4300 metres, the mean time of the minimum occurred at noon. He then investigated these facts to see how they fitted in with the assumed causes of the daily range, and as he could not reconcile them, he suggests that the possible explanation of the daily range on mountain peaks may be that the surface of the mountain being much more warmed than free air during the day affects the anemometers. It is assumed, however, *Nature* says, that the chief effect is only active for a few hundred metres below the summit, in the morning, and that later it would be interrupted by the wind coming from the valley. If the minimum were due to the great ascending current, it would occur during the afternoon.

In a paper on the "Weathering Properties of Sandstones," by Mr. W. Bolton—*Dingl. Polyt.*—it is pointed out that the usual criteria for the quality of building stones, such as their strength in compression, their absorptive power for water, and their behaviour when tested for weathering properties in the conventional manner, are not always conclusive. In particular, the compressive strength of the stone is seldom of much value in judging quality, as even inferior stones possess a crushing strength much above anything to which they are likely to be exposed in practice. Attempts to rank building stones according to their specific gravity have proved quite illusory, as no connection can be traced between this property and their mechanical value. A similar negative result has attended endeavours to find a relation between the tensile strength of the stone, its capacity for absorbing water and the force of expansion of the latter which is exerted in freezing. Methods directed to the determination of the capability of stones to resist those influences known collectively as "weathering," comprise the examination of the porosity of the stone as indicated by the quantity of water that it will absorb under standard conditions, the attack of its soluble constituents by hydrochloric acid, and the observation of its behaviour when a liquid is caused to crystallise in its pores. The author bases his judgment on the analysis of the stone, especial attention being directed to the nature of the substances serving as binding material to the particles composing the bulk of the stone. Some practical experience and observation would perhaps be the most valuable.

## MISCELLANEA.

A complete installation of electrical apparatus for all kinds of cooking has been fitted and is employed in the Imperial Restaurant, Queen Victoria-street, this being the first in Europe.

A seam of bituminous coal, 5ft. 11in. in thickness, has been struck by Mr. Donald Munro, at Dungannon, Ireland. The depth at which the seam was discovered is 188 yards from the surface.

An extensive system of wharves is about to be constructed on the water front of the city of Everett, adjoining Boston, Massachusetts. The land necessary for this purpose embraces upwards of 250 acres.

A scheme is on foot for the erection of a steel rope suspension bridge across the River Wye at Sellach, Herefordshire. The plans show a suspension bridge with a clear span of 180ft., and necessary approaches to same.

The competition for plans for the new museum of Egyptian antiquities at Cairo is an open one. The plans must be handed in before March, 1895. The best plan will receive £E600, and the four next best £E100 each.

The Chadderton Ironworks Company announce that they have granted to Messrs. W. B. Haigh and Co., Ld., Oldham, the sole and exclusive licence to manufacture and sell the McDougall's steam saving appliances.

The thirty-mile canal, with the additional seven-mile tunnel driven through the western mountain range, by which a proper sewerage for the city of Mexico is at last to be obtained, and danger of inundations removed, has been formally opened.

The Mersey Docks and Harbour Board have decided to extend in a westerly direction the existing double line of rails on the quay at Birkenhead. They are also considering plans of the laying down of additional hydraulic supply pipes at Birkenhead.

Tenders are invited for laying a cable from Canada to Australia by seven different routes, in order that, in accordance with the wishes of the Intercolonial Conference, the fullest possible information may be obtained as to the cost of laying and maintaining a cable.

The proposed Wallasey embankment is intended to prevent the flooding of the low-lying ground inland. It is feared that if something is not done the sea will break through the sandbanks and flood the district of Hoylake and Wallasey, besides submerging the Wirral Railway.

At a meeting of the City Commission of Sewers, held on Tuesday last at Guildhall, Mr. Alderman Bell presiding, it was decided to make an improvement in Ludgate-hill, near the Old Bailey, and to sell for £500 a small isolated piece of ground in Widegate-street to the Jewish Board of Guardians, contiguous to their property.

The Government of India decline to sanction the extra staff applied for by the Burma Administration for forest work. Owing to the large areas of forest now being reserved, it is considered in Burma that a larger staff should be maintained, otherwise supervision cannot be satisfactorily carried out, and the results must necessarily suffer.

In connection with the autumn meeting of the Iron and Steel Institute at Brussels, the King of the Belgians has invited the members to a reception at the palace in Brussels on the evening of Wednesday, August 22nd. Upon the occasion of the visit to Liége on Thursday, the 23rd, the members are invited to a luncheon at the Jardin d'Acclimatisation of Liége by the Liége and Mons Societies of Engineers.

The death is announced of Mr. Charles Arthur Redl, at Chateau d'Oex, in Switzerland, on August 3rd, in the 81st year of his age, who deserves to be remembered as the original inventor some forty years ago of the dual system of signalling which led, after various developments, to that which is now in general use both in the army and navy. The value of the system was recognised by a special committee at the time, and Mr. Redl received from Government a considerable grant for his services in introducing it and instructing several young naval officers in its use.

Western Australia has an eye to the many improvements which engineering skill offers. Among the works about to be undertaken are the extension of the railway system from Southern Cross to Coolgardie, from Geraldton to the Murchison Goldfield, and from Donnybrook to the Collie Coalfields, the continuation of the harbour works at Fremantle, the conserving of and boring for water, the surveying and opening of roads, the extension of the telegraph system, and the improvement of harbours, jetties, and lighthouses on the coast.

The death is announced of Dr. C. R. Alder Wright, Professor of Chemistry at St. Mary's Hospital. Dr. Wright was known for the wide extent of his chemical researches and experiments. In 1878 he published his work on "Metals and their Industrial Application," and among his other efforts in metallurgy he assisted Sir I. Lowthian Bell in his researches on the chemistry of the blast furnace. More recently he made abstruse investigations in the field of organic chemistry, with special reference to the opium alkaloids and alkaloids of aconite. He also gave much attention to chemical dynamics, and was regarded as one of the ablest physical chemists of the day.

Two powerful steamers, which have been built for the Russian Government in connection with the Trans-Siberian Railway, now in course of construction, are intended to navigate rivers wherein there are rapids of such force that the ordinary paddle machinery would not be sufficient to overcome the force of the current. To get over this difficulty chain gearing is used. At each end of the vessel there are swinging arms and horizontal and vertical rollers to guide the chain from the time it enters at the bow until it is dropped over the stern after passing the hauling gear. The vessels will shortly leave for the Yenisei river. They are named the Pervoi and Vtoroi.

It is satisfactory to learn that the Forest Department in Burma are striving to effect an opening for Pyinkado timber for street paving, and with this view a note has been prepared on the properties of this wood, and copies and specimens sent to the Antwerp Exhibition. Scientifically Pyinkado is known as *Xylia dolaborisormis*, a large tree belonging to the order *Leguminosa*. *Indian Engineering* says the tree is very common in Burma and the supply of timber is only limited for use as railway sleepers. The breaking weight of one square inch in section and 30in. long is 318 lb., as compared with 208 lb. for teak and 209 lb. for oak. The crushing strain per square inch is stated to be 5208 tons, as compared with 3411 tons for oak and 2838 tons for teak.

A Newfoundland clergyman, the Rev. Patrick O'Brien, has invented an improvement in the hulls of ships, which, it is claimed, affords the maximum of speed and safety, and in a great measure avoids drifting to the leeward. The inventor, *Transport* says, curves the bottom of the vessel in convex form from stem to stern, and gives it a concave face from the keel to the sharp-edged bilge, while from the bilge to the top of the hull the sides are curved, presenting an outer convexed surface at the stern. In every case where a cross section is taken through the bilge, the sides and the bottom of the hull meet at an obtuse angle, and the outward inclination of the sides preferably increases from the ends of the hull. The steering qualities of vessels built after this plan are said to be greatly improved, especially in high winds which throw the hull over upon its side, as the bilge sections then serve as a side keel to hold the vessel to its course.

## DESCRIPTION OF TWIN-SCREW PROPELLERS WITH ADJUSTABLE IMMERSION FITTED ON CANAL BOATS.*

By Mr. Henry Barcroft.

*Canal boat propulsion.*—It is pretty generally known among those acquainted with canal traffic that until lately it has been impossible satisfactorily to navigate canal boats on the ordinary canals of the country by direct steam power; and boat hauling, except under favourable circumstances, is still carried on by means of horses. A canal barge is usually made as full in every dimension as possible, the limit being the size of the canal locks to be passed through, so that there is no space at the sides or stern for paddle or stern wheels, nor is there a space forward of the stern post available for a screw. Even if space were reserved here, it would admit of only a small propeller, too small in area to be effective at slow speed, and liable to get entangled in weeds. Nor would there be what is termed a "run aft," to allow a flow of water to supply the place of the water driven astern by the thrust of the screw. If a boat were well proportioned for carrying a large and paying load, the action of a common propeller would be in proportion prejudiced; and, instead of the massive boat going forward, the power would be wasted in driving a small current of water astern at a more or less considerable velocity.

*Conditions essential.*—In endeavouring to solve this problem in navigation, the writer regarded certain conditions as essential to success, which may be thus enumerated. First, that any mechanical means employed should be applicable to almost every existing boat, if possible without any structural alteration. Secondly, that any propeller when applied should not interfere with the passage as at present through locks and under existing bridges. Thirdly, that no cargo or crew space should be sacrificed. Fourthly, that the weight of the machinery should not seriously affect the carrying power of the boat. Fifthly, that the action of the propeller should not be prejudicially affected by weeds. Sixthly, that no wash should be originated, sufficient to affect injuriously the banks of a canal. For the purpose of attaching any kind of propelling machinery, these considerations exclude every part of a boat otherwise available, except the space at each side of the rudder; and the question then arose how best to utilise this space by the employment of propellers of sufficient area to cause the boat to go forward satisfactorily. The effort of every propeller expends itself in two directions, driving the water astern and the boat forward; and the definition of excellence given by Rankine is to the effect that, other things being equal, the best propeller is that which drives the greatest volume of water astern at the slowest speed. After many experiments, extending over two or three years, upon a 60-ton lighter purchased for this special purpose, the arrangement was evolved which is the subject of this paper, and which is found by experience to comply with all the foregoing stipulations.

*Newry.*—The last boat fitted, the Newry, is 62ft. long by 11½ft. broad, with 5½ft. draught fully laden, when, inclusive of machinery, she would have about 65 tons on board. Her machinery, weighing in all about three tons, consists of one locomotive boiler having 87 square feet of heating surface and weighing 23 cwt.; one horizontal engine with two cylinders, 4½in. diameter by 8in. stroke, placed on the deck immediately forward of the stern post. On each side, coupled to the crank shaft, are skew wheels 12in. diameter, driving wheels of the same diameter and of double the number of teeth on upright shafts, which are set in upright frames securely clamped to the foundation framing, and the foundation framing is secured firmly to the deck and deck beams of the barge. At the lower part of the upright frames are axles bolted or welded on at right angles, and upon these axles revolve the twin screw propellers, to which motion is conveyed by means of bevel wheels, one on the lower end of the upright shaft, and the other on the propeller boss. The interior of the boss is similar in design to what are called "patent axles" of road carriages, but suitably proportioned for the strains and work. The thrust is taken by a collar, on each face of which is a leather ring, the whole working constantly in oil, as is the case with all carriages. By this arrangement a saving is effected as compared with an ordinary screw working through a stern tube, which is necessarily subject to great friction. The diameter of the axle is 2¼in. and of the collar 4½in., giving an area of 12 square inches to take the thrust. The leather rings are each about $\frac{3}{16}$in. thick. The skew wheels used in this instance for gearing the engine crank shaft to the upright shafts are really worm gearing; the worm on the horizontal driving shaft has 16 threads of coarse pitch, having an inclination of 27 deg., while the worm wheel on the top of the upright driven shaft has 32 teeth inclined at the same angle to its axis or at an angle of 63 deg. to its face; hence the upright shafts and the propellers are driven at half the speed of the engine.

*Screw propellers.*—The twin propellers are 4ft. 10in. diameter, and have each three blades, and each blade has an area of four square feet; thus the total blade area is 24 square feet. The blades, made of thin steel, are riveted to arms, which in turn are screwed into or against the boss. The dimensions have been arrived at after numerous experiments, the great aim being to attain, subject to certain limitations, the utmost possible progress of the boat in proportion to the amount of coal consumed. The pitch of the blades is equal to 1000 revolutions per mile, and at full speed the propellers make 100 revolutions per minute. It is not asserted that the diameter or area or pitch of the screws is absolutely the best; but from experiments with various diameters, areas and pitches, the writer is unable to suggest any decided improvement, so long as the power and piston speed, &c., remain constant. Every change in these last would naturally involve a reconsideration of the proportions throughout.

*Crew.*—The crew consists only of a man and a boy, who have had no difficulty in handling the boat and machinery under all the varying circumstances in which they have from time to time been placed.

*Ulster.*—The Ulster, built a year ago, and similar in many respects, has now accomplished 3000 miles. Sometimes in Lough Neagh she has encountered considerable seas. On the Ulster Canal she has navigated up to Clones, eighty-one miles from Newry, through sections of 91 square feet, or only half as large again as her own immersed section; and in the Newry Canal she has passed through weeds so thick as to meet across the water; altogether the navigation from Newry to Clones is as difficult as any to be met with. These boats are very efficient as tugs. The Ulster towed a lighter laden with coal from Newry on the coast to Benburb on the Ulster Canal, a distance of 46 miles. The united cargoes of the tug and the lighter amounted to 107 tons. In this trip a length of 13½ miles in the Bann River and Lough Neagh was done in 4½ hours; the revolutions of the propellers were approximately 14,580 each, the revolutions due to the distance being 13,000; the coal consumed was 2¼ cwt. The leathers in the nave of the propellers had not been examined up to the end of May, although the tug had run 2350 miles; on examining them in June the author could see no wear on them, and the propellers are at work again without any change having been made. One cause which may tend to diminish their wear the writer is inclined to think may be that the pressure on the teeth of the lower mitre wheels transfers part of the thrust to the footstep of the upright shaft, thereby relieving the leather rings to that extent.

*Immersion of propellers.*—The propellers, which have never been wholly submerged, are readily raised and lowered, so as to regulate the immersion and thus secure the utmost efficiency. If they are too low, the engine is held by the increased resistance of the water, and the revolutions are restricted; while if they are too high, the engine runs away owing to diminished resistance, and a loss arises from excess of slip. The boatmen soon get to know the level that gives the best results, which for a full boat with 5½ft. draught is about 3ft. 3in. to 3ft. 6in. from the surface of the water down to the bottom of the propeller. The two propellers are adjusted independently of each other. A portable crane is dropped in a socket cast in the bed-plate at each side, and a long screw is hooked to a ring on the propeller frame; on slacking the clamping eyebolts the frame is suspended from the crane, and is then raised or lowered by the screw. Other methods have been used, but this plan has been selected as convenient and inexpensive, as well as being light and portable. It is a peculiarity of these partially submerged propellers that they have little or no influence upon the steering of the vessel; that is to say, if one propeller were going ahead and the other astern, they would stop the way of the boat, and not tend to turn her round. For going ahead the propellers in all cases turn towards the stern post in the upper half of their revolution. In place of twin propellers, a single propeller has been used with good results, though working on one side of the stern instead of centrally. Two, three, and four blades have been tried; all are effective, but two cause an undesirable vibration; three are most efficient, while with four blades the vibration ceases, but the efficiency is somewhat lessened, owing probably to what is called churning the water. If desired the whole propelling apparatus can be made portable, and readily moved from one boat to another. The only alteration that is needed for an existing boat is an extension of the stern post, so as to set the rudder farther back; a space of from 15in. to 21in. is needed between the stern sheeting and the rudder when put square across: and most boats can pass the locks with this addition.

*Performance.*—In April last the Grand Canal Company, Dublin, fitted their No. 34 lighter with machinery similar to that above described. The first voyage was from Dublin to the Shannon and back, having another boat No. 35 in tow. The distance there and back is 158 miles, with 78 locks. The second trip was over the same distance, and the time occupied about six days. In this trip the coal consumed in the double journey was altogether three tons at 14s. 6d. per ton, or at the rate of less than 1¼d. per boat per mile. On the Grand Canal it is usual to work night and day with relays of horses and men, and the time required out and back is five 24-hour days; the regular charge for hauling of 1s. per boat per Irish mile would be equivalent to nearly 9½d. per English mile. So that, without working at night, the steam tug was only one day behind the horse boats in a week, notwithstanding that about fifteen hours were lost by the steamer in waiting for the locks to be filled after she had passed through and for the subsequent passage through of her consort.

*Machinery.*—The propeller bosses and arms have from the first been manufactured by Messrs. Grice and Harrison, axle makers, of Birmingham. The blades and all the rest of the machinery for the Newry and for No. 34 lighter were constructed by Messrs. Robey and Co., of Lincoln, who have kindly supplied the accompanying drawings.

*Driving by petroleum engine.*—The new propellers seem admirably adapted for almost any method of driving. (The author described an arrangement by which power is derived from a petroleum engine.) Here the engine is represented on deck, 12ft. forward of the rudder; it rises only 2ft. 8in. from the deck, thus enabling a light boat—that is, one without cargo—to pass under low bridges. If, however, the nature of the navigation should make it desirable to put the engine below, this can be readily done.

*Hilda.*—A very suitable arrangement has been adopted by the Portadown Carrying Co. for their steam lighter the Hilda, 80 tons burden, which navigates Lough Neagh, the largest lake in the United Kingdom, being twenty-four and twelve miles in extreme length and breadth. Also the Lagan Canal to Belfast, where bridges are met with so low that the arch is but 2ft. 4in. above the deck of a lighter when empty. No option remained but for the boiler, made by Messrs. Victor Coates and Son, to be put below. On deck, close to the upright shafts, are the engines, one for each propeller, which were supplied by Messrs. Vosper and Co., of Portsmouth.

*Electricity.*—A desirable combination would be to introduce electricity for conveying power from an oil engine, placed in any suitable part of the vessel, to the propellers. The engine could drive a generating dynamo, which in turn could set in motion a motor wound on the cross horizontal shaft. By means of resistance frames, various speeds could be obtained and reversing be accomplished, as on an electric railway.

---

[*] Paper read before the Institute of Mechanical Engineers at Manchester on Wednesday, 1st August.

## BRITISH SOCIETY OF MINING STUDENTS.

### MEETING AT CARDIFF.

This Society, which is a stepping-stone to the Mining Institute, and has been in existence about seventeen years, held its annual meeting on August 1st and 2nd at Cardiff. The gathering was not a large one, but was thoroughly representative of all the coalfields in the kingdom, throughout which and the Colonies the 229 members of the Society are scattered. The business meeting took place on Wednesday morning in the lecture hall of the South Wales Institute of Engineers, the chair being taken by the President—Mr. Frank Brain, M.E., Assoc. Inst. C.E., of Gloucester. In his address he dealt at length with the report of the Royal Commission upon coal dust in mines. As to the recommendation that high-class explosives should be used in preference to gunpowder, he said that experiments made went to prove the improbability that dangerous explosions of coal dust alone could ever be produced by contact with an ordinary flame; and high-class explosives had failed to cause explosions of coal dust. Taking into account the cost of the electric fuse, the cost of high-class explosives was somewhat higher than gunpowder, but as the result of increased consumption, these he believed could be produced to compare favourably with gunpowder even from an economic standpoint. There was no doubt that electricity was the coming power in mines. In the colliery he was connected with they had three electric pumps working underground, and he could speak with confidence of their utility. His company was also putting down a system of underground haulage, worked by electricity, and scarcely a week passed in which they did not hear of some new electric plant in mines. It was their duty to apply themselves to the discovery of means to the prevention of accidents in mines. Last year there were over 1000 lives lost by mining accidents, and although this compared favourably with years gone by, there was still room for improvement, and they must minimise mining dangers by putting into practice what they learned. The president was re-elected, and also the secretary and treasurer, Mr. H. F. Bulman, Newcastle-on-Tyne. The following were appointed vice-presidents:—Mr. Hy. Palmer, Newcastle; Mr. H. W. Hughes, Staffordshire; Mr. C. H. Cobbold, Yorkshire; and Mr. R. B. Mawson, Lancashire. The remainder of the day was spent in visiting Cardiff Castle and Barry Docks.

Thursday was occupied in visits to the Llanbradach and Great Western Collieries. Llanbradach, which is about ten miles to the north of Cardiff, was reached by brake, and the visitors were conducted over the colliery by Professor W. Galloway, consulting engineer, and Mr. Bradford, manager. This colliery is the newest in South Wales, and is at present producing 500 tons a-day, work on the steam coal having just commenced at a depth of over 500 yards. There are two shafts, one 572 yards, and the other 584 yards deep. The roads are lighted by electricity, and natural ventilation is maintained, small fans being in use to complete the circulation of air in the extreme of one or two headings. One of the first mechanisms inspected by the visitors was a rubbish tipping apparatus actuated by compressed air, by means of which trams containing from two to three tons are, by means of a revolving frame, simply and easily turned upside down, and their contents deposited on the slopes of the rubbish tip. The screens were next examined. These divide the coal into five different classes suitable for various markets, and allow the rubbish to be picked out by hand on picking boards and a revolving table. Descending into the house coal seam, 264 yards deep, the party saw in operation a triple expansion duplex steam pump, raising 30,000 gallons per hour to the surface continually, and Jeffery's coal heading machine and rotary rock drill, both employed at the face of one of the headings, which is being driven 6ft. high by 14ft. wide, at the average rate of about 18 yards per week. Staus' skeps and Fisher's catches were shown on both shafts, a tandem compound winding engine on No. 2 pit, and the boilers, hauling engines, &c., were also examined with interest.

A long but pleasant drive brought the party through Cilfynydd—the scene of the Albion Colliery disaster—to the Rhondda valley, where the Great Western Colliery is situated. Here they were warmly welcomed and hospitably entertained by the management, represented by Mr. Hugh Bramwell, agent; Mr. John Vaillant, chief surveyor; Mr. F. Bell, assistant surveyor, and Mr. Forster Brown, jun. There was not time remaining to make a complete inspection of these extensive collieries, from which over 2000 tons of coal per day is the average output. This is raised from four pits, viz., the Hetty, No. 2, Tymawr, and Maritime. The latter, which has a Waddle fan 25ft. in diameter, is situated across the Rhondda river, and owing to the lateness of the day was left out of the programme of inspection. The visitors were conducted through the above ground works of the other pits, which are in close proximity to each other. Amongst other interesting items examined was a newly arranged chain creeper at the Tymawr pit. By means of this, full trams are conveyed from the pit tops to the screens, a distance of 100 yards, and are returned empty on the other side, thus effecting an immense saving of labour. The creeper is driven by an engine on a lower level. A very fine new winding engine by Fowler, of Leeds, was also seen at the pit; it is compound horizontal, having high-pressure cylinder 32in., low-pressure cylinder 48in., with 5ft. stroke, and automatic expansion gear worked by a governor. The steam pressure is about 150 lb. per square inch. This engine has a cylindrical drum of 18ft. diameter, and the depth of the pit is 500 yards, this being the deepest of the four pits belonging to the Great Western Colliery Company. The air compressors were also seen in operation. There are two pairs of tandem compound engines in one house, each pair having two high-pressure cylinders 22in. diameter, and two low-pressure cylinders 40in. diameter; stroke, 5ft. The air cylinders, 34in. diameter, are placed behind each low-pressure cylinder. Each high-pressure cylinder has variable expansion apparatus, which can be adjusted while the engines are working. There is an independent condensing apparatus, consisting of a pair of engines having 10in. cylinders, 20in. air pipes, and 2ft. 6in. stroke, so arranged that they can be worked together or as single engines and condensers. The mine is ventilated by about 270,000 cubic feet of air per minute with a Schiele fan of 15ft. 6in. diameter, driven by a compound condensing engine, and there is a separate condenser with 3in. water gauge at bank. Returning to the offices, the system of working the mine was explained by Mr. H. Bramwell. The long wall system is in operation. The general principle is to drive main or water levels to the pit bottom, and from these levels headings are driven to the roads, from which the stall roads are turned and the entire seam is taken out, except the pit pillars. The visitors expressed thanks to the colliery officials and returned by rail to Cardiff, and thence to their several destinations.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

The South Staffordshire Coal Trade Wages Board have taken steps to put themselves in shape with the reduction in colliers' wages which the National Federation have agreed to. A meeting of the Board has been held at Dudley since my last, and the coalowners announced that with the view to a revision in wages they must require that the net average selling prices of coal and slack over the last three months—May, June, and July—should be "taken out" by the accountants to the Board. It is anticipated that this return will show that the employers are entitled to a reduction of between 5 and 10 per cent., and under the sliding scale the men will have to submit to it. The miners' representatives have given their consent to the average being ascertained, but complain that the masters are not better organised amongst themselves so as to prevent the underselling that the men assert is going on. The reply of the masters to this, as urged at the meeting by Sir Benjamin Hingley, M.P., the chairman of the South Staffordshire Ironmasters' Association and one of the leading coalowners of the district, is that the Midlands have to contend with Scotland, the North of England, North Staffordshire, Lancashire, and the South Wales districts, and as in these districts wages and coal prices are being reduced, it is idle for Staffordshire to remain single. To do so would be to lose its trade both in coal and iron. Not one-tenth of the ironmasters were making a profit now, and the furnaces in Shropshire were losing upon every ton of iron. Other iron-making districts of England had far greater natural advantages than Staffordshire, and it was necessary to do everything possible to meet the severe competition from those quarters.

In North Staffordshire and Warwickshire the colliers are showing a good deal of dissatisfaction over accepting the 10 per cent. reduction decreed by the National Federation. At the collieries of the Shelton Iron, Steel, and Coal Company, North Staffordshire, the men and boys, to the number of nearly 2000, at first struck work, and it was only after a long explanation and considerable persuasion on the part of the local agent that they consented to go down the pits. At the Northwood Colliery a similar thing occurred, and at the Park Hill Colliery, Longton, and the Ford Green Colliery, the pits were also rendered idle. This week, however, the men are exhibiting a more reasonable spirit, and the holidays seem to have had a pacifying effect. In Warwickshire the men openly expressed themselves against accepting any reduction, and, had the local agent wavered for an instant in his commands to them to obey the Federation settlement, they would certainly have struck. As it is, however, the agent's advice is fortunately being accepted.

The great Federation coal strike in the autumn of last year against the attempt to reduce the 40 per cent. wages advance, which affected all the other central districts of England, but left South Staffordshire, which works under the Wages Board, untouched, proved a good thing for many of the dividend-earning collieries hereabouts. The affairs of the great Sandwell Park Colliery Company, West Bromwich, is a conspicuous example. At the annual meeting a few days ago the directors congratulated the shareholders on an exceptionally prosperous year. The colliery was very busy, and there was an advance in prices. As a result a 10 per cent. dividend, with a bonus of 5 per cent., had been earned, besides adding to the reserve fund and carrying forward a substantial balance.

The best—thin—sheet iron and tin-plate making concern of Messrs. Knight and Crowther, Kidderminster, announces a trading profit on last year of £10,743, out of which a 6 per cent. dividend is recommended on ordinary shares, £2000 is placed to reserve, and £2154 carried on. The total reserve fund now stands at £9000.

Several of the local railway wagon and carriage companies have just issued their annual reports. Messrs. Brown, Marshalls and Co. report a profit on the year of £9573, to which has to be added £5164 available from last year. A dividend of 10 per cent. on the ordinary capital is recommended, with £2000 to go forward. The Metropolitan Railway Carriage and Wagon Company recommend a similar division out of an available total of £22,979. Of this amount £14,294 is profit on the year, and £8684 the amount brought forward. This year £8000 is carried on after paying the dividend. The Midland Railway Carriage and Wagon Company pays a 7 per cent. dividend on the ordinary stock and 6 per cent. on the preference, besides which it places £5000 to the reserve, and carries forward £2000. The year's gross profits of this concern was £27,539, but after deducting £5500 for depreciation on wagons on line, the net profit comes out at £23,602.

## NOTES FROM LANCASHIRE.

*(From our own Correspondent.)*

*Manchester.*—Throughout both the iron and coal trades of this district the outlook continues about as unsatisfactory as it could well be. Only in exceptional cases do engineers report new work of any weight coming forward, and except that some of the heavy branches are fairly well off for orders, the position remains one generally of but very moderate employment, with really no indication that any material improvement can be expected in the near future. In the iron trade business still drags on slowly from hand-to-mouth, and a remarkable indication of the present extreme depression of trade is the fact that notwithstanding the almost entire suspension of production in Scotland, prices are scarcely appreciably affected even for north country brands of pig iron, whilst local and district brands have been gradually easing down, and continue weak. In the coal trade much the same condition prevails; the Scotch strike has been the means of taking away some of the surplus supplies from this district, but it has not enabled any materially better prices to be obtained, and so far as the local demand is concerned there is a more or less general giving way to meet the keen competition in the market to get hold of any business stirring.

The Manchester Iron Exchange on Tuesday was moderately attended, but an almost complete absence of inquiry was again the general report. With regard to raw material, users, as a rule, buy only in the smallest possible quantities for immediate requirements, and although makers' quotations are unchanged, prices for the most part still show a want of firmness. For local brands of pig iron it is scarcely possible to give any really definite quotations, as Lancashire makers are so altogether cut out of this market by the much cheaper district brands, that where any transactions are put through—and these are mostly very small lots for special customers—prices are a matter of arrangement rather than of list quotations. District brands remain much as last reported, Lincolnshire being still quoted at about 38s. for forge to 39s. for foundry, and Derbyshire about 43s. up to 45s. for foundry, net cash, delivered Manchester, but these figures can scarcely be said to represent the minimum that has been taken in some instances to secure business. Outside brands offering in this market are about stationary at recent quoted rates, good foundry Middlesbrough averaging about 43s. 10d., with some makers still quoting 44s. 4d. net cash, delivered Manchester, whilst for Scotch iron there is so little offering, that it is difficult to get quotations at all, but Eglinton remains nominally at about 46s. 6d., net prompt cash delivered at the Lancashire ports.

Here and there manufactured ironmakers report rather more business stirring in bars, some of them being now fairly off for orders, but no improvement in prices can be reported except that buyers who have here and there been endeavouring to place their orders at £5 5s. have been unsuccessful, although for specially favourable specifications a trifle under £5 7s. 6d. would no doubt in some instances be accepted. The actual quoted prices, which most makers are holding to, remain at £5 7s. 6d. for Lancashire, and about £5 10s. for North Staffordshire bars, delivered in this district. In other descriptions of finished iron business continues extremely slow. In sheets there is little or nothing doing, and prices if anything are easier, local makes being obtainable about £6 17s. 6d. to £7, and Staffordshire sheets are offered at as low as £7 2s. 6d. to £7 5s., delivered here. Hoopmakers' report an almost complete absence of business, but they still hold to the association list rates of £5 17s. 6d. for random and £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

In the steel trade the position remains much as reported recently, all descriptions of raw material meeting with a very slow inquiry, with prices weak, ordinary foundry hematite being obtainable at 52s. to 52s. 6d., less 2½, and basic steel billets at £4 net cash, or a trifle less for delivery here. Local makers of steel boiler plates report a cessation of inquiry, and although Scotch makers are necessarily just now out of the market, £6 10s. represents the full figure that could be got for delivery in this district, with here and there sellers at £6 7s. 6d. per ton.

Amongst the engineering representatives attending the Manchester Royal Exchange on Tuesday, the chief matter of discussion was the visit of the Institution of Mechanical Engineers during the previous week, and the opinion generally expressed was that the whole proceedings had passed over very satisfactorily. In not a few quarters there was, of course, considerable regret that the members of the Institution would not see Lancashire under very favourable circumstances, as regards activity in the large engineering establishments that were thrown open for inspection, but this in no manner stood in the way of their hospitable entertainment wherever they went, and the full opportunities afforded of seeing all that was to be seen, in the shape of modern engineering and mechanical progress, throughout the district. Apart from excursions and visits to works, perhaps one of the events which will be most pleasantly remembered in connection with the Institution summer meeting was the special performance at the Theatre Royal; where the whole of the boxes, dress circle, and stalls had been reserved by the local committee for the members. The theatre was very tastefully decorated for the occasion; sumptuous arrangements for refreshment were provided, and the entire evening's entertainment was evidently thoroghly appreciated by a very full house.

An extremely quiet tone continues to be reported throughout the coal trade, and there is a gradual easing down in prices, although it is exceptional where any actually quoted reduction on list rates is officially announced. The leading colliery concerns in the Manchester district have found it necessary to give way upon their list rates, to meet outside competition, whilst there is some easing down in other Lancashire mining centres, and stocks here and there are being pushed upon the market at rather lower figures, whilst competition from Yorkshire and other neighbouring colliery districts continues excessively keen. For all descriptions of round coal there is only the most limited demand, so far as inland requirements are concerned, and where pits are working more than three days per week a considerable portion of the output is going into stock. Quotations nominally are unchanged from last week, but it is exceptional where more than 11s. is now being got for best Wigan Arley, 10s. for Pemberton 4ft. and seconds Arley, 8s. for common housefire coals, and 7s. for steam and forge coals at the pit mouth. Engine classes of fuel also continue plentiful, and are obtainable at very low figures, common slack being in some instances as low as 3s. 6d. to 4s., with good medium sorts about 4s. 9d. to 5s. 3d., and some of the best descriptions still quoted at 5s. 9d. to 6s. 3d. per ton at the pit.

A fair amount of business is still reported in the shipping trade, so far as cargoes for Scotland are concerned, both in round coal and engine fuel. For ordinary descriptions of common round coal prices remain at about 9s. per ton, but for slack rather better prices have been got, 5s. 6d. to 6s. being now about the average figures for delivery at the Garston Docks, or the High Level, Liverpool.

*Barrow.*—There is still a quiet tone in the hematite pig iron trade, and the holiday season has tended to make business quieter than ever. The effect of bad trade is showing itself in the stoppage of the Solway Works. Only thirty-five furnaces are now in blast, and the make of the district, as shown by the fact that 2532 tons of pig iron have gone into warrant stocks this week, is too large by the yield of four furnaces. Stocks have now accumulated to 158,333 tons, being an increase of 63,710 tons since the beginning of the year. Practically nothing is doing in the forge and foundry iron trades, and the business in Bessemer qualities would be small were it not for local consumption. Prices are easy at 43s. 8d. net cash warrant sellers, and 43s. 7d. buyers. Makers quote 44s. to 45s. for mixed Bessemer numbers, net f.o.b., but they report a very small trade.

Iron ore is very quiet, and orders show no improvement either on home or general account. Ordinary sorts are as low as they can get in price at 8s. 6d. per ton net at mines.

The steel trade is very indifferently employed. The only department in which there is any activity is that of steel plates, which are in fair demand, and orders for which makers are holding to a satisfactory extent. Steel rails are in poor demand. There is practically no home demand, and the foreign and colonial inquiries are very small. Other branches of the steel trade are quiet, and there are no inquiries of moment for any of the specialities of production in this district.

Shipbuilders are still very busy, as also are marine engineers. In the course of a few weeks the torpedo boat Destroyer Sturgeon, built at Barrow for the Admiralty, the first launched of three, will be ready for her trials. As these steamers are being fitted with Mr. Blechynden's patent boiler, some interest attaches to the speed trials. No new orders are reported for ships or engines.

Coal and coke are a quiet trade, and late prices rule.

The Furness Railway Company has declared a dividend of 1 per cent. for the half-year, compared with 1½ in the previous half, and 1 per cent. in the corresponding half of last year.

The Naval Construction and Armaments Company has declared a dividend of 1½ per cent. on the past half-year, making, with the interim dividend paid January 1st of 2½ per cent., a dividend for the year of 2 per cent. The directors report bad trade, but say they are now well off for orders.

Shipping is quiet in every sense. The exports of pig iron and steel from West Coast ports during the past week have been 20,514 tons, compared with 17,718 tons in the corresponding week of last year, an increase of 2796 tons. The shipments to date this year have totalled up to 462,676 tons, against 458,935 tons in the corresponding period of last year, an increase of 3741 tons.

## THE SHEFFIELD DISTRICT.

*(From our own Correspondent.)*

Little change calling for record has taken place in the South Yorkshire coal industry this week. The trade done at Barnsley was very discouraging, although a fair number of agents were present. This being the first week of the trial of the maximum and minimum wages settlement arrived at by the Conciliation Board, it will be regarded with interest by both sides. It is to be regretted that no material effect has been produced by this settlement. Buyers will not purchase until they see an alteration in the present tone of business, and they are no doubt holding their hands in hope of a further reduction in rates, but it is generally understood that this will not take place. Prices are now at the low-water mark, and reduction on the present rates would place coalowners in as bad a position as they were before the settlement was arranged. A little obstruction has been met with at some of the pits, but it is hoped that as soon as these grievances are amicably arranged there will be better trade all round, and contracts, which are at present being negotiated for, will be placed. This is the view held by manufacturers, and it is hoped that it will be realised, and put the South Yorkshire coal industry on a sounder basis than it has been for the last year or two. The quotations are as follows:—Yorkshire, best, 9s. 6d. to 10s. per ton; Silkstones, 9s. 6d. to 11s.; Barnsley house, 8s. 6d. to 10s. 3d.; Flockton, 8s. 9d. to 9s. 6d. per ton; other qualities from 1s. to 1s. 6d. lower. Steam coal is in fairly good request, and the tonnage forwarded to Hull and the other Humber ports is well maintained. The railway companies are also taking increased quantities. Barnsley hards make from 7s. 9d. to 8s. 6d. per ton; inferior qualities from 1s. less. Gas coal is quiet and lower rates are looked for. Plentiful supplies of manufacturing fuel can be had at low rates, and the trade for that class of coal is dull generally. Good slacks command from 4s. to 5s. per ton. Coke in better demand at 9s. to 11s. per ton. Stocks at several local collieries are very heavy, and customers are urging a light demand as a reason for pressing reductions. The gas companies have not, in all instances, fallen in with the idea to maintain prices. The owners of the gas coal pits at first contemplated an advance of 1s. 6d. per ton on the old rates. This they modified to 1s. and subsequently to 6d. per ton; even the lower reduction has, in some instances, to be abandoned, and at least one large company has placed a considerable portion of its contracts at the old rates. There is no other reason to be given for this except that coalowners, in their anxiety to get work, have been underselling each other.

The colliery owners of Derbyshire, Nottinghamshire, and Leicestershire met at the Midland Hotel, Derby, last Monday, to hear from their local representatives on the Conciliation Board a full explanation of the terms of the settlement of the 19th of July as to miners' wages. Mr. Alfred Barnes, of Chesterfield, presided, and after Mr. Salmond and Mr. Deacon, two of the local representatives on the Conciliation Board, had made their statements, it was resolved: "That one-fourth of the advances given since 1888 should be taken off all classes of labour, above ground and under ground." This resolution is in effect carrying out the terms of the agreement which stipulated first that a reduction of 10 per cent. should be taken off the 40 per cent. advances obtained in 1888.

Some activity is shown in the Sheffield railway trade departments, particularly in regard to rolling stock. The most recent orders placed in the Sheffield district are with Messrs. Craven Brothers, Darnall, who have booked as follow:—The Metropolitan Railway Company, fifteen goods wagons and cattle trucks; South-Eastern Railway Company, fifty-two third-class carriages, third-class brakes, and composite carriages; the Cheshire Lines, forty-seven third-class carriages, third-class "picnics," third-class brakes, and goods brakes.

There are some slight symptoms of movement in the heavy trades. Manufacturers here are believed to be better off than in the northern and southern districts, where depression is reported as more acute every month. Crucible steel is being sent to the Continent in larger quantities, one or two of our Sheffield houses being busy on that account. Prices of hematite, Bessemer billets, and Siemens-Martin steel remain as last quoted. Makers expect to resist the attempts of buyers to lower quotations. With the improvement in railway material already noted, some additional inquiries have been received from shipbuilding firms. Bessemer billets and special carbons used in the Sheffield trades make from £5 7s. 6d. to £5 10s. per ton; bar iron, £5 10s. to £5 15s., both at makers' works; hematites, delivered in Sheffield, 51s. to 52s. 6d.; ordinary iron sheets, £8 10s.; ordinary wire rods, £5 5s.; rope rods and high carbon rods, £8 8s.

The war between China and Japan, if it does not have such an abrupt termination as it had commencement, is expected to cause a demand for military material. Considerable orders were recently received from Japan for both rails and armour plates, but the latter were spread over a considerable period. Some years ago a number of officials of high rank from China witnessed, at one of our large works, the operations of the Maxim gun. On the strength of these trials the Chinese Government had several Maxim guns of unusual size manufactured for them. These have not yet been heard of in the present conflict. It is understood that the Japanese have also been able to obtain similar ordnance, and they have certainly had their ships fitted with machine guns, which were used in their recent engagements, but so far nothing has been heard of the Maxim or the Nordenfelt guns in the land struggles.

The lighter industries are, if anything, duller than last reported. It must be remembered, however, that this is the "off" season, and there is not likely to be any improvement until the autumnal demand sets in from the metropolitan and kindred markets. There has been a good season in agricultural implements, mining and navvies' shovels, spades, &c. A speciality in shovels are those made from Mr. R. A. Hadfield's special manganese steel, which are manufactured by Messrs. John Bedford and Sons, Mowbray-street. These shovels are said to have shown exceptional powers of endurance. Tools manufactured six months ago have shown very little perceptible wear, and give every satisfaction to the users. There has been very little business done in the light edge-tool trades. Austria Germany, and Hungary are ordering more freely in razor and file steel. A change for the better is further reported in the rolling mills. The South American States are showing remarkable recuperation, considering the revolutionary and financial troubles which have prevailed so long. The Australian market does not recover so rapidly as was expected.

The increased dock dues put in force by the Manchester, Sheffield, and Lincolnshire Railway at Grimsby, are being opposed by the fishing-smack owners, and the Grimsby Smackowners' Association is agitating against them. A deputation met the directors of the railway company at Sheffield on Tuesday, and, after hearing the views of the Grimsby people, the directors promised to lay the whole matter before the Board on Friday —to-day.

The annual meeting of the Cutlers' Company, Sheffield, was held on Monday last, the Master Cutler, Mr. George Howson, presided. Mr. Charles Henry Bingham, of the firm of Messrs. Walker and Hall, Electro Works, Howard, was elected master, with Mr. H. Herbert Andrew as senior warden, and Mr. Maurice George Rodgers as junior warden. The only alterations made in the constitution of the company were the election of Mr. John Bedford, of Mowbray-street, in the place of Mr. Henry Harrison, J.P., deceased, and the election of Mr. Sydney Jessop Robinson, managing director of Messrs. William Jessop and Sons, in the place of Mr. William Jessop, who retires. The Master Cutler elect will be installed on the first Thursday in September, and the Cutlers' Feast will follow at a later date in October or November.

## THE NORTH OF ENGLAND.

*(From our own Correspondent.)*

No improvement can yet be reported in the iron and allied trades of this district, because labour difficulties still paralyse business. If the moulders' strike could be settled there might be some chance of a better demand. It seems anything but satisfactory that the strike of such a comparatively few men should throw so many others out of employment. There are not more than about 1500 moulders and pattern makers actually engaged in the strike, but their action has thrown out of work not far short of 20,000 other men in the district. The joiners in the shipyards in the North of England, after having been on strike for about ten weeks for a considerable advance on wages, and after driving away to the Continent much work which would have fallen to their share, have abandoned their claim and gone back to work at the old rate of wages where the masters can find employment for them. The moulders, however, are more obstinate; they have been idle since March—over twenty-one weeks—and while they at first claimed an advance of 3s. 6d. per week, they subsequently reduced their claim to 2s., and to that they still adhere, notwithstanding that there can be no doubt that whatever revival there was in the early part of the year it has disappeared now, and the action of these moulders has done much to kill the improvement. Instead of getting an advance the moulders ought now rather to submit to a reduction. It can hardly be doubted that the prices of castings are far too low to admit of increased wages being paid, and while work was certainly more plentiful when the strike began than it had been for a long time, yet realised prices had not moved up. The moulders have been told by other trades unionists that their action was too hasty, and that more work was not synonymous with increased profits. Some efforts have been made this week to bring about a settlement of this regrettable dispute, the masters having met the representatives of the men to discuss the situation; but even if the matter were settled at once, it would be some weeks before that would have an influence on the iron, steel, and shipbuilding industries, because their work on the contracts now in hand is much in advance of the moulders. With the exception of the Durham miners' strike of 1892, there has not for very many years been a dispute which has been more injurious to the trade of the North of England than the present strike of moulders. These moulders have done their best to prevent the importation of castings from other districts, but within the last few days some have been brought from Scotland, and even the Continent, which has enabled some firms to go on with pressing work.

The pig iron demand in the North of England is very dull for this time of the year, and the production continues in excess of the requirements, as it was in June and last month. It is likely to continue so during this month, as August is usually a quiet period, and more is it likely to be so this year, when the strikes have intervened to reduce the local consumption. On Tees-side there are the race holidays to interfere with the deliveries, and as the production is maintained, there being more blast furnaces in operation than at any time this year, it can readily be judged that the stocks will increase. That is most unsatisfactory at a season of the year when we look for decreases instead of increases. Last month, with good shipments and no holidays to reduce the local consumption there was an increase of 9745 tons in Cleveland iron stocks, and in June the increase was nearly as much. This month local consumption is less than it was last month, as more of the finished ironworks and foundries are closed, some altogether, and others will be so only for the race holidays. The position, to say the least, is not encouraging, but it is worse for the makers of hematite iron than it is for the producers of Cleveland iron. There is less chance of their making a profit, because their prices have fallen much more heavily than those of Cleveland iron. Thus a short time ago makers of East Coast hematite were able to get 45s. 9d. per ton for M. Nos., now they can barely realise 42s. 9d., a decrease of 3s. per ton, while Cleveland No. 3 has only fallen from 36s. to 35s. 6d., or 6d.; and what makes matters worse is that the cost of production has not fallen in proportion to the decline in prices. Coke is as dear as when the higher rates ruled, and Rubio ore has only dropped 6d. to 9d., the present price being 12s. per ton delivered Tees. Nevertheless, the output of hematite pig iron appears to be increasing, two furnaces having been set on last month, one a furnace which has just been re-lighted by the Normanby Ironworks Company at Middlesbrough.

Most of the makers of Cleveland No. 3 pig iron continue to quote 35s. 6d. per ton for prompt f.o.b. deliveries, a figure which they have kept unchanged for more than a month, and special brands cannot be had under that, but there are makers and merchants who will accept 35s. 4½d. No. 1 pig is about 37s. 6d., and is scarce. Cleveland ordinary warrants have changed very little in value for several weeks, and since our last report have not varied above 2d. per ton, a condition of affairs which does not tend to induce speculation in them. The stock of Cleveland iron in Connal's stores on Wednesday night was 96,061 tons, or 669 tons increase this month. Consumers do not care about buying when they can get makers' iron just as cheap. No. 4 foundry pigs are at 34s. 6d., and grey forge are at 34s.

A third firm of pig iron makers in the North of England has this month adopted the three-shift system at their works, viz., Messrs. Cochrane and Co., Ormesby Ironworks, Middlesbrough. This is the only firm in Cleveland as yet to introduce the system, the other two firms being located in South Durham. The Cleveland Ironmasters' Association disapproves of the concession, and Messrs. Cochrane severed their connection with that organisation, in order that they might be free to act as they desired. They have had to increase the number of shiftmen by one-fifth, viz., from 143 to 175, but they will pay nothing extra to the men for the shifts worked on the Sundays, and each blast furnaceman will have one Sunday in three quite clear of work.

The men's demonstration to agitate for the eight hours' day is fixed for Saturday, and work will be suspended at the furnaces from 6 a.m. Saturday to 6 a.m. Sunday. The demonstration is to take place at Middlesbrough, and the procession is to start opposite the Municipal Buildings at 1 p.m. Work is not to be suspended at those furnaces where the eight hours has been granted.

The Cleveland ironmasters' return for last month proved to be even more unsatisfactory than had been predicted. It is not usual at this time of the year to have increases in stock reported, yet last month there was an increase of 9745 tons, and in June one of 9178 tons. The cause, however, does not lie in increased make or diminished exports, because there is a decreased production of Cleveland iron and increased shipments, especially to the Continent. The increased stock is due to the smaller local consumption, which is one of the results of the moulders' strike. The stock was raised to 173,411 tons, of which makers held unsold 76,789 tons—12,504 tons increase on June—while in makers' stores 1215 tons were held—120 tons decrease—and in Connal's stores 95,392 tons—2639 tons decrease. At July 31st there were 94 furnaces in operation, 1 more than at June 30th, and 1 more than on the corresponding date last year. Of these 51 were producing Cleveland pig iron—1 less than at June 30th—and 43 hematite, &c.—2 more. The production of Cleveland pig iron was 123,114 tons—619 tons less than in June—and of hematite, &c., 129,517 tons—2024 tons increase—the total production of pig iron being 252,631 tons, or 1405 tons increase. The return shows that pig iron shipments from Middlesbrough were 4516 tons better than in June and 11,428 tons greater than in July last year.

Nothing new can be stated as to the condition of the finished iron and steel trades, and the engineering industries continue to be injuriously affected by the strike of moulders. The engineers have abandoned their claim, but they cannot get back to work as long as the moulders keep out. In order, if possible, to obviate the necessity for the closing of the Darlington Steel Works, the men were asked whether, if orders were obtainable, they would be prepared to work at lower rates of wages, but such a course is not permissible according to the rules of their union, and thus they could not give an answer in the affirmative. At the Eston Steel Works the wages sliding scale, which has been in existence for some years, has been renewed until June 30th, 1896. Mr. William Jenkins, who for twenty-five years has been the general manager of one of the most successful of our British industrial concerns—the Consett Iron and Steel Works—has resigned his position through ill-health, and the shareholders have made him one of the directors. Mr. David Dale, the chairman of the company, is to have £1000 a year as remuneration for his services, in addition to his share of the sum annually voted by the shareholders for division among the directors.

The coal trade shows much better features than the iron trade, for most of the collieries are fully employed, and deliveries are heavy, both on inland and export account. Coke for blast furnace purposes is in better demand than supply, even though only a small quantity is being sent to the Scotch works, and 12s. 6d. per ton delivered on Tees-side is as little as will be taken for a good coke.

Messrs. John Abbot and Co., Park Works, Gateshead, are taking advantage of the lull in business caused by the moulders' strike to effect certain improvements in their engineering department. They will almost completely reconstruct their large fitting shop, and will put in additional machinery and appliances. It is intended to increase the output of the tube and chain making departments.

At the Southwick Engineworks, Sunderland, a new pattern shop is being erected, and at the Palmers Hill Engineworks the boiler-making department is being extended. It is reported that the Weardale Iron and Coal Company has purchased the engineering and wagon works carried on at Darlington by Major Davison, who is retiring.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE is no improvement in the iron trade, and none can be expected until there is a settlement of the dispute with the miners. The strike has now lasted for six weeks, and it has had the effect of completely paralysing not only the coal industry, but also the iron and steel trades, while almost every other branch of trade has suffered more or less. The Lord Provost of Glasgow having been appealed to, has been endeavouring this week to bring masters and men together with a view to a settlement. The Associated Masters have declined to meet the representatives of the men, as they are fully determined to continue their resistance to the advance of 1s. per day, for which the strike took place. Several coalmasters who were outside the Association have conferred with the leaders of the men, and a proposal has been made to the latter that the miners should resume work at the old rate of wages, the masters giving them a guarantee that no further reduction of wages shall be made during the next twelve months. While these efforts are being made towards an arrangement, great distress prevails throughout the mining districts, especially in the more populous localities of Lanarkshire.

The pig iron market was closed on Monday owing to the holiday. It might, indeed, be shut one half the week just now for all the business that is being done. A few transactions have taken place in Scotch warrants at about 42s. per ton and in Cleveland at 35s. 4½d.; the hematite market is extremely dull.

The prices of makers' iron are as follow:—G.M.B. f.o.b. at Glasgow No. 1 43s. 6d. per ton; No. 3, 42s.; Monkland No. 1, 47s.; No. 3, 42s. 6d.; Carnbroe No. 1, 47s.; No. 3, 46s.; Clyde No. 1, 50s.; Gartsherrie No. 3, 50s.; Calder and Summerlee Nos. 1, 56s.; No. 3, 50s.; Coltness No. 1, 57s.; No. 3, 52s.; Glengarnock at Ardrossan No. 1, 52s. 6d.; No. 3, 48s.; Eglinton No. 1, 51s.; No. 3, 46s.; Dalmellington at Ayr No. 1, 50s.; No. 3, 46s.; Shotts at Leith, No. 1, 55s; No. 3, 51s. 6d.

The shipments of pig iron from Scottish ports in the past week amounted to only 2564 tons, compared with 5688 in the corresponding week last year. Of the total, the United States took 6 tons; South America, 50; India, 20; Australia, 375; Italy, 260; Germany, 20; Holland, 30; Belgium, 200; Spain and Portugal, 111; China and Japan, 280; other countries, 60; the coastwise shipments being 1152, compared with 2379 in the corresponding week.

The inland consumption of pig iron is greatly curtailed in consequence of the strike. It is confined pretty much to foundries, which in the main prefer Cleveland pig iron to Scotch, owing to its relative cheapness. The imports of Cleveland iron into Scotland in the past week were 3545 tons, compared with 4711 in the corresponding week, a decrease of 1166 tons, but there is a total increase in these imports for the year to date of about 27,000 tons.

The output of pig iron has been further reduced by the blowing out of four furnaces that were making basic pig at Glengarnock, there are only seven blowing in Scotland, against 11 last week, and 67 in the corresponding week of last year. The seven furnaces in operation are all making ordinary iron, three at Coltness and four at Shotts.

There is nothing to report with reference to manfactured iron and steel, except that the works continue closed, and one or two additional firms are discharging their clerical staffs. The market for finished iron and steel is practically closed for the present. The export trade in finished iron and steel has declined to very small proportions, the shipments of the past week comprising machinery worth £1100, steel goods £3860, and iron goods £3436.

The coal trade is in a very unsatisfactory state owing to the strike, the exports from Scottish ports during the week amounting in the aggregate to only 23,970 tons, compared with 170,680 in the corresponding week. A large number of vessels arrived in the Clyde bringing cargoes of coal from different parts of England, and these are being sold at prices which are considered moderate in the circumstances.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

Two more bodies have been brought up from the Albion, making a total of 290. The colliery is now in full work again. Few places have been more visited by the tourist, pedestrian, or bicyclist, than this colliery since the explosion, and even now interest has not flagged, and it is being suggested that in aid of the widows and orphans a collecting box by the wayside shall be placed. One outcome of the disaster is a stimulus to the inventive. Various ingenious arrangements in connection with colliers' lamps are being devised. That of Mr. D. Evans, of Merthyr, now patented, takes a prominent place, in totally preventing a lock being opened by an addition to the plug method. Another, by Mr. Hawkins, aims to further secure the lock with melted lead, which can only be removed by passing an electric current over it. In addition to these there is the watering tram for wetting coal dust, invented by Messrs. H. W. Lewis and H. Kirkhouse. The latter gentleman is also inventor of the "Harbour of Refuge," which has only, I believe, been put into practical working at Tyler's Town. The idea of the inventor was to make the lamp station of collieries a harbour, into which—on the occasion of an explosion—all could make their way, and with appliances provided for escape from the after-damp. I have heard the plan spoken of favourably by leading authorities. The objection is, in one quarter, that it might be wrecked by an explosion, and in another the expense and trouble.

In this column I, many years ago, referred to the invention of a working collier, who devised a helmet with a receptacle for water and a covering for the mouth. At one of the Gethin accidents a man escaped by wetting his cap with cold tea and holding this to his mouth, breathing through the wet cloth. This was the idea worked upon by the designer of the helmet. One of the sufferers at the Albion tried the same preventive, but it failed, as he was found dying with blood over his mouth and nostrils and the wet cap in his hand.

The holiday influences over the week have been unmistakeable, works half employed, collieries in part idle, offices at the docks closed for half the week. Such have been the prominent features, though no one doubts a fair resumption of business by next week at collieries and docks. In respect to the ironworks the slackness prevailing in the tin-plate district is reacting badly upon the iron and steel works, and the falling off in steel bar requirements is very noticeable in the matter of rails. The only two cargoes sent away this week have been small ones for Highbridge and Bristol. Small parcels continue to be the rule, and with it a blending of "small goods." In pig the stocks held are large, and still a considerable import continues from the North of England. Last week large quantities of pig and steel bar came to Swansea by sea.

Coal prices are tolerably firm. On 'Change and amongst leading shippers it is fully expected that an upward tendency will be shown after the holidays. The latest quotations, Cardiff, for best steam, are 11s. 9d. to 12s.; seconds, 11s. to 11s. 6d.; best Monmouthshire, 10s. to 10s. 6d.; seconds, 9s. 6d. to 9s. 9d.; good dry coal, 10s. to 10s. 3d.; small, 5s. 3d. to 5s. 6d.

House coal has kept up well, in part owing to the unseasonable summer. Latest Cardiff prices are:—Best, 12s. to 13s.; seconds, 10s. 9d. to 11s.; No. 3 Rhondda, 10s. 6d. to 10s. 9d.; brush, 8s. 9d.; small, 6s. 9d. to 7s.; No. 2 Rhondda, 9s. 6d. to 10s.; through, 7s. to 7s. 3d.; small, 5s. Coke prices are maintained: furnace, at 15s. to 16s. 6d.; foundry, 17s. to 17s. 6d., and special foundry, 20s. to 20s. 6d. In the matter of house coal the opinion on 'Change, Cardiff, is that a brisk autumn season is certain. Bookings forward are becoming larger, and the tendency to book freely when prices are moderately low is generally taken to be significant of large autumnal contracts. This hint to buyers is very clear. The output in Glamorgan and Monmouthshire of excellent house coals is unquestionable. I see that a good old house coal, the Lantwit, is being again worked, and the area of No. 3 Rhondda and of the Mynydislwyn is yet large. Troubles continue to beset the Dowlais-Cardiff colliery in the shape of water, but I hear that coal has been struck in one of the pits.

Shipments of coal from Cardiff, Swansea, and Newport last week were large. Swansea total was 44,000 tons; Newport was considerable, both for foreign shipment and coastwise. In patent fuel Swansea maintained a brisk export, Russia taking 3000 tons, Italy 3000, and France 3120 tons.

Iron ore prices are unaltered, demand slackening. Iron and steel quotations unchanged.

In the tin-plate trade the outlook is not so gloomy as last week, and on 'Change, Swansea, mid-week, it was stated that a compromise between the two parties in America having been arrived at, the Tariff Bill is certain to pass. This has given substantial hopes in the coming of better times, if the turbulence of workmen can be modified. Arrangements, I am happy to learn, have been brought about in some quarters, and, apparently, binding arrangements formed. It is remarkable that a sliding scale, similar in excellence to that of the Coalowners' Association, cannot be fashioned, and the tendency to strike amongst tin-platers be checked by leading and intelligent representatives from amongst themselves. In their best interests this should be done.

Last week there was a larger shipment than ordinary of plates from Swansea; 68,356 boxes; quantity received from works, 63,177. Prices the same, but immediately on favourable news from America, which is expected to come in the form of a boom, prices must go up. Britain Ferry Works continue well employed. Sixteen mills are now in action, and the output of steel bars and pig is a good average.

The Swansea and Ilfracombe Steamship Alexandra Company has been registered, with a capital of £10,000 in £5 shares.

Shipping news at Cardiff is unsatisfactory, freights being so low. The freights from Cardiff to Alexandria are about 4s. 3d., and Genoa only 4s. 9d. to 5s., which is 1s. 6d. to 2s. less than prices ruling a few months ago. Shipowners are complaining bitterly that it is impossible to make any margin of profit, and cases of even serious loss have occurred, rendering it less expensive to lay steamers up than to run them. One great failure is announced.

The half-yearly meeting of the Taff Vale Railway shareholders has been held at Bristol under the presidency of Mr. Arthur Guest, and at the close of a long and interesting report, which gave an excellent insight into the company's doings and prospects, a dividend of 3½ per cent. was declared, equal to 8½ per cent. on the old ordinary stock.

A highly complimentary reference was made to the general manager, whose efforts in all ways have been able and energetic, and the suggestion was cheered that pitwood should be imported *viâ* Penarth Dock, and the railway income be increased thereby.

Unrest amongst some sections of the working men continues. This week it is the boilermakers at Barry Dock. Messrs. R. Stevenson and Co., of Newcastle-on-Tyne, are the contractors for the erection of the gates at the deep lock works, Barry Dock, and it is amongst these that a ferment has arisen, the union men refusing to go to work until the contractor gives an undertaking not to employ non-society men.

A Newport inventor has constructed a water cycle, which is to be tried forthwith on the Bristol Channel.

The attainment of majority by the heir of Lord Wimborne has led to the fullest demonstration in the district, and local newspapers have teemed with the annals of the Guest family, the usual humble uprise, and their magnificent achievements. These are all more or less summaries, or quotations from "The Guest Annals," which appeared twenty years ago in the "History of Merthyr," and are to form a feature of the "History of the Iron Trade of Wales," now in compilation and dedicated, I am pleased to hear, by special permission to Lord Wimborne.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

ONLY a moderate amount of business has been done in the different branches of the iron industry this week, but as producers are generally fairly well situated for contracts, they have been able to firmly maintain their prices, and the tone of the market may be described as satisfactory.

There is little or no change noticeable in the Silesian iron trade since previous letters; orders for pig iron are few, as well on home as on foreign account, and the tendency of prices is, naturally, rather weak. Manufactured iron makers, as a rule, report this branch of trade as in a fairly good condition, a number of small orders having come in lately, so that, for the present, the mills are generally pretty well off for work. Quotations do not show any appreciable change upon the week.

In Austria-Hungary makers, as well as dealers, report themselves fairly well content with the present state of the iron market, though pig iron is rather weak in tone and consumption remains but limited. But there is quite an active business done in most sorts of manufactured iron, girders, for instance, and general structural material being briskly called for, while the demand coming in for bars and plates, though a fairly regular one, is not very lively at the present moment, autumn business having not yet commenced. Shipbuilders and engineers are very busy, several good repair jobs having come to hand, which will engage attention for some time to come, and there are more orders for bridges, &c., holding out, so that a vigorous activity is likely to be maintained in that department.

All through last week a quiet sort of business has been done on the French iron market, only in the Department Nord the demand for bars and plates has shown increasing animation. The forges are, as a rule, satisfactorily occupied, and prices have hitherto been firmly maintained. In the steel trade not much has been doing lately, and some establishments complain of being but very insufficiently employed.

On the Belgian iron market only a very small amount of business is still being put through. Pig iron continues weak in demand generally; owing to unceasing efforts on the part of the blast furnace works, foreign trade in crude iron has been a trifle more animated of late. The business in manufactured iron is very quiet all round, the general demand not only on home but also on foreign account remaining exceedingly dull. Heavy plates are the only article that has been rather well inquired for upon the week. The condition of prices is pretty firm.

The Rhenish-Westphalian iron market has, on the whole, maintained the appearance of former weeks, most sorts of pig iron being in good demand, while the different articles of finished iron also meet with a regular though not very brisk inquiry, and prices are all the more firmly maintained because a fair autumn business is generally anticipated. With the exception that perhaps here and there a temporary relaxation in the pressure of demand has been noticeable, the position of the iron ore trade continues very much as previously reported. Quotations are, for spathose iron ore, M. 7·40 to 7·90 p.t., roasted ditto being paid with M. 11 to 11·50 p.t. net at mines. For inferior sorts M. 9·80 to 10 per cent. is given. Minette of Lorraine has well maintained the old price of M. 2·50 to 3·20 p.t. at mines. In the pig iron business demand has been just a trifle more quiet this week than last, but prices are very fairly maintained. Spiegeleisen, which continues to be quoted M. 52 p.t. is in fair request on foreign account, but home demand has been comparatively poor. Forge pig No. 1 costs M. 46 p.t.; No. 3, M. 40 p.t.; Siegerland good forge quality, M. 44 p.t.; hematite, M. 63 p.t.; foundry No. 1, M. 63 p.t.; No. 2, M. 54 p.t.; basic, M. 45 p.t.; German Bessemer, M. 49 to 50 p.t. Luxemburg forge pig continues to be quoted 48f. p.t., free Luxemburg. The tone of the malleable iron market may be termed a satisfactory one, considering the time of the year, and there have even been symptoms of an improvement in demand since last week. The bar trade is, all things considered, in a fairly good condition, the mills being tolerably well engaged on inland and foreign orders, and there is a pretty firm tendency maintained in quotations. The South German bar mills have even ventured to raise their prices M. 3 p.t. In girders a moderate business is done, while hoops present no change whatever since former reports, being in fair request at moderate prices. A satisfactory employment is maintained at the plate and sheet mills, and orders, as well as inquiries, come in quite regularly, so that makers might be fairly content with the present state of affairs, if prices were a trifle less unremunerative. The demand for drawn wire continues regular, foreign inquiry having been really good, especially that from North America. Rivets meet with an increasing request, but prices continue low, the cutting competition of foreign houses leaving but little chance for an improvement in quotations. The wagon factories are likely to be in brisk employment for some time to come, having secured orders for 1000 covered and 1000 open cars, 1300 coke wagons, 450 small cars and appurtenances, which have recently been given out by the Government railways.

Latest list prices per ton at works are as under:—Good merchant bars, M. 110; angles, M. 120; girders, M. 90 to 95; hoops, M. 113 to 118; billets in basic and Bessemer, M. 81; heavy plates for boilermaking purposes, M. 150; tank ditto, M. 130 to 135; steel plates, M. 125; tank ditto, M. 115 to 120; sheets, M. 140; Siegen thin sheets, M. 130; iron wire rods, common quality, M. 115 to 120; drawn wire in iron or steel, M. 105 to 120; wire nails, M. 125; rivets, M. 150 to 155; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 115; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230; light section rails, M. 95.

The Chinese Government is reported to have ordered four torpedo boats from German houses.

## IRON AND STEEL INSTITUTE—BRUSSELS MEETING.

THE autumn meeting of the Iron and Steel Institute will be held at Brussels, and will commence on Monday, August 20th. The following papers have been offered for reading:—

"On the Use of Caustic Lime in the Blast Furnace." By Sir Lowthian Bell, Bart, F.R.S., past-president.

"On the History of Crucible Steel." By R. A. Hadfield, member of Council.

"On the Coal-mining Industry of Belgium." By A. Briart, President of the Society of Engineers of Hainaut.

"On the Iron and Steel Industries of Belgium." By A. Gillon, President of the Society of Engineers of Liége.

"On the Influence of Aluminium upon the Carbon in Ferro-carbon Alloys." By T. W. Hogg—Newburn Steel Works.

"On some Properties of Boron Steel." By H. C. Jenkins—Royal School of Mines.

"On Colour-gauges for Carbon Determination." By W. G. McMillan—Mason College.

"On Electrical Power in Belgian Ironworks." By D. Selby-Bigge.

"On the Manufacture of Coke." By the late R. de Soldenhoff.

The following outline programme has just been published:—

Monday, August 20th: The Secretaries' office will be open from 2 p.m to 6 p.m. in the Bourse, Brussels, for the registration of addresses, issue of programmes, &c. Members' correspondence may, conveniently, be addressed Poste Restante, Brussels, as the post-office is situated in the Place de la Monnaie, close to the Bourse. 5.35 p.m.—Arrival of the train from Ostend. 8.30 p.m.—Conversazione and reception in the Hotel de Ville—Town Hall—by the Civic Authorities—evening dress.

Tuesday, August 21st: 9 a.m.—Secretaries' office open in the Bourse. Meeting of Council. 10 a.m.—Reception of the President, Council, and Members of the Institute, by Mr. A. Gillon, the chairman, Mr. A. Briart, the vice-chairman, and the members of the reception committee. Reading and discussion of papers. The afternoon will be devoted to visiting the Antwerp International Exhibition.

Wednesday, August 22nd: The morning will be devoted to the reading and discussion of papers, and the afternoon to visiting places of interest in Brussels.

Thursday, August 23rd: The members will leave Brussels by special train to visit the Mariemont Collieries and the Couillet Steel Works at Charleroi, returning to Brussels in the evening.

Friday, August 24th: The members will leave Brussels by special train to visit the works of the Cockerill Company at Seraing and the Angleur Steel Works at Liége, returning to Brussels in the evening.

## AMERICAN NOTES.

*(From our own Correspondent.)*

New York, August 3rd.

The abundance of money in the banks of Eastern cities and at Chicago shows the extent of abnormal conditions in trade and manufacturing. No improvement except in retail circles is felt. Inquiries are increasing for rails and all kinds of crude and finished iron. An increased activity is promised in locomotive, car, and bridge works. Several merchant iron mills started last Monday. Steel billets are in very active demand, and, if makers could promise deliveries, works could be filled up at once for two months. The coke strike is no nearer settlement. No. 1 foundry is offered at 12 dols., mill irons at 10·50 dols., steel rails 24 dols. New work is in sight. Coal mining is interrupted by strikes at various points. Western Pennsylvania controls the cream of the iron trade. Ohio mills are awaiting promised fuel. The financial outlook is not assuring, and another issue of Government bonds is looked for in banking circles, because of the declining revenues. Gold mining is steadily increasing, and there is some improvement in silver production.

## LAUNCHES AND TRIAL TRIPS.

The s.s. Bangor went down the Clyde for official trial, and on the measured mile attained a speed of 12 knots. The principal dimensions are:—145 by 24 by 11 moulded; engines, 20in. and 40in. by 27in., 100-horse power. Built by Messrs. Scott and Sons, Bowling; engined by Messrs. Ross and Duncan, Govan. Steamer is specially designed to carry slates from Bangor, North Wales, to Aberdeen, has a deadweight capacity of 400 tons, and a net register of 91 tons. Fitted with steam direct windlass, self-stowing anchors, steam steering gear, and patent warping winches, and every modern improvement for quick loading and discharging in this special trade. MacColl's patent stern-tube is fitted, which appears to solve the difficulty of corroded propeller shafts, and avoids the expense and delay of re-wooding stern bush. The owners' representative, Mr. O. T. Jones, expressed pleasure at the fine finish and general utility of space. Vessel and machinery were constructed under the superintendence of Mr. James Maxton, of Belfast.

## ON SULPHUR IN CAST IRON.*

By W. J. Keep.

The author has for six years been trying to verify the received belief that sulphur is in every way injurious to cast iron, and has made numerous experiments with artificially sulphurised cast iron up to 2 per cent. of sulphur, both grey and white, the results of which are recorded in the paper. The conclusion finally reached is that the proportion of sulphur retained by grey cast iron cannot materially injure the iron except by increase in shrinkage, which in the extreme ends seems to be from 0·168in. to 0·194in. per foot. The general testimony is that most of the sulphur present in pig iron is lost in re-melting, and that it is impossible that it can be re-absorbed to any damaging extent from the fuel. The influence of sulphur is diminished by increase of carbon or silicon. In wrought iron, which is practically free from these elements, a small amount of sulphur is said to do great harm, and such iron will take up sulphur in considerable quantity. In steel containing less than 1 per cent. of carbon and practically no silicon a few hundredths per cent. of sulphur cause decided injury. With carbon increases to saturation as in white cast iron, not more than 0·50 per cent. of sulphur can be retained, and as silicon increases, producing graphitic carbon, it is still more difficult to find sulphur in the metal, as it will not absorb it from the outside.

The influence of sulphur on all cast iron is to drive out carbon and silicon, to increase shrinkage, and in general to reduce strength, but in practice sulphur will not enter the iron in the foundry to a sufficient extent to realise these defects. When, as happens sometimes, iron which was grey when put into the cupola comes out white with increased shrinkage and chill, and often with decreased strength, the change is due to loss of silicon, and can be remedied by remelting with an appropriate addition of ferro-silicon or other highly silicised metal.

That highly sulphurised iron cannot be produced in practice is evident from the fact that ores are used—in America—containing over 3 per cent. of sulphur with fuel containing nearly 1 per cent. of the same element; but all smelters are agreed that not more than 0·75 per cent. of sulphur can be found in white iron, 0·25 per cent. in mottled, and not more than a few hundredths in grey foundry iron. The experiments show that 0·50 per cent. of sulphur will not exert any appreciable deleterious influence, and even that may be at once corrected by a slight increase in silicon.

Remembering that the only noticeable effects would be to slightly increase the shrinkage, the above conclusion seems to be proved by the fact that, in a foundry working with a substantially uniform mixture, returning from 25 to 40 per cent. of its metal to the cupola to be re-melted over and over again each day, the castings will almost invariably have a less shrinkage than the average of the pig iron used, and yet they will probably contain more sulphur and less silicon than the pig iron originally did.

The depth of chill does not seem to be influenced by these small proportions of sulphur, neither is there any evidence to show a relation between sulphur contents and strength either in pig iron or ordinary castings. The author hopes at a future time to explain why inferior castings are from time to time produced from a uniform mixture of pig iron.

Health Exhibition at Boulogne.—An International Health Exhibition, under the patronage of the Minister of the Interior, has been opened at Boulogne. There is an interesting and extensive collection of sanitary and hygienic appliances of all kinds.

## THE PATENT JOURNAL.

14,364. Pneumatic Tires, D. Doig, London.
14,365. Apparatus for Cutting Fruit, R. Machin, London.
14,366. Gloves Used in Football, &c., F. Bryan, London.
14,367. Oil Stoves, S. Falk, London.
14,368. Book Slides, G. Sims, London.
14,369. Storing and Packing Opium, A. Castenholz, London.
14,370. Golf Balls, H. B. Sleeman.—(*R. N. Coghlan, India.*)
14,371. Fire-alarm Telegraphs, G. R. Neilson and A. C. Brown, London.
14,372. Elliptical Driving Gear, A. J. Boult.—(*E. Barabraham, France.*)
14,373. Metallic Packing for Piston-rods, E. Cunningham, Liverpool.
14,374. Bleaching Textile Fabrics, B. Walsh, Manchester.
14,375. Vulcanising Water-proof Garments, I. Frankenburg, Manchester.
14,376. Photographic Printing Frames, C. A. McEvoy, London.
14,377. Holding Devices, H. W. Poole and H. M. Knight, London.
14,378. Tethering Apparatus for Horses, A. J. Instone, Surrey.
14,379. Movable Reading Stand for Fixing to Tables, A. E. Smith, London.
14,380. Mechanical Musical Instrument, F. A. Richter, London.
14,381. Water Purifier, A. Golinski and H. Lambion, London.
14,382. Centrifugal Pump Delivery Tubes, P. Hövig, London.
14,383. Weft Forks, E. Birley and T. Duxbury, London.
14,384. Manufacture of Parchment, H. O. Band, London.
14,385. Gas Engines, J. A. McMullen, London.
14,386. Textile Fabrics, M. Schwartz, London.
14,387. Laundry Iron, F. W. Dover, London.
14,388. Tobacco Pipes, J. Notton, London.
14,389. Armour Plates, H. H. Lake.—(*Harvey Steel Company, United States.*)
14,390. Storing Petroleum, T. G. B. de Ferrari, London.
14,391. Preventing Incrustations on Boiler Plates, La Société Chaligny et Cie., London.
14,392. Engine Stopping Apparatus, L. C. E. Meyer, London.
14,393. Candlesticks, O. C. Uber and C. G. Uber, London.
14,394. Induction Coil Apparatus, H. J. Dale, London.
14,395. Lamp Wicks or Burners, A. J. Aitkens.—(*G. Aitkens, New Zealand.*)
14,396. Letter-boxes, A. C. Turner, London.
14,397. Coal-dust Feeder for Furnaces, A. Friedberg, London.
14,398. Envelopes, S. Whybrew, Philadelphia, U.S.A.
14,399. Rail Straightening Implement, A. Meuser, Philadelphia, U.S.A.
14,400. Heaters and Tables, E. M. Burchard, Philadelphia, U.S.A.
14,401. Calculating Machines, J. A. Sewell, Philadelphia, U.S.A.
14,402. Flexible Belt Fender, R. B. Chambers, Philadelphia, U.S.A.
14,403. Journal Bearings, W. J. and J. J. Carter, Philadelphia, U.S.A.
14,404. Cloth Measuring Machine, I. E. V. Duzer and H. Vanderburgh, Canada.

*27th July*, 1894.

14,405. Fishing Rods, W. H. Foster, Derbyshire.
14,406. Buttons, T. R. Wing, London.
14,407. Varnishes, D. Marcus, London.
14,408. School Desks, F. H. Fisher, Birmingham.
14,409. Cycle Bells, J. Harrison, Birmingham.
14,410. Globe Holders, H. Halliday and G. H. Barnes, Birmingham.
14,411. Circular and Letter Forms, D. H. Irwin, Cheshire.
14,412. Cycle Gear, C. W. Holmes and S. Beech, London.
14,413. Coal-saving Devices, E. W. Banner, Liverpool.
14,414. Holder for Painting Golf Balls, D. D. Macpherson, Manchester.
14,415. Lubricating Piston-rods, T. Mudd and J. Airey, Liverpool.
14,416. Railway Gates, E. Currier, London.
14,417. Guard for Carving Forks, J. Wigfall, Sheffield.
14,418. Garment Retainers, W. M. Harris, Birmingham.
14,419. Traps and Syphons, J. Merrill, Sheffield.
14,420. Adjustable Rails, W. Whiting and H. B. Tucker, Bath.
14,421. Pickers for Looms, J. Muir and A. Muir, Glasgow.
14,422. Bobbin Wheel Protectors for Slubbing Frames, J. W. Stubbs, Manchester.
14,423. Air Compressing, &c., Engines, J. Wild, Manchester.
14,424. Holding Labels to the Sides of Vehicles, T. Mills, Halifax.
14,425. Gas Engine, C. R. Roberts, Dorset.
14,426. Manufacture of Knurs, W. Sykes, Yorkshire.
14,427. Preventing Children Falling into Dolly Tubs, W. Needham, London.
14,428. Controlling Loom Shuttle Boxes, A. Lockwood, Keighley.
14,429. Valve Gear of Combustion Engines, W. H. Pasley, Dorset.
14,430. Valves for Air Regenerators, W. W. Pilkington, Liverpool.
14,431. Gas Generators, &c., W. W. Pilkington, Liverpool.
14,432. Compound Locomotives, F. W. Webb, Crewe.
14,433. Manufacturing a Compote from Jelly, P. A. Noll, Berlin.
14,434. Instrument for Piercing the Human Ear, D. Willman, Dublin.
14,435. Pencils for Writing, &c., W. A. Thornton, Leeds.
14,436. Incombustible Burners for Liquid Fuel, C. Westphal, Liverpool.
14,437. Apparatus for Collecting Household Refuse, S. L. Kinsbruner, Liverpool.
14,438. Sewing Machine Shuttles, A. Anderson.—(*The Singer Manufacturing Company, United States.*)
14,439. Sewing Machines, A. Anderson.—(*The Singer Manufacturing Company, United States.*)
14,440. Spring Driving Mechanism, P. Lochmann, London.
14,441. Brake and Foot Rest for Cycles, C. H. Flint, Birmingham.
14,442. Grass Border Protectors, J. N. Lester, Wolverhampton.
14,443. Wire for Lawn Tennis Racket, C. Burrows, Cumberland.
14,444. Preparing Wheat, J. T. O'Callaghan, London.
14,445. Electric Railways, J. Y. Johnson.—(*Malone Wheless, United.*)
14,446. Apparatus for Enlarging and Reducing Photographic Negatives, C. S. Jones, Essex.
14,447. Preventing Waste of Beer, G. S. Trafford, London.
14,448. Surgical Drainage Tube, A. Essinger.—(*Paul Hartmann, Germany.*)
14,449. Navigable Balloons, &c., J. B. Scammell, London.
14,450. Wick and Case, G. Aitkens and J. A. Pike, Birmingham.
14,451. Cocoa-pot and Agitator, &c., C. M. Blagdon, London.
14,452. Cameras, G. Dixon, Edinburgh.
14,453. Arithmetical Instrument, G. Thomson, Edinburgh.
14,454. Trace Springs, H. R. Kirschbaum.—(*W. Kirschbaum and Co., Germany.*)
14,455. Lightship Connections, E. Templeton and H. P. Schisckar, London.
14,456. Solitaires, T. Morton, Birmingham.
14,457. Vapour Burners and Torches, C. Thompson, London.
14,458. Holders for the Bottles of Milk-testing Machines, S. Cheeld, London.
14,459. Printing Machinery, M. M. Spear, London.
14,460. Surveying by Photography, J. B. Lee, London.
14,461. Chemical Dyes, G. W. Johnson.—(*Kalle and Co., Germany.*)
14,462. Detachable Gear for Boats, F. A. Rodewald, London.
14,463. Boats' Tillers, F. A. Rodewald, London.
14,464. Safety Locking Bars for Points, C. Hodgson, London.
14,465. Dresses, Bodices, and Jackets, T. Jones, Manchester.
14,466. Gearing for Bicycles and Vehicles, T. Ellis, London.
14,467. Quoins or Wedges for Mining, A. François, London.
14,468. Mountings for Quick-fire Guns, A. H. Bogle, London.
14,469. Portable and other Cranes, H. Sadler, London.
14,470. Raising and Drawing Liquids, A. Bonnoront, London.
14,471. Tobacco Pipes, G. G. Kerr and J. L. Kerr, London.
14,472. Photographic Hand Cameras, S. C. Rudman, London.
14,473. Sliver Cans and Driving Mechanism, G. Meyer, London.
14,474. Loom Shedding, E. B. Redmayne and R. Pickles, London.
14,475. Safety Device for Workmen, J. Marawske, London.
14,476. Vapour or Gas Motor Engine, C. H. Bryant, London.
14,477. Device for Holding Umbrellas, A. Stone, London.
14,478. Camp Stool and Walking-stick, N. and J. Bouvet, London.
14,479. Ranges, &c., J. Slater and C. E. Hauvette, London.
14,480. Transmitters for Sewing Machines, J. White, London.
14,481. Tungsten Articles and Apparatus, A. Meig, London.
14,482. Attaching and Fixing Balusters, A. S. Cripps, London.
14,483. Wire Tray for Biscuit Bakers, J. Hillman, London.
14,484. Case for Thermometers, C. M. Page, London.
14,485. Harrows, J. Gerth and A. Schwarzenberg, London.
14,486. Support for Water Bottles, B. S. Phillips, London.
14,487. Gas Engines, D. Clerk, London.
14,488. Electric Arc Lamps, J. Jeffryes and J. Lea, London.

*28th July*, 1894.

14,489. Aprons, P. R. J. Willis, London.
14,490. Pneumatic Tyres, W. L'Estrange, Manchester.
14,491. Teaching Model Drawing, F. D. King, Bradford.
14,492. Reflector for Photographers' Lamps, A. G. Adamson, Glasgow.
14,493. Electric Light for Photographers' Lamps, A. G. Adamson, Glasgow.
14,494. Slag for the Manufacture of Cement, W. Thomlinson, Stockton-on Tees.
14,495. Means for Roasting Grain, A. Perry, London.
14,496. Manufacture of Iron, C. J. Sandahl, Liverpool.
14,497. Penholders, W. J. Thornhill, Manchester.
14,498. Preventing the Bagging of Trousers, W. Cooke, Liverpool.
14,499. Safety-valves for Hot-water Boilers, J. Edge and T. P. Richards, Liverpool.
14,500. Wheels for Vehicles, J. Jordan, London.
14,501. Emery Wheels and Grindstones, A. A. Tattersall, Glasgow.
14,502. Metallic Alloy, J. W. Dixon and W. Skinner, Sheffield.
14,503. Recovering Hydro-cyanic Acid from Mixtures, G. T. Beilby, Slateford, N.B.
14,504. Valves for Steam Engines, J. Cochrane and W. Cameron, Barrhead, N.B.
14,505. Feeding Printing Machines, J. J. Allen, Halifax.
14,506. Spindles, S. Williams, Halifax.
14,507. Rods for Spring Blind Rollers, J. Robertshaw, Manchester.
14,508. Sash Pulleys, P. Daw, Birmingham.
14,509. Electric Current Regulators, H. V. Keeson, London.
14,510. Hinge Lock and Sash Fastener, D. Griffin, Birmingham.
14,511. Drawing Frames, R. Hartley and J. B. Cocks, Rochdale.
14,512. Hammocks, Lounges, and the like, N. Voice, Sussex.
14,513. Refrigerator Separator, C. Johnson, Scarborough.
14,514. Damping Seams, D. Römhildt, Germany.
14,515. Bowls of Tobacco Pipes, R. Heyd, Germany.
14,516. Clocks, A. J. Treadaway and W. Collins, Birmingham.
14,517. Children's Mail-carts, H. I. Humphry, Birmingham.
14,518. Telephone Switchboard Apparatus, A. Whalley, Warrington.
14,519. Machine for Sorting Cereals, F. H. Schule, Glasgow.
14,520. Producing Nitric Acid Free of Halogen and Nitrose, W. B. Maxfield.—(*W. Dieterle and L. Rohrmann, Germany.*)
14,521. Buttons, C. Heaton and Co. and H. Heaton, London.
14,522. Removable Coverings for Tramcars, F. Brangwin, London.
14,523. Mechanical Toy Bells or Gongs, O. Hanks, London.
14,524. Castors for Furniture, E. Pratt, London.
14,525. Setting Types and Signs for Photos, E. Porsolt, London.
14,526. Sewing Machines, I. Nasch and W. Nasch, London.
14,527. Gates, W. J. Slack, London.
14,528. Ironing Board for Tables, &c., H. S. Grant, London.
14,529. Governors or Steam Motors, C. G. P. de Laval, London.
14,530. Apparatus for Emptying Cesspools, J. Watts, London.
14,531. Regulating Feed-water Supply to Boilers, J. E. L. Ogden, H. B. Watson, and J. S. Watson, London.
14,532. Projectiles for Ordnance, &c., T. Turner, London.
14,533. Transforming Electric Currents, J. Fleming, London.
14,534. Carcase Stretcher, A. J. Boult.—(*J. E. Perl, United States.*)
14,535. Lead Seals, C. Herfort, Liverpool.
14,536. Electric Welding, C. F. Parkinson and W. Gatwood, Manchester.
14,537. Pockets for Painters' Jackets, W. W. Peck, Liverpool.
14,538. Fastening Device for Window Sashes, H. Hook, Liverpool.
14,539. Combs, L. Auerbach, London.
14,540. Braces, &c., T. Roghmanns and C. Richter, London.
14,541. Closets, W. Krebs, London.
14,542. Filter, S. Stroh, London.
14,543. Cooking Cage, E. M. Seed, London.
14,544. Utilising Exhaust from Engines, F. W. Golby.—(*J. M. Salaud, France.*)
14,545. Electromotors, T. Parker, Ld., and T. Parker, London.
14,546. Electric Contact by Weight, S. David, London.
14,547. Treating Gold and Silver Ores, E. L. Mayer, London.
14,548. Checking and Indicating Money, T. S. Howie, London.
14,549. Wrenches and Pipe Cutters, J. Manning, London.
14,550. Steam Engines, H. Grafton, London.
14,551. Transmission of Signals, D. Young.—(*J. M. McMahan, United States.*)
14,552. Bottle, R. S. Trueman and J. C. Trueman, London.
14,553. Refractory Retorts, N. Teissier and G. L. A. Nègre, London.
14,554. Heating and Cooling Liquids, A. Lawrence and Bennett, Sons, and Shears, Ld., London.
14,555. Preserving Perishable Goods, W. S. Simpson, London.
14,556. Forging Metals, H. H. Lake.—(*A. B. Ibbotson, Italy.*)
14,557. Ball Bearings, R. F. Hall, London.
14,558. Appliance for Use in Massage Treatment, W. T. Cormick, London.
14,559. Horseshoes, W. Q. Botten and H. Morel, London.
14,560. Locking Devices for Velocipedes, H. H. Lake.—(*O. Schröder, Denmark.*)
14,561. Ventilators, E. J. How and H. King, London.
14,562. Billiard Checkers, F. W. Heaton, Manchester.

*30th July*, 1894.

14,563. Pumps for Pneumatic Tires, J. P. Titterton, London.
14,564. Drawing Instrument, G. R. Postlethwaite, Birmingham.
14,565. Dyeing Hat Bodies, J. Booth and L. Thornley, Manchester.
14,566. Reversing the Pitch of Propellers, A. V. Coster, Hull.
14,567. Hearths for Boilermakers, &c., J. A. Riley, Halifax.
14,568. Hardening Wire, J. H. Roberts and J. Cooper, jun., Bradford.
14,569. Tubulous Steam Generators, B. H. Thwaite, London.
14,570. Automatic Electric Contact, G. Hussey, Clitheroe.
14,571. Buckle for Fastening Belts, C. C. Walker, Walsall.

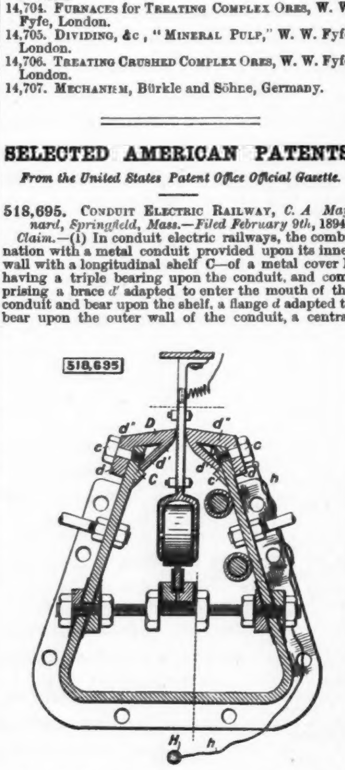
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**518,695.** Conduit Electric Railway, *C. A. Maynard, Springfield, Mass.—Filed February 9th*, 1894.

*Claim.*—(1) In conduit electric railways, the combination with a metal conduit provided upon its inner wall with a longitudinal shelf C—of a metal cover D having a triple bearing upon the conduit, and comprising a brace *d'* adapted to enter the mouth of the conduit and bear upon the shelf, a flange *d* adapted to bear upon the outer wall of the conduit, a central portion *d''* integral with the brace and flange and adapted to be seated upon a top rim of the conduit, and screw bolts *c* through flange *d* and the wall of the conduit, as and for the purpose set forth. (2) In conduit electric railways, the combination with a return wire H removed from the conduit, and with removable covers D D, of auxiliary wires *h* arranged to connect the two, as and for the purpose set forth.

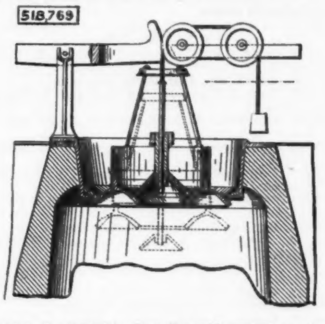
518,695



**518,769.** Charging Apparatus for Filling Blast Furnaces, *T. F. Witherbee, Port Henry, N.Y.—Filed June 27th*, 1893.

*Claim*—(1) A charging apparatus for blast furnaces, which comprises an annular movable bell having a central aperture, the spreading bell, I, which is of less diameter than said aperture and thereby adapted to pass through it so as to occupy a position either above or below the annular bell, and means for raising and lowering the said spreading bell, as shown and described. (2) A charging apparatus for filling blast furnaces, comprising a movable bell having a central aperture, and a spreading bell adapted to pass through the said central aperture below the said movable bell and centrally thereof, and a fixed bell adapted to close the said central aperture of the movable bell and also adapted to receive the said spreading bell, substantially as shown and described. (3) A charging apparatus for blast furnaces, which comprises an annular bell arranged within a hopper, and having a vertical, circular extension, E, constituting a supplemental inner hopper, a bell for closing such inner hopper, and means for raising and lowering the annular bell and its hopper, as and for the purpose specified. (4) A charging apparatus for filling blast furnaces, comprising a hopper secured to the stack of the blast furnace, an annular movable bell adapted to be seated on the contracted end of the said hopper, the said movable bell having a central aperture, a second hopper secured on the crest of the said movable bell, a fixed bell adapted to close the said central aperture of the movable bell, and a spreading bell adapted to be seated within the said fixed bell and adapted to pass through the said central aperture of the movable bell, substantially as shown and described.

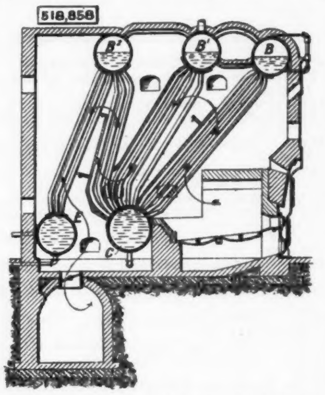
518,769



**518,858.** Steam Boiler. *H. S. Pell, Akron, Ohio.—Filed December 22nd*, 1893.

*Claim*—(1) In a water-tube boiler, the combination of elevated drums having steam and water communication with each other, a lower mud drum, tubes connecting the elevated drums with the lower mud drum, a lower feed drum, tubes connecting the lower feed drum with one of the elevated drums, and means for supplying water to the lower feed drum, substantially as described. (2) In a water-tube boiler, the combination of three elevated steam and water drums, B and $B^1$ and $B^2$, a lower drum C, series of tubes connecting the lower drum with each of the elevated drums, pipes affording steam and water communication between the drums B and $B^1$ and steam communication between the drums $B^1$ and $B^2$, a lower feed-water drum E, a series of tubes connecting the lower feed-water drum E with the elevated steam and water drum $B^2$, and means for supplying water to the lower feed-water drum, substantially as described.

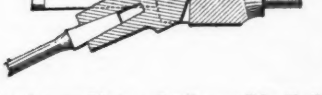
518,858



**518,938.** Bit-stock, *F. J. Colvin, Hamden, Conn.—Filed October 14th*, 1893.

*Claim.*—In a bit-stock, the combination with a head portion, of a block pivoted thereto, and having a socket to receive the head of the bit, and resilient jaws constructed to engage the shank portion of the bit, and expansible in a direction parallel with the axis of the pivot of the block, or in other words, in a direction at right angles to the direction in which the block swings.

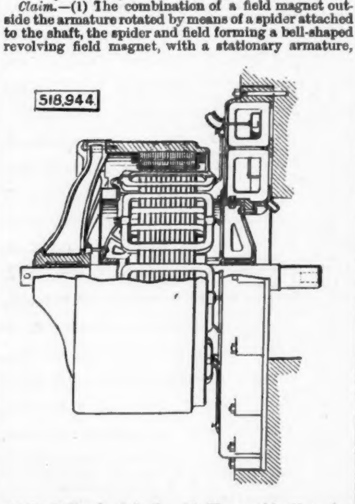
518,938



**518,944.** Dynamo-electric Machine, *G. Forbes, Niagara Falls, N.Y.—Filed August 17th*, 1893.

*Claim.*—(1) The combination of a field magnet outside the armature rotated by means of a spider attached to the shaft, the spider and field forming a bell-shaped revolving field magnet, with a stationary armature, substantially as set forth. (2) The combination of a shaft supported centrally within a stationary armature by brackets attached to the frame of the armature, with a spider and external revolving field, substantially as described.

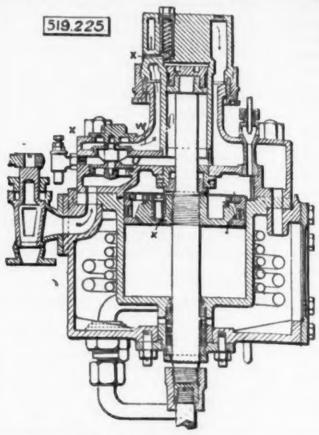
518,944



**519,225.** Pump for Compressing Air or Gases, *G. E. Belliss and A. Morcom, Birmingham, England.—Filed August 1st*, 1893.

*Claim.*—(1) In a gas or air compressor, the low and high-pressure cylinders A G, the pistons B H therein, the air conduit leading directly from one end only of the low-pressure cylinder to the high-pressure cylinder, whereby the air will be forced from the cylinder at one stroke, the cooling tank and passages and the inlet for the water connecting with one of the cylinders, whereby the water will be forced through the cooling passage and tank, subtantially as described. (2) In combination, the low and high-pressure cylinders, the pistons therein, the air conduit from the low to the high-pressure cylinders, the water chamber W around the high-pressure cylinder, the inlet channel U for the water leading to the high-pressure chamber, the valve X opening from the inlet conduit into the chamber W and the water chamber about the low-pressure cylinder connected with the water chamber W, substantially as described.

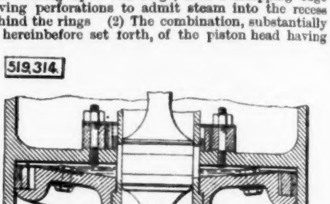
519,225



**519,314.** Metallic Packing, *W. D. Baldwin, Washington, D.C.—Filed June 8th*, 1893.

*Claim.*—(1) The combination, substantially as hereinbefore set forth, of a piston having a groove or recess in its periphery, a series of spring rings mounted in the groove or recess and adapted to press against the working surface of the cylinder, a spring plate secured directly to the piston and having a yielding spring edge overlapping the groove or recess in the piston and bearing upon the rings, said overlapping edge having perforations to admit steam into the recess behind the rings (2) The combination, substantially as hereinbefore set forth, of the piston head having an annular groove or recess in its periphery, the separate overlapping spring rings mounted in the recess and by their own elasticity pressing against the sides of the cylinder, the spring disc or plate secured directly to the piston head and having an outer edge overlapping the recess and bearing directly on the rings, said overlapping edge having perforations communicating with the space in the recess in rear of the rings, the organisation being such that the spring plate is exposed to steam pressure to supplement its elasticity in bearing upon the rings to hold them in place, and the steam pressure admitted through the perforations of the plate supplements the elasticity of the rings to cause them to pack the joint.

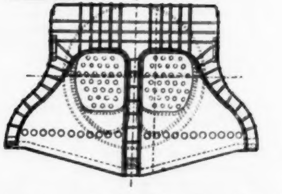
519,314



**519,315.** Locomotive Boiler, *D. L. Barnes, Chicago, Ill.—Filed March 9th*, 1894.

*Claim.*—The combination, in a locomotive boiler, of a laterally extended fire-box, a combustion chamber located within the waist of the boiler at its rear end, a transverse water wall sheet having forwardly-extending flanges at its top, sides, and bottom, and riveted through said flanges to the adjacent sheets of the combustion chamber, and also having rearwardly extending flanges on its top, sides, and at a level above its bottom, a longitudinal water wall forming two separate furnaces in the fire-box, and communicating with the rear water space thereof, front furnace sheets, each having forwardly-extending flanges riveted to the rearward flanges of the transverse water wall sheet, and rearwardly-extending flanges riveted to the side sheets of the longitudinal water wall, and furnace crown and side sheets riveted to rearwardly-extending flanges on the front furnace sheets, substantially as set forth.

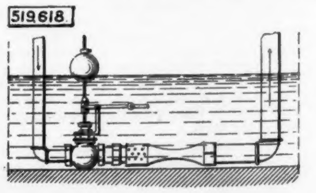
519,315



**519,618.** Fluid Ejector, *N. Power, New York, N.Y.—Filed March 15th*, 1894.

*Claim.*—In an apparatus for draining cellars, the combination, with a pressure pipe, a discharge pipe, and an intermediate ejector, of a balance valve located in the pressure pipe, the valve discs of which are mounted upon a stem, the said stem being connected with a float operating the valve discs, and a counterweight connected with the valve stem, whereby the stem, the parts connected therewith, and the valve discs are counterbalanced, substantially as shown and described.

519,618



## THE BRITISH ASSOCIATION AT OXFORD.

### PRESIDENTIAL ADDRESS—SECTION A.

ON Thursday, August 9th, Professor A. W. Rücker, F.R.S., opened the proceedings at Section A—Mathematical and Physical Science—by delivering his presidential address. He began by speaking of the spread of scientific education in these times, and contrasted it with the position occupied by science in this country in 1860, when the authorities of the Owens College, Manchester, debated whether it was desirable to create a Professorship of Natural Philosophy in addition to, and independent of, the Chair of Mathematics. It was thought necessary to obtain external support for the opinions of those who advocated this step. An appeal was made to Professors de Morgan and Stokes. The former reported that a "course of experimental physics is in itself desirable;" the latter, that "there would be work enough in a large institution for a mathematician and a physicist." In the end, the Chair of Natural Philosophy was established. He also said that the Clarendon Laboratory, in which they were assembled, though erected barely a quarter of a century ago, was the first laboratory in this country which was specially built and designed for the study of experimental physics. It has served as a type. Clerk Maxwell visited it while planning the Cavendish Laboratory, and traces of Professor Clifton's designs can be detected in several of our University Colleges.

After speaking of private munificence as an aid to the advancement of learning, and quoting the example of Sir Henry Thompson, who has offered £5000 to provide Greenwich Observatory with a telescope of 26in. aperture and 22ft. 6in. focal length, also the example of Mr. Ludwig Mond in presenting new research laboratories to the Royal Institution, Professor Rücker said:—"The growth in the number of scientific workers makes it increasingly difficult to find the funds which are necessary for the publication of their work. Up to the present the author of a paper has had to submit it to criticism, but when it has been approved by competent judges, it has been published without ado and without expense to himself. This is as it should be. It is right that due care should be exercised to prune away all unneccessary matter, to reduce as far as may be the necessary cost. It will, however, be a great misfortune if judgment as to what curtailment is necessary is in future passed, not with the object of removing what is really superfluous, but in obedience to the iron rule of poverty. Apart from all other disadvantages, such a course would add to the barriers which are dividing the students of different sciences. A few lines and a rough diagram may suffice to show to experts what has been attempted and what achieved, but there is no paper so difficult to master as that which assumes that the reader starts from the point of vantage which months or years of study have enabled the author to attain. Undue pruning will not make the tree of knowledge more fruitful, and will certainly make it harder to climb. Connected also with the vast increase of scientific literature is a growing necessity for the publication of volumes of abstracts, in which the main results of recent investigations are presented in a concentrated form. English chemists have long been supplied with these by the Chemical Society. The Physical Society, though far less wealthy than its elder sister, has determined to undertake a similar task. We are compelled to begin cautiously, but in January next the first number of a monthly pamphlet will be issued containing abstracts of all the papers which appear in the principal foreign journals of Physics. In this venture the Society will incur grave responsibilities, and I avail myself of this opportunity to appeal to all British physicists to support us in a work, the scope of which will be rapidly extended if our first efforts succeed."

When speaking of the ten years' work of himself and Dr. Thorpe over a minute magnetic survey of the United Kingdom, he made the following remarks about the errors present in certain instruments used in different scientific observatories:—"In the first place, there is little doubt that the instruments at present used for measuring declination and horizontal force are affected with errors far greater than the error of observation. We employed four magnetometers by Elliott Brothers, which were frequently compared with the standard instrument at Kew. These measurements proved that the instrumental differences which affect the accuracy of the declination and horizontal force measurements are from five to ten times as great as the error of a single field observation. The dip circle, which two generations ago was so untrustworthy, is, in our experience, the most satisfactory of the absolute instruments. In most cases these comparisons extended over several days; but the Astronomer Royal has described, in his recent report, observations made at Greenwich, for two years and a-half, with two horizontal force instruments. These differ between themselves, and the discrepancy is of the same order of magnitude as those we have detected. If such differences exist between instruments of the Kew pattern, it is probable that they will be still greater when the magnetometers under investigation are of different types. This point has been investigated by Dr. Van Rijckevorsel, who five years ago visited Kew, Parc St. Maur, Wilhelmshaven, and Utrecht, and using his own instruments at each place, compared the values of the magnetic elements determined by himself with those deduced from the self-registering apparatus of the observatory. The discrepancies between the so-called standards, which were thus brought to light, were quite startling, and prove the necessity for an investigation as to their causes."

He concluded, therefore, that it is necessary that a full primary comparison should be made between the standard magnetic instruments in our different observatories, and that the question would afterwards arise whether it should be repeated at regular intervals.

Much of the rest of the address went deeply into the subject of terrestrial magnetism and its phenomena, and we close this notice by quoting what Professor Rücker said about abnormal magnetic conditions in and around Moscow: "Observations made about thirty years ago by a former director of the Astronomical Observatory in Moscow led to the conclusion that throughout two large districts to the north and south of that city the plumb-line is deviated in opposite directions. The deflections from the vertical are very considerable, and indicate a relative defect in the attraction exerted by the rocks in the neighbourhood of Moscow itself, and the suggestion has been made that there is either a huge cavity—a bubble in the earth-crust—under the town, or that the matter beneath it is less dense than that which underlies the surface strata on either side at a distance of ten or twelve miles. As long ago as 1853, Captain Meyen made magnetic observations in order to determine whether the same district is also the seat of any magnetic irregularity. His stations were hardly sufficiently numerous to lead to decisive results, but the magnetic elements have recently been measured by Dr. Fritsche at thirty-one places within fifty miles of Moscow. The experiments were all made within eleven days, so that no correction for secular change is required. They indicate a locus of magnetic attraction running through Moscow itself. South of the town the disturbance again changes in direction so as to show either that repulsive forces are in play, or that there is another magnetic ridge line still further to the south. Dr. Fritsche thinks that these observations explain the gravitational anomalies without recourse to the somewhat forced hypothesis of a vast subterranean cave. He assumes that there is a concealed mass of iron, which approaches near to the surface at Moscow, and also along two loci to the south and north of the city. He attributes the magnetic irregularities to the attraction of the central iron hill, the deflections of the plumb-line to the flanking masses. It is perhaps not inconceivable that such results might follow in a special case, but without the support of calculation it certainly appears that the magnetic experiments point to the existence of the principal attracting mass under the town. This is in fact the arrangement shown in the figure with which Dr. Fritsche illustrates his hypothesis. If this is so, the theory would *primâ facie* seem to require that the bob of a plumb-line should be attracted towards and not—as is actually the case—away from the centre of the magnetic disturbance. On the whole, then, though the coexistence of large magnetic and gravitational disturbances in the same place is suggestive, I do not think that they have as yet been proved to be hidden effects of the same hidden mass of magnetic matter."

### ELECTRIFICATION OF AIR BY SUBTRACTION OF WATER.

At the close of the delivery of the presidential address, Lord Kelvin gave a summary of a paper written by himself, Mr. Magnus Maclean, and Mr. A. Galt, entitled, "Preliminary Experiments, Proving the Electrification of Air by the Subtraction of Water from it." In his preliminary remarks Lord Kelvin set forth that—many years ago—Armstrong discovered that spherules of water driven by steam against a hard block would produce much electricity; he was led to this in the first instance by noticing that a locomotive on iron rails, resting on cinders and blowing off steam, would give electrical sparks. Later on Professor J. J. Thomson discovered that water falling on a plate produces electricity. Electrification is probably produced by falling rain. It had always occurred to him—Lord Kelvin—that the motes in air blowing against a mountain side, and clouds forming there, would produce electricity. He then gave the following abstract describing the experiments recently tried by Mr. Maclean, Mr. Galt, and himself:—"The experiments were commenced by one of us in December, 1868, but before any decisive result had been obtained circumstances rendered a postponement of the investigation necessary. A glass U-tube with vertical branches, each 18in. long and about 1in. bore, with the upper 8in. of one of the branches carefully coated outside and inside with clean shellac varnish, was held fixed by an uninsulated support attached to the upper end of this branch. The other branch was filled with little fragments of pumice soaked in strong pure sulphuric acid or in pure water; and a fine platinum wire, with one end touching the pumice, connected it to the insulated electrode of a quadrant electrometer. A metal cylinder, large enough to surround both branches of the U-tube without touching either, was placed so as to guard the tube from electric influences of surrounding bodies—of which the most disturbing is liable to be the woollen cloth sleeves of the experimenters or observers moving in the neighbourhood. This metal tube was kept in metallic connection with the outside metal case of the quadrant electrometer. The length of the exposed platinum wire between the U-tube and the electrometer was so short that it did not need a metal screen to guard it against irregular influences. An india-rubber tube—metal metallically connected with the guard cylinder would have been better—from an ordinary blow-pipe bellows was connected to the uninsulated end of the U-tube. Air was blown through it steadily for nearly an hour. With the sulphuric pumice in the other branch the electrometer rose in the course of three-quarters of an hour to about nine volts positive. When the pumice was moistened with water instead of sulphuric acid, no such effect was observed. This result proves decisively that the passage of the air through the U-tube gave positive electricity to the sulphuric acid, and therefore sent away the dried air with negative electricity. A corresponding experiment with fragments of chloride of calcium instead of sulphuric pumice gave a similar result. In repetition of the experiments, however, it has been noticed that the strong positive electrification of the U-tube seemed to commence somewhat suddenly when a gurgling sound, due to the bubbling of air through free liquid—whether sulphuric acid or chloride of calcium solution—in the bend of the U-tube began to be heard. We intend to repeat the experiments with arrangements to prevent any bubbling of the air through liquid. We have repeated our original experiment with pumice moistened with water in the insulated U-tube, and with an uninsulated U-tube filled with sulphuric pumice between the bellows and the insulated tube, so that the air entering it is artificially dried. With this arrangement the insulated U-tube was negatively electrified by the blowing of the air through it; but this electrification may have been due to the negative electrification of the dry entering air to be expected from the result of our first experiment. We intend to repeat the experiment with artificially dried and dis-electrified air blown through the U-tube containing pumice moistened with water."

He drew upon the black-board the accompanying diagram, Fig. 1, of the apparatus described. He added that he is now experimenting with Professor Tait to try whether, by suddenly exhausting air from a receiver so as to produce a cloud, and then sweeping the cloud out, electrification will be obtained; if the thing is possible; the vessel used must be much larger than any which they had tried hitherto.

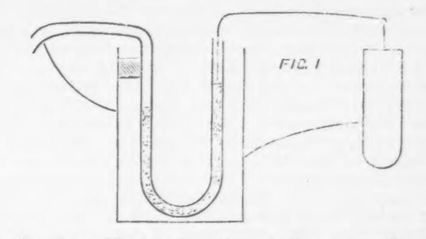


FIG. 1

Dr. Oliver Lodge, in the course of the discussion of the paper, said that if he had obtained the same results under the same conditions, he should have ascribed those results to friction. Lord Kelvin then combatted this conclusion.

### PHOTO-ELECTRIC LEAKAGE.

Dr. Oliver Lodge then brought the above subject under the notice of the Section, and called attention to the reseaches of Messrs. Elster and Geisted on the influence of the action of the extreme ultra violet rays of the spectrum upon electric leakage. One of their experiments substantially can be explained by Fig. 2. in which A B D is a Leyden jar, and E H a discharging channel. When the conditions are so evenly balanced that the jar tends to discharge itself without decided preference, either by E or by H, an ultra-violet light is then thrown upon either E A or H B, the light tends to prevent the production of the spark between the knobs on which it falls.

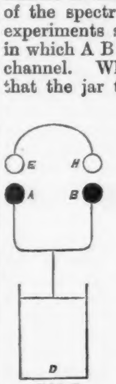

FIG. 2

Dr. Lodge also described an experiment of his own in which an insulated pewter pot—Fig. 3—was connected with an electroscope, and a beam of ultra-violet light directed into its inside, as indicated by the dotted lines. The pot was charged with electricity of high potential. When the beam went wholly inside the pot there was no leakage of electricity at all, but when any of the rays fell upon the rim or outside of the pot, electrical leakage proceeded apace.

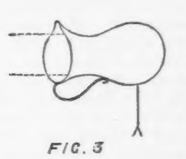

FIG. 3

Three papers upon thermo-dynamical questions by Mr. G. H. Bryan were then read, after which the proceedings of Section A closed for the day.

### STEAM CARRIAGES ON COMMON ROADS.

The work of Section G, the Mechanical Science Section, commenced with the delivery by Professor A. B. W. Kennedy, F.R.S., of his address as President. The address was warmly and deservedly praised, and contains some new points, and new ways of describing the work of the engineer. It will be found on another page.

The paper by Sir Frederick Bramwell, to which we referred last week, was the first paper read in this section. It will be found on another page. The discussion upon the paper did not add to it in any material degree. Its value was recognised as directing renewed attention to the work done by Hancock and Gurney, and to the important features of the water-tube boilers of several men of the same time, including the upwardly inclined fire-bar tubes of Gurney's boiler. It was thought that a careful study of these early examples of road carriages and boilers would have placed any practical engineer in possession of much that is essential to success. The rise and rapid extension of the railways was probably the chief cause of the failure to pursue the advantages reached by Hancock. The explosion of Gurney's boiler did much harm, but it was thought that with the encouraging report of the Royal Commission, this accident would not have had a lasting effect if public favour had not been so completely monopolised by the then new railroads.

### BORE WELLS FOR TOWN WATER SUPPLY.

After this discussion, Mr. Henry Davey read a paper on "Bore Wells for Town Water Supply," which we shall print in another impression. In the discussion upon it, Mr. G. F. Deacon referred to possible difficulties in carrying out Mr. Davey's system when sand was met with. When wells were constructed in the ordinary way and with headings, the sand could deposit and not affect the pump valves. Sir Frederick Bramwell thought there need not be any lasting trouble with bore wells for large supplies. He had obtained several supplies in this way. Mr. Davey said that sand caused no lasting trouble. The valve seats were, during sinking, faced with gutta-percha, and after the work was completed the ordinary metallic seats were put in. This completed the work of the first day of the Section.

On Friday morning Section A joined Section G for a joint discussion on four papers:—(*a*) on "Integrators and Analysers," by Professor O. Henrici; (*b*) on the "Behaviour of a Rotating Cylinder in a Steady Current," by Arnulph Mallock; (*c*) on the "Resistance experienced by Solids moving through Fluids," by Lord Kelvin; and (*d*) on the "Evolution of a Flying Machine," by Hiram S. Maxim. We dealt with Mr. Maxim's machine last week. Professor Arthur W. Rücker, F.R.S., took the chair. Lord Salisbury, the President of the Association, was present.

### EVOLUTION OF A FLYING MACHINE.

At the close of the reading of his paper, Mr. Maxim made some supplementary remarks to the effect that his finished engines originally weighed 300 lb. each, and that subsequent alterations brought their weight up to 322 lb.; by the various improvements he is able to make the pressure mount from to 200 lb. to 300 lb. in less than a minute; he thought that the engines would actually deliver 400-horse power on the screw. From experiments he had tried, he had come to the conclusion that there is practically no skin friction on a screw running in air.

Lord Rayleigh spoke of the skill, ingenuity, and perseverance which Mr. Maxim had displayed, and stated that he had had a ride on Mr. Maxim's machine; he reckoned that ride quite one of the sensations of his life, for to approach a wood at the speed of 36 or 37 miles an hour, with no visible means of stopping, is decidedly sensational. A few years ago, when lecturing at the Royal Institution, he touched upon this question of flying machines, and had to begin by defining one. Is a balloon a flying machine? He thought that the general answer would be "No." A cannon ball is not a flying machine because it cannot develope fresh energy. A rocket developes or produces fresh energy, but cannot be classed as a flying machine, which term he took to mean a machine capable of carrying a man through the air in any desired direction, and of descending with him in safety. The problem of the action of single aëroplanes was attacked and solved many years ago by a Frenchman, M. Penaud, as set forth in the *Journal* of the Aëronautical Society; he dealt with the question, at what angle to the horizon aëroplanes should be placed, without taking skin friction into account. Assuming the presence of no friction, a plane of any size can be made into a flying machine, provided only that it be driven fast enough. Penaud's results were substantially the same as those which he—Lord Rayleigh—had worked out afterwards, without knowing at the time what Penaud had done. He thought that it would be found eventually that skin friction will have to be practically taken into account in relation to flying machines. Mr. Maxim, he thought, had solved three out of, say, five of the problems of flight.

Professor S. P. Langley, of Washington, said that the making of a machine which will support itself in air, which he congratulated Mr. Maxim upon having accomplished, is not the greatest difficulty to be overcome in making a flying machine. Supposing his machine not to be guided by rails, but to begin to travel freely in the air, what is to keep it travelling in a horizontal direction? For instance, if he tried to throw the card in his hand across the room, it would require great power and skill to cause it to travel in a horizontal direction after it left his hand. In some experiments he had tried with speeds of fifty or sixty miles per hour, he had found skin resistance to be an almost negligible quantity. He had not tried to make a flying machine, nor had he ridden upon that made by Mr. Maxim; he thought that before the close of this century flying machines would have a real existence, but whether they would be commercially successful or navigable without great risk, he would not predict.

Lord Kelvin had unbounded admiration for the beauty and ingenuity of the engineering work connected with Mr. Maxim's flying machine, one part of which, however, he must attack, and that part was the aëroplane. Why was it used at all? Why not mount the screws on a vertical axis? About twenty years ago his brother, Professor James Thomson, made a little flying machine consisting of a pair of screws on vertical shafts. It would fly up to the ceiling and come gently down again. He was not sure that any description of it was published at the time, but it might have been brought before one of the Glasgow scientific societies. His brother, however, did not see the possibility of making this device into a machine which would lift a man. It was commonly assumed to be proved that the resistance to propulsion would increase nearly in proportion to the square of the velocity, but it is now found by experiment that it is not so; and it was also found that this was pointed out by Sir John Robinson, and Lord Kelvin said that if his brother had read Sir John Robinson's book, he probably would not have taken such a despairing view; besides, he had not anticipated the possibility of constructing such beautiful machinery as that produced by Mr. Maxim. Why did not the latter use four vertical screws, one at each corner of the machine? It would come down all right, and even if there were a strongish wind blowing, an adjustable aëroplane could be fixed below it by which it could be kept in a horizontal position. He thought that many inventors of flying machines had been misled by the eagle in the back yard which cannot get into the air, for such heavy birds must take a long run along the ground first. The machine of Mr. Maxim is an uncomfortable one in the matter of coming to rest after a flight, but his unprecedentedly light and powerful engines might be applied to a machine with vertical screws, in which he—Lord Kelvin—would be happy to have a fly.

Professor Osborne Reynolds stated that it was not usually noticed that there is an absolute limit to the weight which can be raised by any flying machine, namely, that weight of the materials used increased as the square of the increase of the size of the machine. The weight thus increases faster than it is possible to increase the strength. This law, he said, limits the possibilities of flight, but we may remark that this law may act asymptotically, and the absolute limit be a long way off. Birds are limited in size by this law; he thought the weight of the largest flying bird to be about 60 lb. or 70 lb. Mr. Maxim had been successful in getting power enough on a machine to lift 8000 lb. The wings of birds vary in dimensions according to their weight, and to the distances over which they habitually fly. The French partridge cannot fly slowly, its wings being so small in proportion to its size; birds which fly long distances have long wings. He thought that for actual flying by machinery the speed would have to be more like 200 miles an hour, than the speeds with which Mr. Maxim had been dealing, and that at high velocities the amount of skin friction would be serious.

Mr. Maxim, in reply, stated that he thought that a machine could be made with four vertical screws, but that these screws would have to be widely separated from the body of the machine, so as not to blow down upon the machine itself. He had found that an aëroplane shaped as in Fig. 1, would always lift as much as could be lifted by the power used to push it, showing that there is no skin friction practically. He had made a thing of the shape shown in Fig. 2, and nearly everyone would say that it is impossible that it should rise when pushed through the air in the direction indicated by the arrow. Yet it does rise, because it encounters stationary air at B, and at A leaves air going down, consequently it takes an upward flight.

To some of the Friday's papers and proceedings we must refer in another impression.

### NEW SPECTRUM DISCOVERIES.

On Saturday, August 11th, the theatre in the Clarendon Laboratory at Oxford was crowded to hear Professor S. P. Langley, of Washington, give a description to Section A of the British Association of the work he has recently been performing in the ultra-red end of the spectrum. Mr. R. T. Glazebrook, F.R.S., occupied the chair. As mention was made by the speaker of the work of the early Herschel's in the same domain, it may be mentioned that Professor Alexander Herschel was among those present.

Professor Langley stated that in early times Sir William Herschel, when testing the heating power of different portions of the spectrum, found, by thermometers, the heat of the visible spectrum to be greatest at the red end, and that in the invisible region outside the red the heat was still greater. Twenty-five or thirty years later, his son, Sir John Herschel, took some paper soaked in alcohol and rubbed over with lampblack, so that when one part dried before another, the resulting difference was optically perceptible, and he found the heat in the invisible ultra-red end of the spectrum to be unevenly distributed; three white spots appeared in that region with the spectrum which he used; he employed a round hole in the apparatus in place of a slit. Later still, a scientific man at St. Petersburg, working in the same region, used a thermo-pile to indicate the amount of heating power, and observed irregularities of temperature in the ultra-red of the spectrum. Some years ago he—the speaker—used his bolometer for the purpose—an instrument in which the amount of heating of an exceedingly fine flattened platinum wire is indicated by electrical means—to search for lines of the spectrum in this invisible region; it was groping and tedious work; he was two years in fixing the positions of less than twenty lines, and he came to the conclusion that life was too short for that method of work, for in mapping those few lines between 1000 and 2000 bolometer readings had been taken.

About five years ago he resumed the investigation, having obtained official aid from the Government of the United States. New and more delicate apparatus was constructed. In working, he had a spectrum moving over the bolometer wire, and a photographic plate moving synchronously with it, in order to get the true position of each of the lines. The clockwork had to be of the most perfect nature; and in the optical part of the apparatus rock salt had to be used in place of glass, the latter being in a great degree opaque to the ultra-red radiations. A rock-salt prism is mounted upon an azimuth circle, to which a most accurate motion is given by clockwork—as accurate, indeed, as that used to drive astronomical telescopes. The electrical changes are indicated by means of a reflecting mirror in the usual way, and he was much indebted to Mr. Boys for the accuracy ensured by the use of his quartz fibres. The whole apparatus is so sensitive and exact that at present it is quite capable of measuring one-millionth of a degree. When the feeblest spectrum line falls on the wire, a sharp and marked deflection immediately follows, and by this method he had already obtained about 2000 deflections in this hitherto unknown region. There was a time when he could not trace any heat in the double D-line, but he was at that moment able to show them bolometer indications of heat, not alone in each of the D-lines, but in the fine nickel line between them. The representation of this which he was showing them in curves upon paper was not a drawing, it was an automatic representation obtained by optical means and by photography, and was untouched by hand. By another optical method he had formed the curves just mentioned into a linear representation of that part of the spectrum, and they could see that the ordinary double D-line, with the nickel line between, had been the pictorial result. He exhibited also some composite photographs, in which several different images of the lines in the ultra-red end of the spectrum had been superposed by Mr. Francis Galton's method.

In this unexplored region of the spectrum it is believed that meteorological influences have much effect; they all knew that alterations in the weather had an influence upon the rainband in the upper spectrum, and that several parts of the spectrum are influenced by telluric action. He hoped, therefore, that the study of these invisible lines in the ultra-red part of the spectrum would ultimately give the power of predicting the weather, and that the American Government would feel that it had been justified in supporting these researches, for it had done so upon purely utilitarian grounds.

A member asked Professor Langley what optical method he used to turn his curved lines into a linear representation of the D part of the visible spectrum.

Professor Langley asked whether the questioner remembered those curious optical toys with which you look into a cylindrical mirror, and see an apparently distorted diagram turned into a figure of proper proportions. He employed the same principle with another optical arrangement superposed; there was no time at that meeting to enter into the full details, but if the optical constants were correct, the reproduction would be correct; the lines are drawn out by means of a system of ordinary and cylindrical lenses. There was a time when good rock salt for optical purposes was difficult to obtain, and difficult to work; rock salt prisms can now be admirably worked, and he thought that with the one he was using he could see five or six lines between the two D lines; at will he could run through the whole spectrum up a photographic plate, in a period varying from fifteen minutes to four hours. He then projected some photographic diagrams upon the screen, showing different parts of his apparatus in use in Washington, including a siderostat made by Sir Howard Grubb. He also projected an image of the ultra-red spectrum, and pointed out what a small length of it had hitherto been mapped by direct photographic means.

Mr. Norman Lockyer remarked that it was difficult to find words in which to express due admiration for the wonderful piece of work which had just been brought under their notice; it amounted, in fact, to a revelation, and he hoped that in time Professor Langley would be able to give them the spectrum of any particular part of the sun's disc which might be desired. He considered one of the advantages of British Association meetings to be the conflict of wits which they bring about, and the suggestion of new ideas.

Dr. J. H. Gladstone stated that Brewster was able to see with the eye some lines below A of the spectrum; he—Dr. Gladstone—could not do so, but was able to resolve lines at the other end of the spectrum which were invisible to most people. Water in the atmosphere gave all the telluric effects in the spectrum, and Professor Langley's work was likely to be useful in the direction which he had indicated.

Professor G. J. Stoney said that in some of his spectrum work, he used a transparent screen coloured with picric acid, which had the peculiar power of absorbing all the violet rays down to the line G, and being, so far as he could see, perfectly transparent to all the rest of the spectrum. Could Professor Langley get indications of the temperature inside the dark lines?

Lord Kelvin had never expected to see the D lines separated by bolometric means, and still less to see it indicate the nickel line between them; the fact was almost inconceivable. The circumstance that practically the same bolometric curves of the lines in the ultra-red part of the spectrum had been obtained three times in succession in one day, was proof of the trustworthiness of the results obtained.

Professor Langley thought that hereafter the spectra of different parts of the sun's disc might be obtained, also that the bolometer would give some rough idea of the temperature inside the lines of the spectrum. He felt like a man starting a museum, who had a great store of specimens piled upon shelves, for future classification and examination; only one part of the work had been done.

The chairman considered Professor Langley's work to be the most important that had been, or that would be brought under the notice of Section A at that meeting of the British Association at Oxford.

### A NEW CHEMICAL DISCOVERY.

Last Monday, at the meeting of Section A, Lord Rayleigh and Professor W. Ramsay announced that they had discovered a new gas in common air—one more inert than nitrogen—in consequence of noticing that nitrogen obtained from common air differed in density by about ½ per cent. from nitrogen obtained from other sources. They obtained the new gas by subjecting some common air to electric sparks, absorbed the nitrous fumes so produced with potash, and the excess of oxygen with pyrogallol and caustic potash, after which they found the residue to be neither oxygen nor nitrogen, although it contained a little of the latter gas. Its density was at least 19·09; they had obtained about a quarter of a pint of it. The gas gave a blue line in the spectrum, in the place of the blue line of nitrogen, but more accentuated.

The gas has also been isolated from nitrogen obtained from air, by causing that nitrogen to be absorbed by magnesium, and then the density of the residue gradually rises. The new substance constitutes 1 per cent. of the nitrogen of the air. One speaker remarked that there is room for three spaces, with an atomic weight of between nineteen and twenty-three in Mendeléef's table; but Lord Rayleigh would not express any opinion as to the gas being a new chemical element—he confined himself to stating facts. Another speaker suggested that the milkiness obtained by Professor Dewar in liquefying common air might be due to the substance under notice. The announcement of the discovery was made to the section briefly and informally, and not communicated in a paper.

On the same day, at a meeting of the General Committee of the Association, Sir Frederick Bramwell occupied the chair. The meeting was reminded that next year the Association will meet in Ipswich, after which an invitation from the Mayor of Liverpool was read inviting the Association to meet in Liverpool in 1896, and the invitation was supported by the principal of University College, Liverpool, and Dr. Oliver Lodge; the latter remarked that nearly all the accommodation required would be found in University College, which, however, is not in the best part of the town, so that they had better be prepared for that; there is a workhouse over the way. The invitation was accepted. An invitation to visit Toronto in 1897 was then given by the Canadian Institute of Toronto through its president, Professor Wright, supported by three or four other speakers from that place. The chairman explained that they had no power to fix a place of meeting so long in advance; a resolution was then passed expressing the hope that the invitation would be renewed at the Ipswich meeting next year.

Sir Douglas Galton, who for twenty-three years has been one of the most hard-working officers of the Association, and is an authority on sanitary science, was then elected president of the Association for next year. The opening meeting of the Association at Ipswich was fixed for Wednesday, September 11th, 1895.

On Wednesday, at another meeting of the General Committee, Sir Frederick Bramwell again occupied the chair. Professor A. W. Rücker, the treasurer, stated that the number of members at the Oxford meeting was 2321, and the amount received £2175. He added that the Association did not desire to accumulate more capital, and had made arrangements to equalise its expenditure more year by year, after which Sir Douglas Galton read the list of grants, which we publish on another page, to British Association Committees for scientific work during the coming year.

A separate section for Botany was then established, and a resolution passed—on the motion of Mr. Vernon Harcourt—that the word "Mineralogy" should be left out of the title of the Chemical Section, some of the papers on that subject being better suited for Section A. The Council was authorised by the meeting to draw the attention of the Government to the desirability of sending a scientific expedition to the Antarctic regions; after which the meeting was adjourned until September 11th, 1895, at Ipswich.

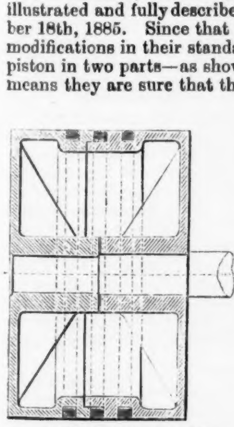
The concluding meeting of the Association at Oxford was held last Wednesday afternoon, with Sir Henry Acland in the chair; and, on the motion of Sir John Evans, it passed a vote of thanks to the Mayor, Sheriff, and Local Executive Committee of the City of Oxford, for the warm welcome which they had given to the British Association, and in which they had been so well seconded by the members of the University. The Mayor expressed pleasure at the grateful recognition of the work of the Corporation and of his brother citizens, and one of the local secretaries responded to the same effect. In responding to a vote of thanks to various Oxford University authorities, Dr. Boyd stated that when they heard that the British Association was coming to Oxford, the University authorities resolved to help in making the reception a good one, which action he hoped that the Corporation would receive in the same spirit in which it had been offered, and put it down on the credit side of the running account between them. Among the votes of thanks was one to Sir Henry Acland, Vice-Chancellor of the University, who said that his first work in connection with the Association was in 1834.

From all the opinions we have been able to gather, the members of the Association have been greatly pleased at the way in which they have been received in Oxford. At the general meetings of the committee of the Association the same content seemed to prevail, all the steps recommended by the Council having been adopted without amendment or discussion.

## BELGIAN MACHINERY AT ANTWERP EXHIBITION.

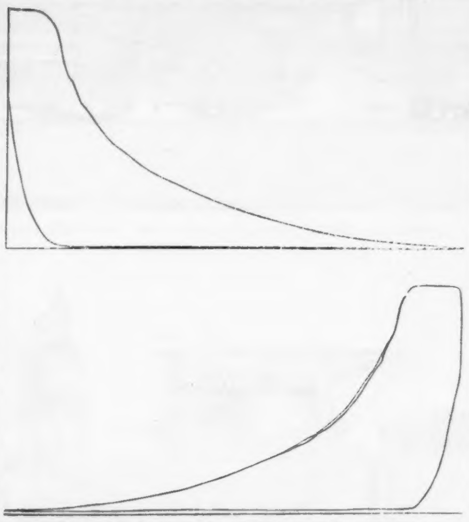
(*From our Special Commissioner.*)

The engines exhibited by Messrs. H. Bollinckx and Co., of Brussels, at the Antwerp Exhibition of 1885, were illustrated and fully described in The Engineer of December 18th, 1885. Since that time they have made several modifications in their standard type. They now cast the piston in two parts—as shown in the diagram. By this means they are sure that the sides are of equal thickness all round, and the pieces are more easily cast and cleaned than when the whole piston is in one piece. In turning the surfaces C and D, a slight difference is left in their diameter, and the two parts are then forced together by a hydraulic press, thus ensuring a steam-tight joint. Another modification is in the method of joining the connecting-rod to the crosshead. As mentioned in the previous description no keys are used for the fly-wheels, which are simply turned to a tight fit, and held together by four bolts. Messrs. Bollinckx have now adopted a similar plan for the connecting-rod ends. The end of the connecting-rod is bored to a diameter slightly less than that of the pin, and instead of being made round in the usual manner, it is split at the ends, which are lengthened, so that the split parts may be pressed together by a bolt. The pin is separate, instead of forming part of the crosshead, so that by slackening the bolt it can be slightly turned occasionally. Finally, they now use two excentrics, one for the steam admission and one for the exhaust, instead of having only one. They do not claim this as a novelty, as they say that twenty years ago they always employed two excentrics. Subsequently they thought it would simplify the machine to suppress one; but they have recently come to the conclusion that by using a separate excentric for the admission the engine works with greater elasticity, under varying conditions, such as a fall in the steam pressure of the boiler, or when it is used for the motive power of electric tramways.



BOLLINCKX PISTON

Messrs. Bollinckx have two engines at work. The larger one, a Corliss of 16in. diameter and 32in. stroke, is driving one of the dynamos of the Compagnie Internationale d'Electricité. The annexed indicator diagrams were taken from this engine whilst in the Exhibition. It is running very steadily at sixty-six revolutions per minute, and has been greatly admired by English visitors for the regularity of its movement. The other engine shown by this firm is a Rider, of 11¼in. diameter. 18in. stroke, making 100 revolutions a minute, but not driving any machinery.



DIAGRAMS FROM BOLLINCKX CORLISS ENGINE

It is often difficult to determine under what nationality an exhibit should be described. Many firms have factories in two countries, or occasionally the same object is made by two firms, which seem to join in exhibiting it. This is the case with a pair of very interesting water-tube boilers invented by Mr. Dürr, of the Düsseldorf-Ratinger boiler factory. They are not working at Antwerp, but were in use throughout the Chicago Exhibition, in the pavilion of Messrs. Krupp, where they supplied steam for erecting, working, and dismounting the cannon exhibited, and also for an ice-making machine. They might thus be classed as a German exhibit, but they are shown by the Ateliers de Construction et de Chaudronnerie d'Arvans, of Bierset Arvans, near Liège, who state that they were made in their works. The general arrangement of the tubes is like that of the Babcock and Wilcox, De Naeyer, or Belleville boilers, but they differ from all of these in having inner tubes which reach nearly to the bottom of the outer ones. Thus the Dürr may be described as a sort of modification of the Field boiler. The upper part of the boiler is formed by a horizontal tube. 5ft. diameter, surmounted by a steam dome. Below this are the rows of small tubes which slightly incline towards the back, and are held by plates, back and front. The front plate forms one side of a flat receptacle connecting these tubes with the large one above; and in the middle of this receptacle is a third plate, which carries the front end of the inner tubes. In some of these boilers there are two upper reservoirs; in the one shown only one, which is divided longitudinally by a central partition. The feed-water enters this to the right, and after passing to the end, and back on the other side, it goes down to the receptacle in front, and enters the inner tubes. The plate which holds these in position separates the water which is about to pass down the inner tubes from the steam which has been formed in the narrow space between the inner and outer, thus greatly increasing the circulation. By an arrangement of baffle plates, the flame passes four times among the tubes before it enters the flue leading to the chimney. The exhibitors say that this boiler was sent from Chicago to Antwerp without being cleaned, and the tubes still look like new. They also show a small working model in copper and brass, with glass let in, to allow the formation of steam and the circulation to be seen.

The exhibits of Messrs. John Cockerill, of Seraing, and of Messrs. De Naeyer and Co., of Willebroeck, which are by far the largest in the Machinery Hall, were noticed in The Engineer of June 8th, and those of several other Belgian firms on the 22nd. Steam engines are shown by several other firms, whose work is well known to your readers. The Phénix Co., of Ghent, has a 125 actual horse-power horizontal engine, of 22in. piston diameter, and 40in. stroke, driving a dynamo of 110 volts and 1200 ampères, It has also a 85-horse power, of 13in. diameter, and 18in. stroke, driving a loom and some Root's blowers. Both these engines are of the Hertay type, and are similar to those exhibited at Brussels, and described in The Engineer of February 22nd, 1889. They have also one gas engine in the Machinery Hall, and another 50-horse power works a continuous wire rope for drawing up the boats at Captain Boyton's "Water Show." In the main building are photographs of the pumps, &c., for heavy drainage work, which they have recently erected in Holland.

An engine shown by M. Jules Joly, of Saint Ghislain, is certainly the most extraordinary in the Exhibition. It is the invention of a M. Pierrez, who has made several machines of this type, which are now working in France. It is a single-cylinder horizontal engine; but the cylinder, instead of being fixed to the bed-plate, slides on it. The inventor claims that by adopting this system the strain on the foundations is completely abolished; but it seems evident that the strain has merely been transferred, and that whilst it is taken away from the holding-down bolts, which in an ordinary engine would keep the cylinder and front of the bed-plate in position, it has simply been added to the strain on the bolts holding the crank shaft plummer blocks. This is not necessarily a disadvantage, but neither is it a clear gain. The engine exhibited is 35-horse power; the cylinder is 12in. diameter; the stroke 19¾in.; the revolutions 100 per minute. There are three elbows on the crank shaft, the middle one being set at 180 deg. to the two others. The centre bend of the crank is joined to the piston by a short connecting-rod, and there are longer connecting-rods on either side from the other bends to brackets on either side of the back piston cover. Besides the belt wheel, the engine has two heavy fly-wheels. As the steam valve, governor, &c., must necessarily be fixed, whilst the valve chest is obliged to move backwards and forwards with the cylinder, the pipe connecting the steam valve with the valve chest has an expanding joint, sliding into a sort of sleeve at every stroke. This must entail not only extra friction, but loss of heat. The excentrics are on one of the same side cranks which serve for the connecting-rods of the cylinder. The engine is running regularly and smoothly, but is not doing any work. However, the exhibitors show a certificate from the Director of the Loos Penitentiary that one has been at work there for five years, without costing anything for repairs. Without conceding the wisdom of departing from the established custom of a fixed cylinder, the exhibit must be admitted to be interesting, and it would be still more so if, with equal boiler pressure, this engine could be tried against an ordinary horizontal stationary engine of the same diameter and stroke. There are several of these dimensions in the Exhibition, but it is not proposed to have any friction-brake trials.

Messrs. Van den Kerchove and Co., of Ghent, who were such important exhibitors in 1885, have only sent two engines to the Antwerp Exhibition this year. They are vertical compound engines, made from drawings supplied by Messrs. Willans and Robinson. One of them is driving a "Pieper" dynamo, making 460 revolutions a minute, and giving 100-horse power, for the Compagnie Internationale d'Electricité; the other works the "Farcot" ventilator, at the entrance of the British machinery section, illustrated on April 20th, page 326. Though to an English engineer a Willans engine is not a novelty, the workmanship is worthy of notice, whilst to some foreign visitors the design of these seems to be also new.

Though many of the coal-mining companies exhibit in the main building briquettes produced from their coal, there is only one firm in the Machinery Hall which exhibits briquette-making machines. It is the Société des Forges, Usines, et Fonderies, of Gilly. These machines are of two descriptions. The larger one, which can turn out fifteen tons per hour, is formed like a continuous brick-making machine, except that each briquette, which is 10in. by 6¾in., is automatically cut off by the machine at the thickness of 4in. This thickness can be varied at will, as can also the other dimensions, by inserting different moulds. Briquettes of this description are mostly used for the navy, and the exhibitors have recently supplied several of these machines for use in Cardiff. The other make of machine produces ovaloid briquettes, intended chiefly for household purposes. Two pairs of rolls, each with ninety-six cavities on the rim, are carried on a heavy joist frame, and driven by mill-gearing, the material being fed into them from a hopper on the top, fitted with a slide by which the rate of feed can be varied. In the machine shown, the briquettes are 3¼in. by 2½in. by 2in., but the exhibitors make others of larger as well as smaller dimensions. At 2½ revolutions per minute the output of this machine is five tons per hour.

Messrs. J. Leveque and Co., of Herstal, exhibit some compressed air riveters. Although, as a general rule, water is probably safer than air as a medium for conveying pressure, there are frequently positions to which it cannot conveniently be conveyed. In these cases, as well as during severe frosts, Messrs. Leveque's riveters can be used, when hydraulic power would not be available. In its simplest form this tool resembles a hydraulic riveter, with an elastic tube conveying air, instead of water, from the source of supply at a distance. Another type has the air pump on the same frame as the riveter, so that it is self-contained; and it is suspended through its centre of gravity in both directions, so that it will work in any position. A further development of this apparatus is a travelling riveting machine running on rails. On the same platform are a small steam engine, a boiler, air pump, air reservoir, forge with blower, and a crane which can turn in any direction. This crane, which has a movable jib, stands in front of the machine, and from it the riveter is suspended. A large steering wheel at the side has a small tooth wheel on the same shaft. A chain passing round this turns a larger tooth wheel on one of the axles of the wheels which run on the rails; and with this one man can easily move the machine backwards or forwards. The same firm show a double-flue boiler with cross tubes, and some other examples of the riveting which has been done with their machine.

Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Fleet engineers: W. H. Davis to the Royal Sovereign, and G. Rigler to the Benbow. Staff engineer: J. R. D. Johnson to the Sultan. Engineers: R. K. Herbert to the Malabar, C. H. Hill to the Boadicea, and R. S. Jennings to the Bonaventure. Assistant engineer: W. H. Glasspole to the Magdala. Probationary assistant engineers: J. J. Shirvell and Alfred Murray to the Malabar.

# AMERICAN LOCOMOTIVES

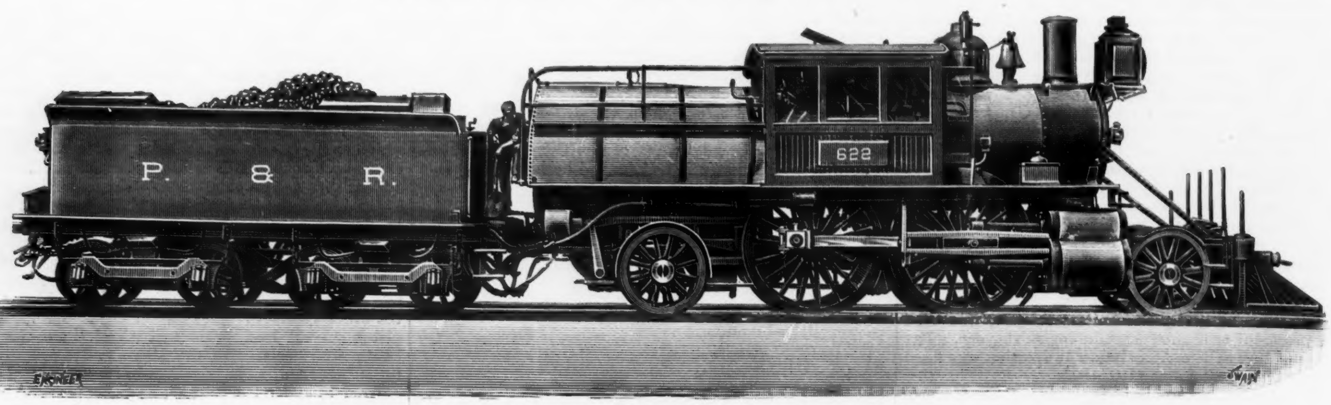


Fig. 1—COMPOUND ENGINE, PHILADELPHIA AND READING RAILWAY.

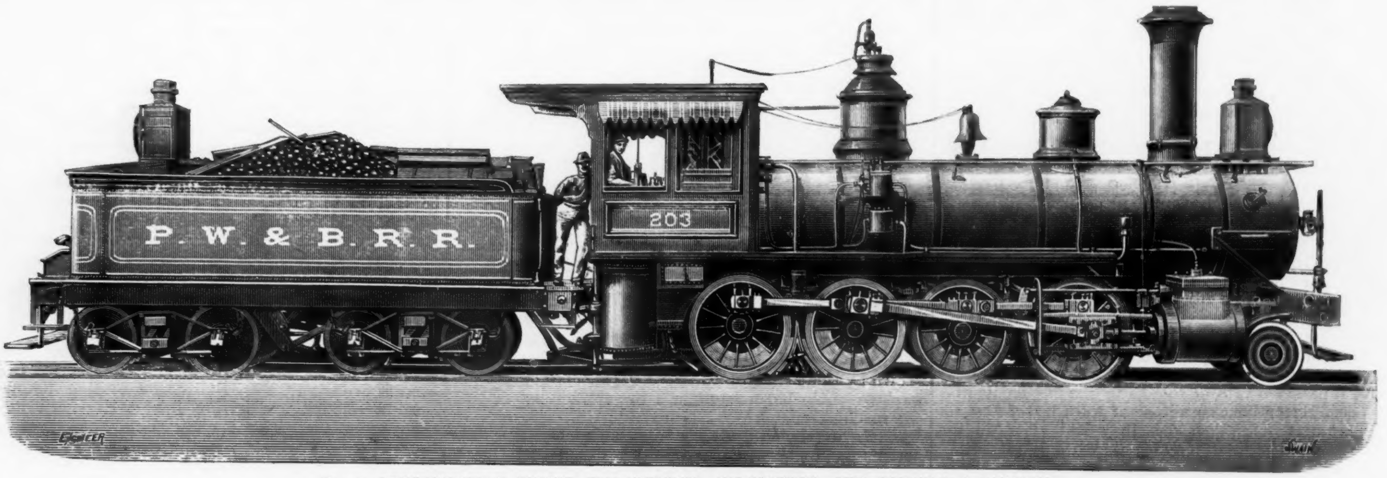

Fig. 3—CONSOLIDATION ENGINE, PHILADELPHIA, WILMINGTON, AND BALTIMORE RAILWAY.

## RAILROADING IN AMERICA.

By an English Railway Engineer.

### LOCOMOTIVES.

Probably no subject has during recent years received more attention in the technical Press than that of American railways and locomotives, and the author of the present articles is well aware of the fact that it will be somewhat difficult to treat the subject without re-covering already well-trodden ground; but, after a prolonged visit to the United States during the past autumn, when every facility was given to him for obtaining information regarding the working of and the plant employed on the numerous great railway systems, he hopes to be able to place before the readers of this journal—particularly those more directly interested in this branch of engineering—some interesting facts which have not hitherto received the attention which they deserve. The present article will deal only with locomotives, some of the leading types of which will be illustrated by reproductions of photographs specially taken; but in later articles the rolling stock, permanent way, signalling, &c., will be discussed. And here it may be stated that the author does not intend to dwell upon the theoretical principles involved so much as to point some of the leading features of American practice. Regarding the performances by American engines—of which much has been heard in this country of late — it need only be remarked that these could be easily accomplished by English engineers if similar services demanded them.

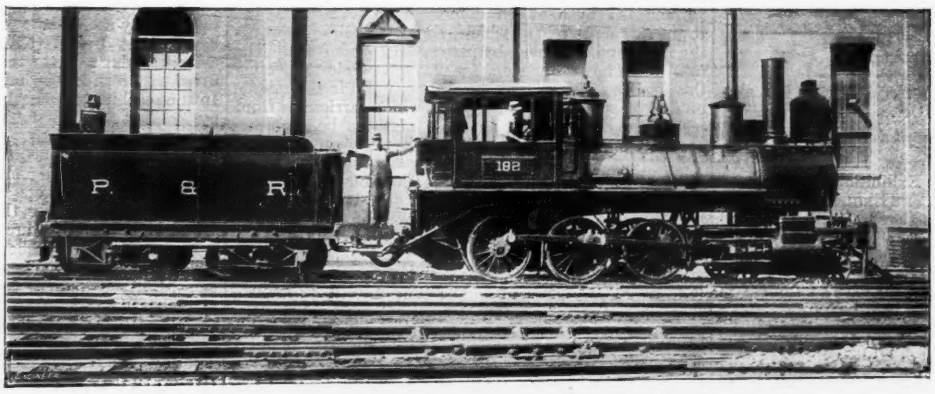

Fig. 2—FREIGHT ENGINE, PHILADELPHIA AND READING RAILWAY.

The total length of the world's railways is estimated at 375,000 miles, a distance sufficient to girdle the earth about fifteen times; and of this aggregate the United States provide 175,000 miles, or nearly one-half. This enormous system must of necessity involve many new departures in permanent way, equipment, and working, and the long journeys of the through trains, the variety of roads, their conditions, and the different climates passed through, all tend to lend interest to the subject.

At first sight a person accustomed to English trains is liable to imagine that those of the States are heavy and clumsy. Standing over 15ft. to the top of the chimney, with cylinders invariably outside the frames, the boiler pitched high, and a large cab often situated on top of the boiler, the locomotive seems even larger than it is, whilst the long cars, always observed from about the level of the rails, and measuring seldom less than 14ft. to the top of the deck-light, tend to corroborate the idea of hugeness; but when once the eye becomes accustomed to the size and arrangement of the engines, and when an opportunity has been afforded of a trip in the cars, one must admit that the train, as a whole, is well adapted to the requirements; and few could be instanced on this side of the Atlantic which will compare with them for convenience and comfort.

It is not intended here to compare the American and English locomotives, as that has often been done in the Press, and frequently, it would seem, by writers who have not had the opportunity of seeing both types at work. Each has its particular duty, and perhaps where the American engine is successful the English one might fail, and *vice versâ*; but the author is convinced that the Yankee locomotives are well adapted for their work, and in many cases an English engine would render only a moderate account of itself when put to similar tests. As already suggested, American engines as a rule are more powerful than ours, boilers, cylinders, &c., much larger, while the fire-box is often enormous, even comparatively. Steam pressures, too, are higher than in this country, 180 lb. to 200 lb. per square inch being those most generally adopted. We some time back illustrated one of the fine express engines of the New York Central Railroad, with drivers 6ft. 6in. diameter, cylinders 19in. by 24in., grate area 27·3 square feet, and constructed for a working pressure of 190 lb. per square inch. The total weight of this engine in working order is 56½ tons. The tender, weighing 17 tons when empty, has a water capacity of 3500 gallons and a coal capacity of 6¾ tons. Locomotives of this type were employed on the New York Central Railroad for part of the journey of the "Exposition Flier," viz., from New York to Chicago, a distance of 980 miles being covered in 20 hours actual time. The various stages of the journey with their respective times are shown in the annexed Table A.

When the weight of this train, comprising five cars weighing about 40 tons each, is considered, this is a very creditable performance.

Although the New York Central Company boasts of engines to beat this class in speed and power in the famous "No. 999" engine with its record of 100 miles per hour, these engines are typical of the modern American express, and the four-wheels coupled engine with a leading bogie has been the favourite type of American designers for years. A few roads are, however, trying a new arrangement—shown in Fig. 1. This represents a fine compound for the Philadelphia and Reading Railroad, and has the four-coupled drivers placed between a single pair of leading and trailing weeels. The chief dimensions are as follows:—Cylinders—Vauclain—13in. and 22in. by 24in. stroke; drivers, 6ft. 6in.; truck wheels and trailers, 4ft.; and the total weight in working order of the engine is only 58 tons. It will be noticed that the truck wheels in this engine are much larger than usually put under American engines, 3ft. being rarely exceeded.

Freight trains in the States are very heavy—often 2000 to 2500 tons — and are usually hauled at low speeds. The engines for this service are consequently very powerful, but not capable of developing high speeds. Two examples of goods engines are given herewith. Fig. 2 shows a six-wheeled coupled freight engine with cylinders 19in by 26in., and drivers 4ft. diameter; and Fig. 3 represents a "Consolidation" engine of the eight-wheels coupled type, with cylinders 20in. by 24in. and drivers 50in. in diameter, as employed for goods traffic on the Philadelphia, Wilmington and Baltimore Railroad. These are not, however, the most powerful engines built in the States, as it may be remembered that the Baldwin Company exhibited at the late Chicago Exhibition a compound "Decapod" ten-wheels coupled engine with cylinders 16in. and 27in. by 28in., drivers 4ft. 2in., and weighing nearly 90 tons in working order. The boiler is 6ft. 2in. inside diameter, and the barrel 12ft. long, made of steel plates ¾in. thick. The working pressure is 180 lb.

Table A.

| Miles. | | | Eastern time. |
|---|---|---|---|
| 0 | Leave | New York City | 3.00 p.m. |
| 143 | ,, | Albany | 5.50 ,, |
| 238 | ,, | Utica | 7.40 ,, |
| 291 | ,, | Syracuse | 8.50 ,, |

| 869 | ,, | Elkhart | 7.42 ,, |
| 980 | ,, | Chicago | 10.00 ,, |

per square inch. This engine was intended for service on the New York, Lake Erie, and Western Railroad.

Tank engines are used on most suburban lines for short "runs;" but "switching"—or, as it is termed in this country, "shunting"—is apparently almost entirely performed by tender engines, the tender being specially constructed with a sloping tank, to give the "engineer," or driver, an unobstructed view of the trainmen when coupling, &c. Fig. 4 shows a switching engine as used on the Canadian Pacific Railroad. It has cylinders 19in. by 26in., and drivers 4ft. 4in. diameter.

On the Elevated roads some very small and neat engines are employed. On the Chicago South Side Railroad all compounds of the Vauclain type are used, and have cylinders 9in. and 15in. by 16in., drivers 3ft. 6in., and four wheels coupled with a trailing bogie; total weight, 25 tons. These haul five passenger cars weighing 100 tons full, and make excellent time. They start quickly, and pull up extraordinarily sharp with the quick-acting air brakes. The tank engine shown in Fig. 5 represents one built by the Grand Trunk Railway of Canada, and used for Montreal suburban traffic. The wheels are 5ft. 6in. diameter, and the cylinders 18in. diameter by 24in. stroke. Fig. 6 shows an exceptionally heavy engine of the Canadian Pacific Railway, having cylinders 19in. by 24in., and drivers 5ft. 4in. diameter. This engine is carried on fourteen wheels.

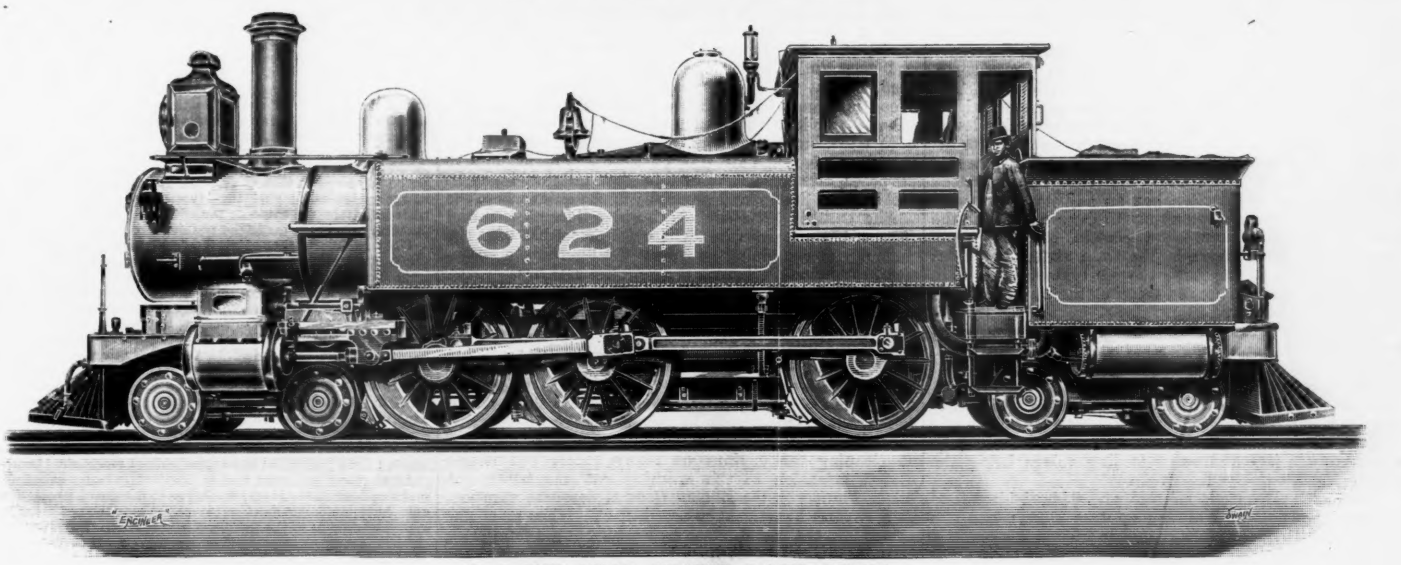

Fig. 6—TANK ENGINE, CANADIAN PACIFIC RAILWAY

Referring to some of the constructional details of American engines, wrought iron driving wheels are used on some roads. Cast steel appears to be rapidly coming to the front for this purpose, but cast iron claims the majority. Wheels of this material are cast hollow, and usually with the rim cut into segments, to allow the wheel centre to contract without straining the spokes and rim. The spaces between the segments are filled in with white metal blocks before the tires are shrunk on. The method of securing the tires varies; many roads, however, adopt the Mansell ring, or a modification thereof. The axle-boxes are frequently of cast iron having brass steps let in; while cast iron, paper, and wood are all largely used for truck wheels. Balanced slide valves, it would seem, have proved successful in the States, judging from the number of engines so fitted. Fig. 7 shows a section of an arrangement which is largely adopted. This is known as the Richardson balanced valve. It is very simple. Round the back of the valve a groove A is cut, in which four cast iron strips B—if a rectangular valve — are placed on edge, dovetailed at the corners to make steam-tight joints, and an adjustable wearing plate C is provided for these strips to work against. The compound systems are growing in favour, but the Vauclain type appears to be that chiefly used, and is already too well known in this country to require more than a passing allusion in this article. Metallic packing for piston-rod glands and valve rods is used to a large extent. A make much patronised is the United States packing, of which a sketch is given in Fig. 8. The con-

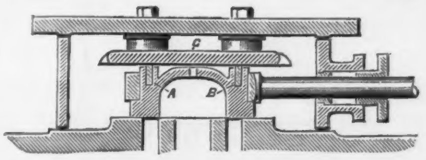

Fig. 7

struction of this will be easily followed, the metal packing rings being compressed by the spring shown;

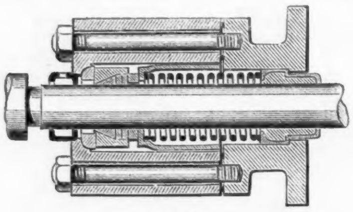

Fig. 8

over 300 roads, it is stated, make use of this packing. Steel fire-boxes are general; mild steel plates $\frac{5}{16}$in. to $\frac{3}{8}$in. for the side sheets, and $\frac{1}{2}$in. thick for the tube plate being used. Tubes are comparatively large, being 2in. diameter, and usually of charcoal iron. For renewal these are pieced by welding on fresh lengths at the fire-box end about 1ft. long, and often tubes may be seen ready for re-insertion in the boiler entirely made up of these short lengths welded together. To secure a water-tight fit, it is customary to put a thin copper thimble over the tube at the fire-box tube plate before expanding. Instead of making the fire-box long and narrow to fit in between the bar frames, many of the railway companies are now adopting wide and shallow fire-boxes placed above and slung to the frames by links pinned to cast iron shoes placed on the frame; rubbing guides are also provided. As an example of this system, see the illustration of the Philadelphia and Reading engine—Fig. 2.

Safety valves appear to be universally of the "pop" pattern, giving an instant relief for excessive steam pressure, and closing immediately the excessive steam has "popped" away. These valves are very noisy in operation, and some roads attempt to remedy this defect by muffling the escaping steam. The engines of the Philadelphia and Reading Company have a U-shaped strainer arranged around their safety valves, which quietens the discharge very considerably. Blast pipes are usually made very small, being only 3in. diameter for 18in. cylinders, and 3¼in. for cylinders 19in. diameter, these being common dimensions; while an independent blast nozzle is fitted for each cylinder. The excessive wear and tear of the fire-box, tubes, &c., due to the use of these small pipes, has led many builders to make their pipes so that nozzles of varying sizes can be bolted on, to change the orifice for different work. Most of the engines exhibited at the late Chicago Exhibition were thus provided, three nozzles of 3in., 3¼in., and 3½in. diameter being fitted with 19in. cylinders. This arrangement, however, is obviously not so convenient as a variable blast pipe operated from the footplate, as on our Great Eastern system, in which arrangement a hinged cap of suitable size for heavy work can be instantly brought into service, whilst by removing this cap and enlarging the outlet, a reduced blast can be produced for favourable parts of the road, thereby reducing the consumption of fuel and the back-pressure in the cylinders. No doubt the large grate area and the extended smoke-box add to the necessity for a powerful draught; but to hear an American freight train ascending the steep gradients of the Alleghanies, is an event not likely to be easily forgotten by an English railway man.

The extended smoke-box mentioned above has practically replaced the old-fashioned "diamond" smoke stack, and is evidently much favoured. On the Philadelphia and Reading Railroad the front of the smoke-box or door forms a "register," or circular ventilator for admitting air when the blast is excessive; this can be operated from the footplate. Some other roads have a similar device arranged around the chimney base.

Cabs are very large and commodious, wood as a rule being used in their construction; but some are made of sheet iron, lined with wood, notably on the Canadian Pacific Railroad. The outlook from an American cab is novel, and a fine view of the track is obtained, especially when the cab is placed at about the middle of the length of the boiler, as on the engine shown in Fig. 1. The driver is accommodated with a padded seat at the right-hand back corner, and all the handles, reversing lever, throttle, brake valve, &c., are placed conveniently to his hand. An elaborate array of fittings usually presents itself on stepping up into the cab, even a clock being provided. This often has an adjustable red hand which can be set by a thumb-nut to denote the time the train is appointed to reach a certain stopping place. Another excellent device is the train signal apparatus working in connection with the air brakes. This is in constant use for starting and stopping the trains, and will be referred to later on in this article.

Sight-feed lubricators are provided, and are usually a combination for oiling the valves and cylinders and also the brake pump, as well as cups communicating by pipes to the driving boxes, &c., from the cab. The bell, common to all American engines, is on some roads caused to ring by steam or compressed air, and mechanical sanding devices are in use, but are not so general as might be expected, air jets and screw-feeding valves being the chief systems employed.

The boiler clothing is effected with "blued" iron, and is decidedly neat and always appears clean; and one wonders how it is that it has not been tried in this country. It always preserves its blue colour, and dirt does not adhere to it as it does to the paint and varnish used here. The number of the engine, too, can always be detected at night, a side glass being provided in the headlight with the figures plainly painted thereon. On some roads an electric headlight is being used, a small motor and dynamo being placed immediately behind the lamp for generating the electric energy required. The finish generally of the engines is neat, although several working parts are left quite "in the rough." Side rods, for instance, are seldom machined the whole length as in this country, but are simply left black and painted between the coupling pins.

Air pressure brakes are in use on all passenger trains, and many freight trains. The New York and Brooklyn elevated railroads, however, have a vacuum brake. The Westinghouse quick-acting brake appears to have a formidable rival in the New York air brake; the exact advantages of the rival systems, however, seem hard to understand, both being apparently so similar in construction and working. On the pump, however, the New York Air Brake Company claim a distinct improvement, and judging from the number in use, it probably is entitled to its claim. The duplex air pump has four cylinders, two for steam and two for air. The action is smooth, and is said to give a higher efficiency than the ordinary single-acting pump. The steam cylinders are underneath the air cylinders, which allows natural drainage and ensures the compression of clean dry air, as impurities and the condensation from the steam cylinders cannot leak into the air chambers. The action of the pump in compressing air is similar to that of using steam in a compound engine. In the No. 1 pump—small size—both steam cylinders and the high-pressure air cylinder are 5in. diameter, the low-pressure air cylinder is 7in. diameter, and is twice the capacity of the steam cylinder driving it. In operation both air cylinders are filled with free air; the high-pressure piston remains quiet until the air from the large cylinder is compressed into the small one; then the high-pressure cylinder completes the compression and forces the air into the reservoir. Thus two measures of steam are made to compress three measures of air. This duplex arrangement of pump allows the valve gear to be made very simple. Ingenious valves are used to regulate the action of steam brakes on the engines, that is, to remedy the "leaking on" of the brake to its full power by the wire-drawn steam passing the engineer's valve and gradually attaining maximum pressure. An excellent form of brake shoe, too, is largely adopted, in which the surface of the shoe that would grip the tire on that portion of the tread D where it has most wear is cut away, and the friction of braking is taken on the edge of the flange and the extreme edge E of the tire, thus assisting to retain the original section to which the tire was turned. This is shown in the accompanying sketch — Fig. 9.

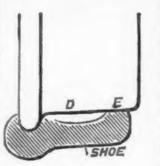

Fig. 9

Tenders are usually large, with a capacity of from 3000 to 4500 gallons of water, and some six to eight tons of coal, they are usually carried on two four-wheeled trucks; the tanks being of the "horseshoe" pattern, with coal space in the centre. The framing is of wood—white oak—but iron and steel are being adopted on new tenders on some roads. The wooden ones are, however, stated to be preferred, as they withstand the shocks due to rough hard roads better in winter, and if damaged by mishap they are cheaper and easier to repair. On some roads the sides of the tanks are made with a top curved inwards in place of the usual coping, the fuel being kept in its central space by a light railing. These look very neat and compact. Where the firing is done from the tender footplate, as is the case on most of the Philadelphia and Reading Railroad engines, a second cab is sometimes provided to cover the fireman, in addition to that for the engineer on the boiler. The connection between the two is made by steps to a raised running board or platform provided with handrailing. For lubricating purposes petroleum or petroleum compositions are used to the exclusion of all others for locomotives and cars. To prevent heating of the tender boxes on fast runs, the writer noticed the provision of a small flexible hose to convey cold water from the tender tank to each box, if desired, on some engines used on special fast services.

As regards fuel, on the Philadelphia and Reading and several Eastern roads, anthracite is used, the fire-boxes being specially made and unusually large. Bituminous coal is commonly used on other Eastern and Western roads, but on the "crack" trains of the Pennsylvania and New York Central and other roads furnace coke is used, so that the engines may be absolutely smokeless. Wood is largely burnt on the Southern roads, and gives off vile smoke with showers of sparks. Petroleum has been tried, but the systems experimented with do not appear to have been altogether satisfactory for locomotive purposes, otherwise it is certain that oil would pay as fuel in some States, and especially in the cities where the smoke emitted from engines burning bituminous coal proves very disagreeable. The chief defect has been the difficulty of combining an effective oil-burning arrangement interchangeable with the ordinary coal fire.

Locomotives in the States generally make a greater mileage in a given time than in this country, with a consequent shorter life. The system in vogue for working the locomotives is as follows. When an engine arrives in the "round-house," and as soon as the tubes have been cleaned by steam jets, fresh fuel and water taken on, and the engine oiled up, a fresh engineer and fireman will take it out. This system has one drawback; it prevents much cleaning being done—in fact, no pretence is made at cleaning the engines on many roads, but it also directs attention to the washing out the boiler. A method in use on the Illinois Central deserves mention, as it appeared particularly expeditious. When an engine comes into the round-house for washing out, a connection is made by a flexible hose to a pipe running round the shed roof, and the steam in the boiler is led away by it to "heat up" the water in a large storage tank. When the pressure has thus been reduced to about that of the atmosphere, the hot water is run out through pipes, also leading through and to storage tanks. The boiler, being then empty, is washed out as follows. Two mud plugs are provided on each engine; one is a connection to a curved nozzle, permanently secured inside the barrel of the boiler, next the smoke-box, and directed along the bottom of the boiler shell; and the second admits of a cross pipe being inserted above the top row of tubes immediately behind the fire-box. This cross tube has a blank end and perforations so placed that they come opposite the passages between the fire-box roof stays. Hot water at a pressure of 100 lb. is then forced into the boiler through these two connections, scouring the bottom of the boiler barrel and cleaning the dirt from the fire-box roof. After these operations have been completed, the boiler is refilled after washing out from the storage tank previously referred to, the fire lighted, and the engine is then ready for the road. This procedure is highly spoken of, and has the decided advantage of preventing unequal expansion and contraction of the boiler plates due to the great changes of temperature which accompany the system in vogue in this country for instance.

In another system a semicircular pipe is placed in the boiler shell at the smoke-box end, having several nozzles directed along the boiler barrel, and through which hot water is forced as in the previously mentioned system.

## THE CRITICAL SIDE OF MECHANICAL TRAINING.*

By Prof. A. B. W. Kennedy, LL.D., F.R.S., M. Inst. C.E.

While there is no place in the kingdom more suitable for a meeting of the British Association than Oxford, and certainly no place in which it is more delightful for the members to meet, it is yet to be admitted that there are few places which have much less in common with the special work of Section G. Nominally devoted to "Mechanical Science," the Section has for many years especially dealt with those branches of applied mechanical science which constitute the business of the engineer—to quote the well-known words of the Royal Charter, "the art of directing the great sources of power in nature for the use and convenience of man." The association of this ancient and learned city with boilers and chimneys, with the noise and racket of ordinary mechanical work, seems an incongruity. Even the harmless necessary railway station is kept as far away as possible, and the very river flows with a quiet dignity which seems to shut out the thought of anything more mechanical than the most ancient and futile of water-wheels.

Naturally enough these considerations did not tend to make more easy the choice of a subject for this address, and I have come very near to agreement with a recent critic in the opinion that presidential addresses are, in fact, almost immoral in the nature of things, and fit only to be abolished. Finally, I decided upon taking up my present subject, as being one in which the academic rather than the technical side of our work comes to the front, while at the same time it does not lead me out of lines in which I have been able, in past years, to work myself. It is now twenty years since I first took any active part in the scientific training of engineers, and five since I ceased to do so. I have often wished that I may have been at all as successful in teaching others at University College as I was, at the same time, in teaching myself. And since I have ceased to teach I seem to have been spending my time in finding out how much better I could do now than was possible when I was actually engaged in it. This may be pure imagination on my part; there is nothing more easy, as we all know, than to suppose that we know best how to do the things that other people do, and not the things we have to do ourselves. Indeed, I understand that this is the recognised attitude of the really superior critic. If, however, in anything which I have to say, it should seem that I am finding fault with what is now being done, I may at least point out that most of all I am finding fault with myself for not having done right when I had the opportunity—an opportunity which can now never recur. Indeed, instead of the decorous and unobtrusive heading which I have given to this address, I might have indicated its general lines almost as truly if I had entitled it "The Regrets of an Emeritus Professor"—a name which, on a suitable binding, might even have secured it a sale at the railway bookstalls.

I know well—too well—that in the present congested state of the engineering profession there are many of us who do not like to hear the word "training" mentioned at all. It seems to mean merely the preparation of more lads to struggle for a share of work that is even now insufficient to go round. There is no doubt much to be said for this point of view. But against it one must remember that all other professions are equally full, and that, after all, lads must do something. The fault is surely that there are too many lads! If our population is really to go on increasing as rapidly as at present—the benefits of which Sections D, E, and F might have a joint meeting to discuss, if not to discover—it is inevitable that demands should come for more and more complete professional preparation. The man of exceptional parts will come to the front under any conditions, training or no training, in the future as in the past. But for ordinary men—that is for 99 per cent. of us—it is essential that no advantage should be given to a rival in the fierce competition of life, and for them therefore it is of an importance hardly to be exaggerated to obtain the most complete and perfect training possible. At the same time, and on purely general grounds, it can hardly be denied that to raise the standard of our profession is indirectly to confer a benefit on the whole community. I hope therefore that in making certain suggestions about the training of engineers, it will not be thought that I am desirous of increasing their number, which is really an end as far as possible from my own wishes. Whether the number increases or stands still, or falls off, it is of importance from every point of view that those who come forward should be as well prepared as possible. And even the most conservative of us are compelled to recognise that the standard required in engineers' offices now is enormously higher than it was thirty years ago. This may truly be either the cause or the effects of improved training, but in either case it has made the training itself a necessity.

The particular aspect of mechanical training of which I wish to speak is its critical side. I do not know how a man should be trained to be an inventor. I would not tell anyone if I did. To be a creator in mechanical matters—which, however, is a quite different thing—is a faculty given only to a very few, and with them it is "born, not made." Many of us, however, without being either inventors or creators, have sufficient natural aptitude or inclination towards things mechanical to form a basis for the trainer or educator to work on, with some hope that he may be of service. About the sciences which should be taught to such men, or the methods of teaching them, about the extent and nature of their experience in shops or on works, I do not intend to speak. I shall confine myself to one aspect of the training only, an aspect which is perhaps not always sufficiently clearly kept in view—the aspect which I have just called the critical side of mechanical training.

An engineer is a man who is continually being called upon to make up his mind. It may be only as to the size of a bolt; it may be as to the type of a Forth Bridge; it may be as to the method of lighting a city, or only as to the details of a fire-grate. But whatever it is, once it is settled it is decided irrevocably—it is translated into steel and iron and copper, and cannot be revoked by an Act passed in another session. The time given him in which to decide may be a day, or a month, or a year, but in any and every case—so far as my own experience goes—it is about one-tenth part of the time which he would like to have. It is only in rare cases that the decision is obvious—most often there are more courses open than even the most facile politician ever dreamt of. The matters are too complex to be dealt with mathematically or even physically; even if they were not, there are few engineers who would have the special capacity to handle them. Moreover, their solutions are seldom "unique." From this point of view, the whole use of college training, of workshop practice, of practical experience, is to provide the engineer later on with the means of critically examining each question as it comes up, of reviewing systematically the *pros* and *cons* of each method of dealing with it, of coming finally, rapidly, and positively, to some defensible decision, which may then be irrevocably carried out.

---

* Address to the Mechanical Science Section of the British Association, by the President of the Section, at Oxford, 9th August, 1894.

In the case of a problem in pure mathematics or physics, where only one right solution can exist, that solution is arrived at by the help of a thorough knowledge of the science in question—there is little room for the critical faculty except as to method—the result is either right or wrong. With our work, on the other hand, solutions of all problems, except the very simplest—in other words, decisions on all points which present themselves—can be arrived at only by a process of criticism applied to the problems, to their statement, to their condition, to all their many possible solutions. The development of the necessary critical faculty should be one of the chief aims of every teacher and every student. A scientific training cannot make a man an engineer. Perhaps it is impossible for anything to make a man an engineer unless he has grown that way from the beginning! But a scientific training may make him, or at least give him the possibility of making himself, a critic.

In the vigorous attempts which have been made to specialise the education of engineers very early, I am afraid that the idea of teaching subjects is sometimes too prominent, to the neglect of matters less obviously useful. It is, of course, one thing to know a subject from the examination point of view, and quite another to be able to think about it, and still another to be able to write about it. In particular, I have often regretted to find how little attention has been given to a matter which perhaps may be called literary rather than scientific, but which is all-important in criticism, I mean to the power of expression. It is not easy to overrate the importance to the engineer, as to other folk, of the power of saying clearly what he means, and of saying just what he means. I do not mean only of doing this for its own sake, but because if a man cannot say or write clearly what he means it is impossible that he can think clearly. By the power of expression I do not mean, of course, the mere power of speaking fluently in public, a thing which appears physically impossible to some people; I mean rather the power of expression in writing, which carries with it clearness and consecutiveness of thought. It is difficult to know how this matter can be taught, but at least it can be insisted upon probably to a much greater extent than is commonly the case. A man requires to see clearly not only the exact thing which he wants to say, but the whole environment of that thing as it appears to him. Not only this, but he must see the whole environment of the same thing as it appears to the persons for whom he is writing, or to whom he is speaking. He has to see what they know about the matter, what they think, and what they think they know, and if he wishes to be really understood has got to do much more than merely write the thing he means. He has carefully to unwrite, if I may use the expression, the various things that other people will be certain to think that he means. For after all, the great majority of people are very careless listeners and readers, and it is not for the small minority who are really exact in these matters that one has to write. Moreover, it is a great help to clearness of thought and expression to keep before one always an ideal audience of people who will certainly misunderstand every single sentence about which any misunderstanding is in any way possible, and some others as well.

In attempting to think out or to discuss any question, whether it be technical or non-technical, in fact, as long only as it is non-political, the first necessity is probably a knowledge of the question itself; and not only this, but also a proper understanding of its whole environment. This knowledge must be of such a kind as to distinguish what parts of it are important, what parts of it are unimportant, what parts can be described in two sentences, and what others may require as many paragraphs; what parts affect the result but little, however large they seem; and which ones must be considered vital, although their very existence is difficult to discover. The faculty which enables a man to handle his knowledge in this fashion may be summed up in the single expression, "sense of proportion." Moreover the knowledge, to be of real value, must be as totally free from prejudices and prepossessions as in the most rigorous branch of pure science, and as thoroughly imbued with a healthy spirit of scepticism.

One is accustomed to think of engineering work as mainly constructive. But after all, it is quite as much critical. In almost every department of mechanical work there are half-a-dozen ways of solving any particular problem. In some fashion or other the engineer must be able to judge between these various methods, methods which are often very much alike, but each of which may possess certain particular advantages and certain particular drawbacks. The arithmetical criticism which merely counts the advantages and the drawbacks, and puts an equal number of the one against an equal number of the other, is common enough, but obviously useless. The very first necessity to the critic is that he should have what I have just called the sense of proportion, a sense which will enable him to distinguish mere academical objections from serious practical difficulties, which shall enable him to balance twenty advantages which can be enumerated on paper by one serious drawback which will exist in fact, which will enable him in fact to place molehills of experience against mountains of talk. It is perhaps a doubtful point how far this sense of proportion can be taught at all. No doubt it can only be built up upon some natural basis. I am sure that in engineering we all know men whose judgment as to whether it was advisable to take a particular course we would accept implicitly, because we know that it is based on large general criticism, in spite of the most elaborate and specious arguments against it set down on paper. Any third-year student—not to go still farther back—can criticise perfectly along certain very narrow lines, just as anyone can learn the rules of harmony and can write something in accordance with them which purports to be music. But after all the music may be music only in name, and the criticism may not be worth the paper it is written upon, however formal it may appear to be, unless the writer is thoroughly imbued with a sense of the proportionate value of the different points which he makes. To take the commonest possible case, I dare say we have all of us heard certain methods, mechanical, chemical, or other, stigmatised as totally wrong and absolutely useless because they contain certain easily provable errors. I am sure, too, that most of us could give illustrations of cases in which this has been said with the very greatest dogmatism when the errors of the impugned method are not one-tenth part as great as the equally unavoidable errors of observation in the most perfect method.

Probably the best special education in proportion which a man can have is a course of quantitative experimental work. I say quantitative with emphasis, as meaning something much more than mere qualitative work. Here, I think, comes in the usefulness of the engineering laboratory. We require that the training should be not only in absolute measurement, but in relative measurement, the latter being quite as important as the former. Many kinds of measurements stand more or less upon a level as a training of the faculties of observation in themselves, but no single kind of measurement is sufficient as a training in proportion. A year spent in calibrating thermometers or galvanometers might make an exceedingly accurate observer in a particular line, but it would not give the observer a knowledge of what even constituted accuracy in other directions; for accuracy is a relative and not an absolute term. In most engineering matters the conditions are, unfortunately, of a most complex kind; so complex that our problems are incapable of any solution sufficiently exact to satisfy the mathematician or physicist. The temptation to treat these problems as the mathematician treats those with which he deals—namely, to alter the assumed conditions, in order to get an exact solution—is a very strong one. I am afraid it is most strong often in those engineers who are the best mathematicians. It is a temptation, however, steadily to be resisted. We must assume our conditions to be what they actually are, and not what we should like them to be; and if we cannot obtain an exact solution of our problem with its actual conditions, so much the worse for us, not so much the worse for the conditions. Our first duty is generally to find out the conditions; if they are disadvantageous—in fact I mean, and not merely in the problem—to alter them if they can be altered, but not to ignore them because they are inconvenient. We have, then, to find out the extent to which the known conditions permit any exactness of solution at all; and, finally, we have to keep this in view as a measurement of the highest accuracy which is attainable. To work out certain branches of the problem with such minuteness as to give us apparently very much greater accuracy than this is not only useless, but is apt to be positively misleading, as giving an impression of an accuracy which has no real existence.

The relative value of accuracy in different sets of observations is in itself a matter in which a sense of proportion is wanted, and often very badly wanted. Where one has to measure half-a-dozen things of which two are very easily measured and the remaining four are only measurable with great difficulty, it is only human nature that we should spend our energies on getting extremely accurate results with the first two and roughly do our best with the others. It is very difficult under such circumstances to remember that the accuracy of the whole is not the accuracy of the best part of our work, but of the worst.

The extraordinary effect of a want of sense of proportion is nowhere better shown than in the absurd statements which are constantly made as to technical matters in public prospectuses, and the still more absurd statements made in those very numerous documents of a similar kind of which some of us see a great many, but which do not finally emerge into public view. Fortunes are apparently to be made by inventions which, although doubtless ingenious, yet only concern one way of doing a thing which could be done equally well in half-a-dozen other ways. Every one is expected to run after a piece of apparatus which is to save 50 per cent. of something, the total cost of that something, however, being so very small that nobody cares to save it at all. I need hardly mention the all too common case where a contemplated saving of 10 per cent. in the cost of a material works out yearly to an amount much more than equal to the whole cost of the original article.

I believe that experimental work in an engineering laboratory can educate this critical sense of proportion very admirably in a number of ways. In the first place it directs quantitative work into very varied channels, and not along one particular line. Secondly, it compels the observer to combine a number of measurements in such a way that the relative importance of accuracy in each can be seen. In the case of an engine trial, for instance, the combined results are affected by the accuracy of measurements of the dimensions of the machine, by the apparatus and the methods used for measuring the water, by the indicator, and by its springs, by the speed counter, by the thermometers, and so on. An error of 1 per cent. in counting the revolutions is just as important as an error of 1 per cent. in measuring the water, or in measuring the mean pressure. I am afraid that one could point to a good-many cases in which this has been more or less forgotten. Then, by making a series of measurements all in absolute quantities, the relative importance of each quantity to the desired total result can be seen. Thus it will be found that changes in certain quantities affect the total result to a very small extent, while changes in others affect it very largely, so that not only is the accuracy with which different quantities can be determined very different, but also the same degree of accuracy is of very different importance according to the particular quantity to which it refers. Once it is found that a final result is exceedingly little affected by a particular set of changes, it ceases to be of importance to measure or observe those changes in any extremely minute way, and of course the reverse holds equally good. Finally, and this perhaps is the most important matter of all, measurements in such a laboratory are made to a great extent under the complicated conditions under which the actual final result has to be obtained in practical work. They are not made under the conditions which ensure the greatest individual accuracy of each result.

It will be seen that throughout, but particularly in the two last points which I have mentioned, the work of an engineering laboratory is in intention and in essence different from that of a physical laboratory. The aim of the latter is to make its problems as simple as possible, to eliminate all disturbing elements or influences, and to obtain finally a result which possesses the highest degree of absolute accuracy. In most physical investigations the result aimed at is one in which practically absolute accuracy is attainable, although attainable only if infinite pains be taken to get it. It is the business of the physicist to control and modify his conditions, and to use only those which permit of the desired degree of accuracy being reached. In such investigations it sometimes becomes almost immoral to think of one condition as less important than another. Every disturbing condition must be either eliminated or completely allowed for. That method of making the experiment is the best which ensures the greatest possible accuracy in every part of the result. The business of the engineer, on the other hand, is to deal with physical problems under conditions which he can only very partially control, and the conditions are a part of his problem. He does not, for instance, experiment with a steam engine so made that it can work with a Carnot cycle. It is in the nature of the case that he must experiment with a much less perfect machine. In burning fuel he does not use apparatus specially made to absorb the whole heat of combustion, but in the nature of the case has to investigate the behaviour of apparatus in which a very large part of that heat is unavoidably wasted. So one might go on through an immense number of instances. Perhaps the whole matter may best be summed up by saying that in a physical laboratory the conditions of each experiment are under the control of the experimenter, and are subservient to the experiment itself. In an engineering laboratory the conditions form part of the experiment. However much more difficult or complicated they render it, they still unavoidably form part of it—an experiment under any other conditions, or with those conditions removed, would *ipso facto* be irrelevant.

A critical training in matters mechanical is, however, only too similar to the celebrated training of the Mississippi pilot which so nearly broke the heart of Mr. Mark Twain. Whenever the whole matter seems to be completely mastered from one point of view, it is only to find, with a little more experience, that from another point of view everything looks different, and the whole critique has to be started afresh. Machines cannot be finally criticised—that is to say, they cannot be pronounced good or bad—simply from results measurable in a laboratory. One wishes to use steam plant, for instance, by which as little coal shall be burnt as possible. But clearly it would be worth while to waste a certain amount of coal if a less economical machine would allow a larger saving in the cost of repairs. Or it might be worth while to use a machine in which a certain amount of extra power was obviously employed, if only by means of such a machine the cost of attendance could be measurably reduced. In fact, what may be summed up in the phrase the "worth-whileness" of economies, is in itself a matter on which a whole paper might be written. Unfortunately, the latter points which I have mentioned are just such as cannot easily be measured in laboratory work, or, indeed, in any other way whatever, except by actually using the apparatus in question. All that can be said is that a careful training in the critical measurement of comparatively simple points fits a man more than anything else to gauge accurately the importance of such other matters as I have mentioned. No doubt there are many men in whom the critical faculty is insufficiently developed to allow them ever to be of use in these matters, but to those who are intellectually capable of the "higher criticism" it must be, I think, of inestimable benefit to have had a systematic training in the lower.

Is there, then, any general standpoint from which mechanical criticism can be directed? Certain points are obvious, but probably the whole matter cannot easily be generalised. A city has to be supplied with water; there are three requisites—that the water should be of proper quality, of sufficient quantity, and that it should be brought in at a reasonable cost. But in such a case the first two are so enormously more important than the third, that the ideal is comparatively simple—of course, this is quite a different thing from being simply reached. A city has to be supplied with electric light: the essential conditions are similar. But in this case there are so many qualities which are equally proper, and there are so many different ways of bringing it in in sufficient quantity, that the third point — namely, the cost — becomes especially important. A factory has to be driven by steam power; the amount of power that is wanted can be produced by so many different types of engine and boiler—all capable of approximately equal economy, and all claiming equal freedom from breakdowns—that the choice is a peculiarly difficult one from the critical point of view.

It seems almost impossible that a criticism on any one basis could meet all the three cases which I have supposed, unless that basis were that the thing supplied should be the absolutely fittest, having regard to all the conditions of each case and the relative importance of each condition. Possibly in all cases we could get at some generalisation which would show us which was the absolutely fittest, if only the necessary data were in any way complete, which they very seldom are. Perhaps in one sentence we may say that that scheme, or system, or machine, will be the absolutely best in any particular case which will the longest survive and maintain its place in its particular environment. I cannot doubt that this development of Darwinian ideas in the world of the inorganic is a legitimate one. Of course the problem would be comparatively easy in each particular case if only the environment would stand still. It would even be comparatively easy if we knew how the environment was going to alter, but this we are unable to do. We only know that it certainly will change, and will go on changing, and that therefore the things which we make now have not got to survive in the conditions in which we make them, but have got to survive through some new sets of conditions of which we know nothing. I do not think the difficulty is in any way met by the popular method of guessing at what will be wanted fifty years hence, which generally means simply guessing at something very big. It is of no use making our ships or our engines of a type which we choose to imagine will be that of fifty years hence. If we do they will be of no use to-day, and for that very reason they will not even be in existence, useful or other, at the end of the fifty years. Sufficiently sad illustrations of this will occur to every one in very different directions. I hope I shall not be considered churlish in saying that I do not think that the men who have worked on this principle have really been far-seeing, or have really brought us much forward. They have been men often of genius, often of great personal fascination, always of immense imagination. But they have proceeded by methods essentially opposed to anything like the gradual evolution which must occur in technical as it does in natural matters, and in too many cases the results of their labours have not even been giants, but only monsters.

As to what causes one thing to survive rather than another we can only speak very generally. Mere survival may come about by the accident of a peculiarly tough constitution. A few engines built in the time of James Watt are still to be found at work in our own day, but can no more be taken as the fittest type than some solitary megatherium would be who, having outlived all his contemporaries, was able in after ages to look down upon his pigmy and short-lived successors. Mere length of life in such a case may be a mere accident, and is not itself a proof of fitness. We have it thrown at us every now and then that our engines now-a-days do not last like the old ones, as if the mere existence of a very old machine were a proof of its virtues. It is certainly a proof of the excellence of its construction—or, as one may say, of its constitution—and perhaps also of the very small amount of work it has done in proportion to its life and its dimensions.

It is sometimes, I am afraid, rather humiliating to have to remember that, to a very great extent, the question of the fittest, so far as it affects us, is a financial one. In manufacturing processes efficiency and economy tend to survival because they lead to decreased cost of production. In structures or other large permanent works those types tend to perpetuate themselves which require the least material—that is, in which the material used is disposed to the best advantage—and in which the outlay on labour is also smallest, assuming, of course, equal fitness in other respects. There is, no doubt, at present a tendency to dispute this altogether, and to treat all reductions in cost of labour as disadvantages, unless, indeed, the labour be very highly skilled, in which case its remuneration must necessarily be brought down for the sake of equality. I imagine this tendency will last exactly as long as the faithful can get some other people to pay the increased cost, and will thereafter determine itself somewhat suddenly. It can no more stand in the way of natural progress in engineering matters than could the somewhat similar outcry against the introduction of machinery into manufactures two generations ago. It would be as wise to paint a generation of cats green, in the hope of compelling natural selection to work along new lines.

I think we may fairly assume, therefore, that efficiency and economy are both legitimate criteria as to ultimate fitness, and will remain so. Moreover, they are both matters in which measurements can be made, and as to which judgment can be guided by such measurements. But there are other characteristics, not directly measurable, by which we can in some degree form an opinion as to the ultimate fitness of things or processes.

One set of considerations which has great critical importance is summed up in the word simplicity. This does not mean fewness of parts. Reuleaux showed long ago that with machines there was in every case a practical minimum number of parts, any reduction below which was accompanied by serious practical drawbacks. Nor is real simplicity incompatible with considerable apparent complexity. The purpose of machines is becoming continually more complex, and simplicity must not be looked at as absolute, but only in its relation to a particular purpose. There are many very complex-looking pieces of apparatus in existence which work actually so directly along each of their many branch lines as to be in reality simple. I believe it almost always happens that the first attempt to carry out by a machine a new purpose is a very complicated one. It is only by the closest possible examination of the problem, the getting at its very essence, that the machine can be simplified, and this is a late and not an early stage of design. If a mechanical problem is really only soluble by exceedingly complicated apparatus, it generally becomes a question whether the solution is worth having. There is no impossibility in making a machine that will do anything. But the very simplest possible form of apparatus which would wash our hands for us in a suitable manner is probably so very complicated that for many years to come at least that operation will be performed by manual labour.

Very closely allied to simplicity is what I may call directness. In nearly all mechanical processes certain transformations are unavoidable. In many mechanical processes, as I have recently had occasion to mention, a very large number of transformations is at present practically unavoidable. I myself cannot help thinking that probably one of the most distinct signs of fitness is a reduced number of transformations, the bringing of the final and the initial stages as close together as possible, and cutting out altogether the apparently worthless middle processes. But any generalisation of this kind must be very cautiously handled; these apparently useless processes are no doubt in certain cases as indispensable as is the much-abused middle-man in matters economic.

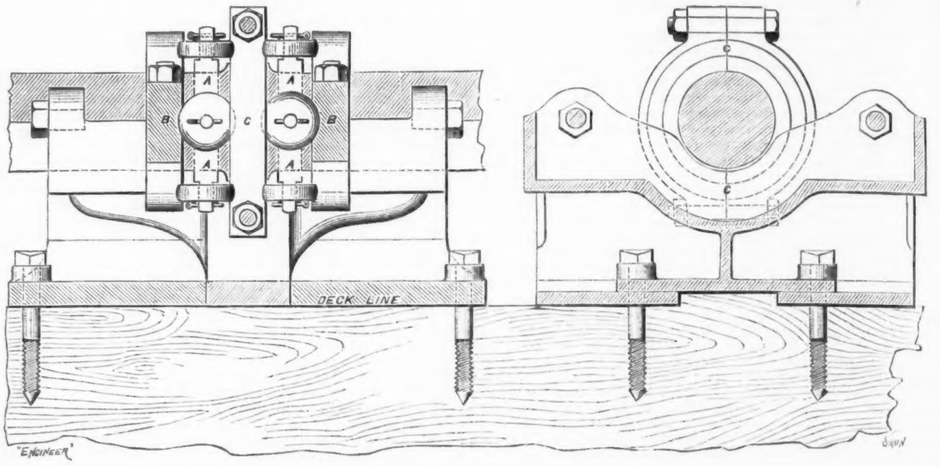
In a critical view of any case where similar results are aimed at by hand work and by mechanical means, it is important to recognise that the similarity of result should very seldom become identity. In the first machine to do anything mechanically which has before been done by hand, the error is often made of trying to imitate the hand-work rigorously. The first sewing machines were, I believe, made to stitch in the same way as a seamstress. It was not until a form of stitch suitable for a machine, although unsuitable for hand, was devised that the sewing machine proved successful as a practical matter. In another but analogous line too, you may remember that the first railway carriages were practically stage coaches put upon trucks, from which the present carriages have only very slowly been evolved.

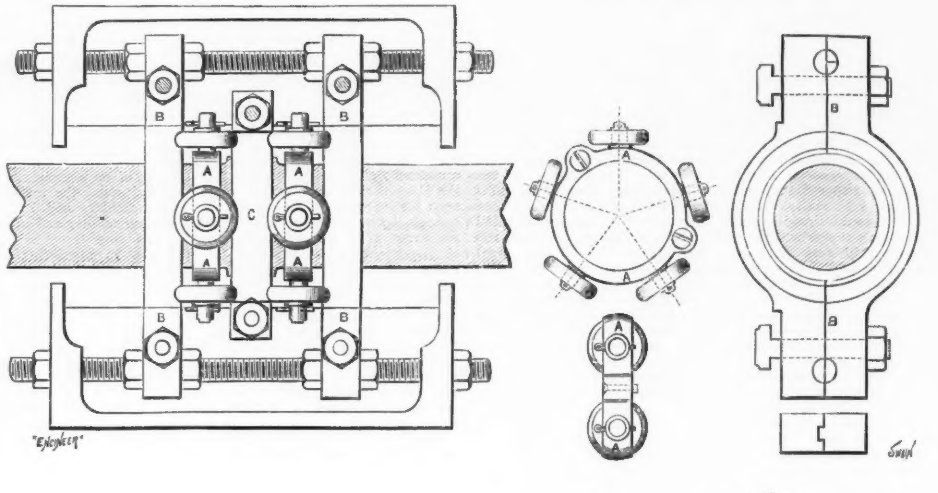
The critic has also to remember that very often the attainment of some very unimportant point, or point of which the importance has been greatly exaggerated, is made the reason mechanically for very great complication. The question of proportion comes in here again, and it has to be considered in any particular case whether the academically perfect machine, which is also extremely complicated, is not inferior to the almost equally good machine which has been constructed in a practicable shape—it almost always is so.

I have endeavoured in my remarks to indicate what appears to me to be the attitude of the engineer towards a very large portion of the work which comes into his hands. In order to deal with the work it is necessary for him first of all to have a certain definite knowledge of "things," that is to say, both of the various subjects which form part of the curricula of all technical schools, and of the further matters which form, as it were, his professional alphabet. These last he learns not from books or lectures as a student, but by example and attempt, as does an artist. Of this part of his training I have said nothing; it has been perhaps sufficiently talked about of late years, and there is little to say which I could have made interesting to a general gathering like this. I cannot leave it altogether, however, without dealing with one matter. Exceptional men are all-round mathematicians or physicists, still more exceptional men are both; but for ordinary folk the study of one side of mathematics or of a single branch of physics is the work of a lifetime. The engineer is bound to know his own profession, by hypothesis, and it is in itself no small matter. Yet in addition he must know some mathematics, some physics, some chemistry, even also some geology, if he is to take any high rank in it. It is, therefore, surely in the very nature of things impossible that he should be a great mathematician or a great physicist, or should devote as much study to those most fascinating sciences as if they themselves were the work of his life. Therefore I beseech my friends of Section A to do what they can to modify their natural attitude of superiority—even of contempt—towards us, especially when we are students. The young engineer—I speak as a member of the great majority of the ordinary kind—would probably never have chosen his profession if he had had special aptitude for mathematical work. Having chosen it, he has to look at mathematics simply as a tool, a means to an end, not an end in itself. I cannot myself see that this point of view is one disrespectful to the parent of all the sciences, and I am confirmed by the knowledge that one or two of the greatest mathematicians in the country are of the same opinion and have the courage to act on it—with infinitely beneficial results to the young men they have to deal with. But I know that to mathematicians in general—the physicists are not so bad—the very name of engineering student is odious, indicating only a man who wilfully refuses to make mathematics his first subject, and who, therefore, deserves neither consideration nor quarter, to whom it is privilege sufficient that he should be allowed to pick up such crumbs as he can digest from a table prepared for his betters. I humbly protest that we deserve better treatment. It is no doubt a great misfortune to us that we cannot afford to spend our training time preparing for examinations, and that we have been compelled to choose for our future a career in which mathematics plays only a secondary part. It is our further misfortune that we have to solve twenty real live problems, each demanding a real live answer, for every single one which otherwise we would have worked out on paper. Perhaps it is also our misfortune—or it may be only our thick-headedness—to believe that in consequence of this we are quite able to judge for ourselves what units it is most convenient for us to work in, what nomenclature satisfies our requirements, and that we are as capable of getting our "*g*'s" in their right places as even some of our distinguished critics. But this is the end of the nineteenth century: philanthropy fills our breasts. May not our misfortunes call out some pity, and not alone contempt? In spite of solemn warnings—which I have lately received in the Press—against the monstrous idea that a presidential address should contain any individual opinions, I venture to repeat here what I had lately an opportunity of saying before a Royal Commission, that in cases where a University or University College takes in hand the preparation of engineers—and I hope that such cases will grow in number—they should provide for them special training in mathematics, and probably also in physics, distinct from the general training in these subjects most suitable for Degrees. I say this with the full knowledge that I may be accused of wishing to degrade the purity of scientific work, and at the same time with the full knowledge that I have no such wish. On the contrary, this special training is the only means by which the rank and file of us will ever know any mathematics at all. And I can say from my own knowledge that if only we can be made what I may call mathematically articulate beings, we shall be able to repay the kindness by placing before the man of pure science problem after problem of transcendent difficulty, of immense interest, and having no single drawback whatever except that its solution may really be "useful," and, after all, this need not be brought too prominently under his notice.

This digression has turned out a long one. I have only further to say that my main object in this address has been to indicate, as well as I could, the general attitude which the engineer must of necessity take up towards much of his work—the point of view from which he must look at it. I shall be extremely glad if anything which I have said should cause this attitude—this point of view to be more clearly kept in mind in the period of training than probably has been hitherto the case.

# WILKES AND EDWARDS' THRUST BEARING





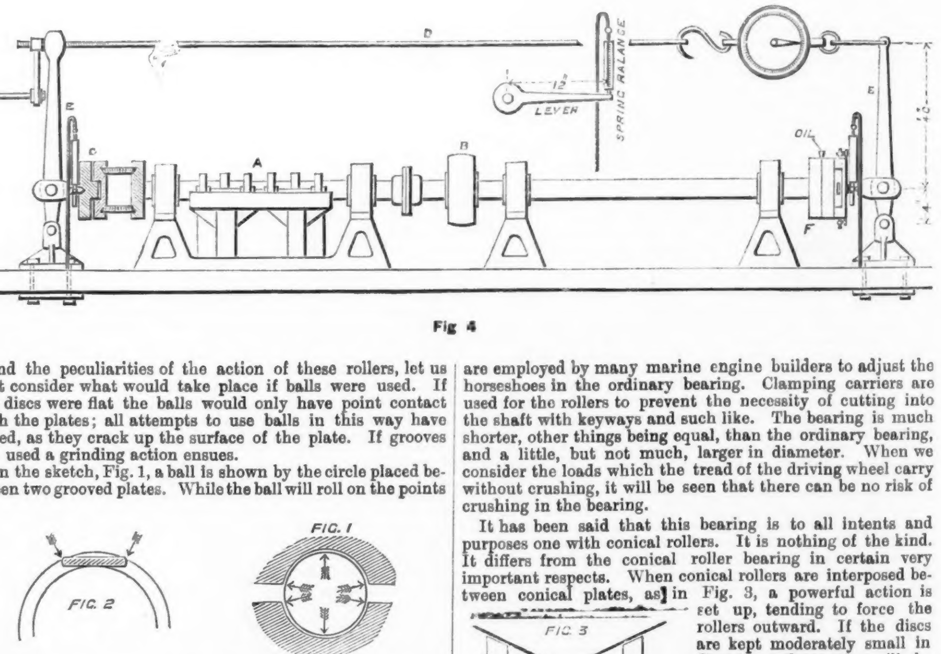


Fig 4

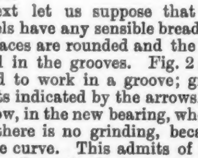
## WILKES AND EDWARDS' THRUST BEARING.

During the recent meeting of the Institution of Naval Architects, the thrust bearing illustrated above was shown at a small local marine exhibition held in the town. The bearing attracted some attention, but not nearly as much as it deserves.

All our readers are no doubt aware that in the early days of screw propulsion much trouble was experienced—and many devices invented and patented to get over the trouble—with the thrust blocks or bearings of screw shafts. Finally, the modern horseshoe system was evolved, and is now universally used, not because it is the best in the abstract, but because it lends itself best to the working conditions. It need scarcely be added that friction rollers placed between discs were tried, and balls revolving in grooves. Any one glancing at the engravings we give will say that we have merely illustrated one of these old devices. That the scheme was very old was our own conclusion when we first saw the model. Careful examination soon proved, however, that the bearing is entirely novel in essentials. It is mainly the invention of Mr. Wilkes, an American engineer, but certain additions have been added by Captain Edwards, R.N., Gloucester Lodge, Portswood, Southampton, and the English patents have been secured in the names of both.

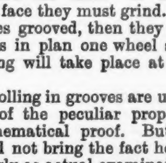
Essentially, the arrangement consists of a series of grooved discs C, secured on the shaft; of similar discs B, secured to the bearing or plummer block, and of certain very peculiarly shaped rollers interposed between the two. Unfortunately, it is has been beyond the power of the engraver to show on a small scale the curves to which the periphery of each roller is turned. There are two curves, each of which is a Schiele's tractrix, or rather a portion of one. The shallow grooves cut in the discs fit the rollers. In order to understand the peculiarities of the action of these rollers, let us first consider what would take place if balls were used. If the discs were flat the balls would only have point contact with the plates; all attempts to use balls in this way have failed, as they crack up the surface of the plate. If grooves are used a grinding action ensues.

In the sketch, Fig. 1, a ball is shown by the circle placed between two grooved plates. While the ball will roll on the points represented by the solid arrows, it is evident that it must grind at the points marked by the dotted arrows. It cannot possibly be in rolling contact with every portion of the groove.



FIC. 2

FIC. 1



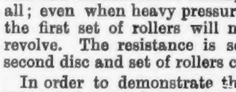
Next let us suppose that wheels are used. If these wheels have any sensible breadth of face they must grind. If the faces are rounded and the plates grooved, then they will grind in the grooves. Fig. 2 shows in plan one wheel supposed to work in a groove; grinding will take place at the points indicated by the arrows.

Now, in the new bearing, wheels rolling in grooves are used, but there is no grinding, because of the peculiar property of the curve. This admits of mathematical proof. But all the mathematics in the world would not bring the fact home to the mind of the engineer as clearly as actual examination of the bearing. Our drawings have been prepared from a bearing which has been at work for nine months in a Southampton tug boat. The discs and rollers we have examined, and we can vouch for the fact that there is not the least symptom of wear, the tool marks being still apparent. The surfaces are ordinary steel, and soft enough to admit of being easily turned or bored.

The drawings are so clear that we do not think any special description is needed. In order to moderate the pressures on the surfaces, two sets of discs and two sets of rollers are employed, the screws at the sides of the bearing being employed to distribute the load equally; just in the same way these screws are employed by many marine engine builders to adjust the horseshoes in the ordinary bearing. Clamping carriers are used for the rollers to prevent the necessity of cutting into the shaft with keyways and such like. The bearing is much shorter, other things being equal, than the ordinary bearing, and a little, but not much, larger in diameter. When we consider the loads which the tread of the driving wheel carry without crushing, it will be seen that there can be no risk of crushing in the bearing.

It has been said that this bearing is to all intents and purposes one with conical rollers. It is nothing of the kind. It differs from the conical roller bearing in certain very important respects. When conical rollers are interposed between conical plates, as in Fig. 3, a powerful action is set up, tending to force the rollers outward. If the discs are kept moderately small in diameter, the angle will be very sharp unless the rollers are also very small. The effect is that a heavy stress is put on the axes holding the rollers in, and much friction is set up at the points A A between the roller and the nut which retains it in place. In the Wilkes and Edwards' gear there is absolutely nothing of this kind, the resistance offered by the whole thrust block to rotation being exceedingly small. We have ourselves seen one disc laid flat on a table, then a set of rollers, then another disc and another set of rollers, and a third disc placed over all; even when heavy pressure is placed on the top disc only the first set of rollers will move, if the disc be caused to revolve. The resistance is so small that the inertia of the second disc and set of rollers cannot be overcome.

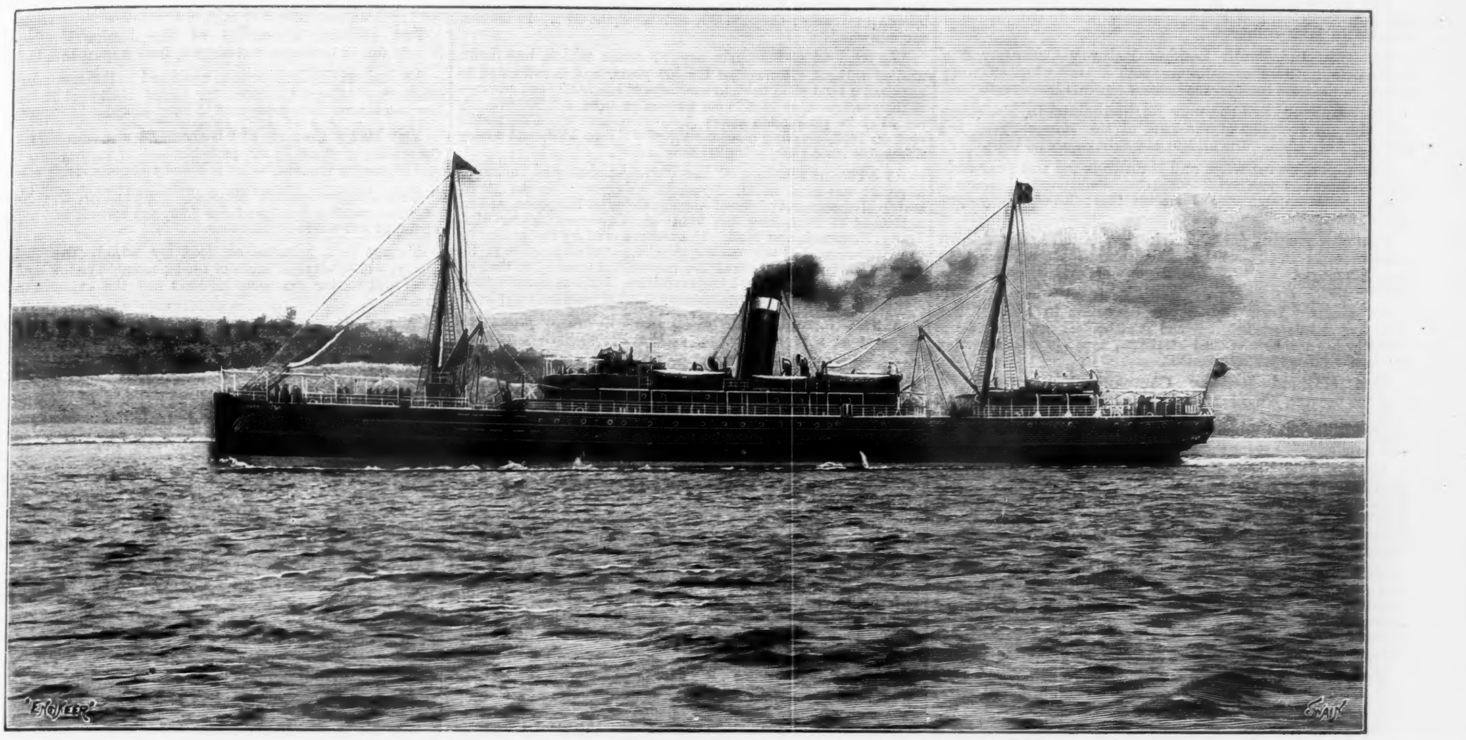
FIC. 3



In order to demonstrate the absence of friction, Captain Edwards has fitted up an ingenious arrangement. A piece of horizontal shafting A, Fig. 4, working in bearings is driven by a belt from an electric motor at any speed from 400 to 800 revolutions per minute. One end of the shaft is fitted with a brass disc F, which bears against another of the same size. The faces have been very carefully finished, and lubrication is perfect. Besides this, the discs are provided with a water jacket to keep them cool. The second disc is also mounted on a short length of shaft. When the two are pressed together the first tends to turn the second with an energy which is measured by the pressure and the coefficient of friction. The

# TWIN-SCREW STEAMSHIP DUKE OF YORK

MESSRS. DENNY BROTHERS, DUMBARTON, BUILDERS AND ENGINEERS



revolution of the second disc is prevented by an iron arm about a foot long, to the end of which is hooked a Salter's spring balance, as shown in the detail side elevation; we have thus the equivalent of a prony brake. At the other end of the first-mentioned shaft is fitted a Wilkes and Edwards' thrust bearing A, with two sets of rollers. This tends to cause the revolution of a short piece of shafting, which is in its turn restrained by a spring balance. A pair of vertical levers, E E, with lathe centres, can be caused to set up a compressive stress through the whole system. With a load of 1000 lb. on the lathe centres, a velocity of 800 revolutions can be kept up for about one minute, the pull on the brass disc spring balance, amounting to about 20 lb., the variations lying between 19 lb. and 21 lb. during the experiment we made. If the run exceeds a minute or so the bearing becomes overheated, in spite of the lubrication and the water. But at the other end C, where the roller thrust is, there is no heating, and the resistance never exceeded ½ lb., or $\frac{1}{40}$th of that of brass disc thrust.

We first examined the invention, certain that there was nothing in it; the facts have made us alter our opinion, and we are persuaded that the bearing could be used with very great advantage in torpedo boats and fast craft of all kinds of moderate dimensions. Whether or not constructive difficulties may limit its application to comparatively small sizes we are not prepared to say, because we have not considered the question. For shafts up to, say, 6in. in diameter, and speeds of 400 to 500 revolutions per minute, we have no doubt at all that the invention is eminently suitable.

## THE STEAMSHIP DUKE OF YORK.

AT various times and in various ways we have directed attention to the efforts made by railway companies to improve the means of communication between England and Ireland. More has been done as regards Dublin than other cities. However, the growing importance of Belfast, which has a greater number of houses than Dublin, and is of very much greater importance as a manufacturing centre, has stimulated effort. Until comparatively a recent period the Belfast merchant travelling to London, Liverpool, or Manchester found it better on the whole to proceed by rail to Dublin, and thence take either one of the London and North-Western Company's fast boats, such as the Violet or the Banshee, or go on to Kingstown and cross by the mail. The extension of the Lancashire and Yorkshire Railway to Fleetwood, and the construction of proper piers and landing stages and a suitable railway terminus, worked a change for the better, and so for several years a fairly satisfactory steamship service has been carried on between Belfast and Fleetwood—a distance of about 110 knots. Recently, however, it was resolved to improve this service, and Mr. Aspinall, chief mechanical engineer of the Lancashire and Yorkshire Railway, proposed a scheme, which has been worked out by Messrs. Laird with the Duke of Clarence, and by Messers. Denny Brothers, of Dumbarton, in the sense that they have designed and built the fine steamship and her machinery which we illustrate this week.

The Duke of York is a twin-screw fast steamer—19 knots. She is owned as regards two-thirds by the Lancashire and Yorkshire Railway Company, and as regards one-third by the London and North-Western Company. She is a sister ship to the Duke of Clarence, built by Messrs. Laird.

State room accommodation is provided for 230 first-class passengers, and steerage apartments for a proportionate number of third-class passengers, together with drovers' room, and complete equipment for officers, firemen, and seamen. The state rooms are of a very superior type; there is plenty of space in them, spring mattresses, and excellent ventilation. The principal saloon is a very handsome apartment, fitted with light woods, much in the same way that the saloon of the Scot has been treated. Wood carving has been used in profusion, and this has all been made in Messrs. Denny's own works. It is of an unusually artistic type, and is somewhat remarkable for the method of production. The design is first drawn on the wood by the artist, and all the rough work is executed by electrically-driven "routers." The wood next passes to the skilled artistic carver, and is by him finished. The cost is reduced in this way, while the objectionable stiffness of machine work is entirely avoided. All the work in the ship is from first to last "thorough."

The propelling machinery consists of two sets of triple expansion engines. The high-pressure cylinders are 23in. diameter, the intermediate 35½in., and the low-pressure cylinders 53in. The stroke is 33in. The engines drive four bladed propellers, 10ft. diameter, at 155 revolutions per minute. The boiler pressure is 160 lb. Steam is provided by two double-ended boilers. Fans are provided, sufficiently powerful to give ¾in. water pressure in the stokeholds, but less than this suffices to keep the pressure. The dimensions of the boilers are given in the table.

The whole of the machinery is a very excellent piece of work, utilised to the best advantage by the chief engineer of the ship, Mr. David Hayes. The frames are of carefully selected cast iron, not steel. The position of the condensers is peculiar. They are, as will be seen from our drawings, carried high up in the wings on brackets. The shaft tunnels are very roomy. The ship is lighted throughout by electricity, the engines and dynamos being carried on the middle platform, extended under the deck aft for the purpose.

The steering gear is Browne Brothers' patent, being similar to that in the Scot. The engine is carried on the end of the tiller, and traverses by the aid of a steel-toothed quadrant bolted to the deck. No covering has been provided, the whole of the working gear being enclosed in water-tight casings. Instead of a deck-house, there is a rail or fence all round.

We recently made the trip from Fleetwood to Belfast and back, and hasten to bear testimony to the courtesy of Captain Cook, in command of the ship, a gentleman whose experience of the Irish Channel extends over thirty years. The trip across was made at a very high speed without event. Coming alongside the wharf in Belfast, the port screw unfortunately caught a very flexible fine strand wire rope used as a warp, and wound up about thirty turns on the boss. A diver was at work all day, but could not get it clear. The rope did not foul the propeller in a way to prevent it from rotating, the rope being cut by the diver. It was feared, however, that if the port engine was used the rope might wear off the Muntz metal nuts of the stern gland, and so, after consultation, it was resolved to make the return trip to Fleetwood with the starboard engine only. This was vexatious, because the boat started at 9.30 p.m. on the night of the 11th of July, and was crowded with passengers availing themselves of the holiday which commences on the 12th July in Belfast, and appears to last a week. On a previous occasion the trip had been made with one screw for experimental purposes, but the screw was allowed to revolve, and an average speed of 15 knots was attained. In the present case, if the screw was allowed to turn, it might just as well be used to drive the ship. Its revolution was prevented by putting the port engines in back gear. The ship had then to drag a four-bladed screw through the water, and carry a port helm to keep her head straight. Yet, with all this drawback, she made nearly 13·5 knots. The screw was cleared next day at Fleetwood by a diver. In all respects she is a very splendid ship, and remarkably free from vibration. In fact, she is a most comfortable boat. Passengers can now leave London at 5.30 p.m., and Manchester at 9.50 p.m., arriving at Belfast about 6 a.m. the following morning, whilst under the old conditions of train and steamboat services, the times of departure from London were 2.10 p.m., and Manchester 7 p.m., arriving at Belfast at the same hour. Practically an equivalent saving has been effected on the return journey. The Lancashire and Yorkshire Railway Company, as the larger owners, work the service of trains in connection with these steamers over the Preston and Wyre line between Preston and Fleetwood. The railway companies' Belfast steamers at Fleetwood depart and arrive alongside the railway station, from which a covered gangway, with hydraulic lifts for luggage, is provided, no charge being made for porterage to or from the steamers. The sailings from Fleetwood and Belfast are 11.50 p.m. and 9.30 p.m. respectively, so that the sea passages are effected wholly in the night time.

The principal dimensions of the ship and her engines are given in the accompanying table:—

| | |
|---|---|
| Length between perpendiculars | 310ft. |
| Breadth of beam, moulded | 37ft. |
| Depth, moulded | 17ft. |
| Height between main and lower decks | 8ft. |
| Height between upper deck and poop bridge and forecastle decks | 8ft. |
| Indicated horse-power | 4000 |
| Speed | 19 knots |
| Boiler length | 21ft. 1½in. |
| Boiler diameter, mean | 14ft. 6in. |
| Grate surface for two boilers | 270 sq. ft. |
| Heating surface, tubes | 7653 sq. ft. |
| Heating surface, flues | 1530 sq. ft. |
| Total | 9183 sq. ft. |
| Ratio of heating surface to firegrate | 34 to 1 |
| Ratio of firegrate to area through tubes | 5·29 to 1 |
| Total number of common tubes | 956 |
| Total number of stay tubes | 388 |
| Total | 1344 |

## THE UNITED STATES TARIFF BILL.

IT is very difficult for an Englishman to understand the details of the dispute between the United States Senate, corresponding to our House of Lords, and the House of Representatives. It appears, however, that a Tariff Bill will actually be passed and come into operation at once. The following is a statement showing the reductions made by the Senate Bill in the average *ad valorem* duties, as compared with the duties at present imposed under the M'Kinley Law:—

The duties on painted china are reduced from 60 per cent. to 35 per cent.; on plain china, 55 per cent. to 30 per cent.; on manufactures of glass, 60 per cent. to 35 per cent.; pig iron, which paid from 26 per cent. to 41 per cent., will pay from 15 per cent. to 21 per cent.; the duties on iron ore are reduced from 33 per cent. to 23 per cent.; on scrap iron, 48 per cent. to 28 per cent.; on scrap steel, 43 per cent. to 26 per cent.; bar iron, which pays from 25 per cent. to 33 per cent., will pay from 16 per cent. to 32 per cent.; the duties on steel rails are reduced from 58 per cent. to 34 per cent.; on bars of rolled iron, from 62 per cent. to 45 per cent.; on boiler or other plate iron or steel, 54 per cent. to 25 per cent.; sheets of iron or steel—common or black—which pay from 25 per cent. to 70 per cent., will pay from 20 per cent. to 55 per cent.; the duties on tin-plates are reduced from 78 per cent. to 42 per cent.; on tin manufactures, from 55 per cent. to 35 per cent.; the duties on cylinder glass, polished and unsilvered—now 20 per cent. to 64 per cent.—will be from 13 per cent. to 48 per cent.; on plate glass, fluted, &c.—now 49 per cent. to 64 per cent.—37 per cent. to 43 per cent.; on plate glass, unsilvered, cast, &c.—now 98 per cent. to 174 per cent.—88 per cent. to 122 per cent.; the duties on plate glass, cast and silvered, and above 24in. by 60in., are reduced from 49 per cent. to 31 per cent. on cylinder and crown glass, silvered from 44 per cent. to 28 per cent.; steel ingots, &c.—now paying from 29 per cent. to 50 per cent.—will pay from 20 per cent. to 40 per cent.; nails—now 23 per cent. to 45 per cent.—26 per cent. to 30 per cent.; the duty on railway fish-plates is reduced from 72 per cent. to 25 per cent.; screws—now paying 47 per cent. to 111 per cent.—will pay from 33 per cent. to 67 per cent.; the duty on lead sheets is reduced from 37 per cent. to 18 per cent.; on nickel from 23 per cent. to 14 per cent.; on manufactures of metal from 45 per cent. to 35 per cent.; on cotton cloth, not over a hundred threads and not bleached, from 35·17 per cent. to 35·05 per cent.; ditto bleached, from 38 per cent. to 26 per cent.; ditto, dyed, coloured, &c., from 41 per cent. to 30 per cent.; on cotton cloth, exceeding a hundred threads, unbleached, from 42 per cent. to 32 per cent.; ditto, bleached, from 43 per cent. to 38 per cent.; ditto, dyed, coloured, &c., from 44 per cent. to 38 per cent.; on woollen yarn from 278 per cent. to 30 per cent.; and on woollen shawls not about forty cents a pound, from 136 per cent. to 35 per cent.; the duty on blankets—now 80 per cent. to 104 per cent.—is fixed at 35 per cent.; on woollen hats—now 86 per cent.—25 per cent.; on flannels not over fifty cents a pound—now paying 85 per cent. to 104 per cent.—25 per cent. to 35 per cent.; and the duty on silk, partially manufactured, is reduced from 60 per cent. to 20 per cent. Plates of copper, not rolled—now paying 11 per cent.—will be duty free; binding twine—now paying 6 per cent.—will be duty free, as will also oil and water colour paintings and statuary, which are at present liable to a duty of 15 per cent.

## RAILWAY MATTERS.

The Tiumen-Omsk section of the Siberian Railway will be formally opened about the 1st September.

The Great Western Railway Company has decided to begin the construction of a line connecting the Severn Tunnel to Avonmouth Dock at Bristol.

The City and South London Railway Company has decided to institute experiments with a view to substituting motors on the train itself for the present separate locomotive.

The earthworks of the new Bechuanaland to Mafeking line, with the exception of the bank at the Molopo River, are practically complete. The bridges and culverts are all built.

The report on railways and tramways fcr the year ending 30th June last, just issued by the Commissioners for Railways in New South Wales, states that there are 2560 miles of railway open in that colony.

The new graving dock at Grimsby, which has just been constructed by the Manchester, Sheffield, and Lincolnshire Railway Company, at a cost of £60,000, was brought into use on the 1st instant.

An electric tramway, about 3½ miles in length, has been opened between Belgrade and Topscheider. Another electric tramway has also been opened at Baden, near Vienna, connecting the former place with Helenenthal.

The Midland Railway Company has opened its new line between Wincoband and Chapeltown for mineral traffic. The *Contract Journal* says this is part of a more extensive scheme, which will provide a new line between Chapeltown and Barnsley, and give improved communication with Wakefield.

It has now been decided to operate the West Side Elevated Railway at Chicago by electric power. This line connects the western part of Chicago with the main city transit systems. It will be a four-track line for a greater part of the way, so as to allow of an express service. The power is to be obtained from four dynamos.

The City Commission of Sewers have resolved that, in the event of the railway company carrying out such repairs as should render Moorgate-street Station free from danger to the satisfaction of the district surveyor, further proceedings by the solicitor to the Commission be deferred pending the rebuilding of the station.

The work in connection with the Waterloo and City Underground Railway is proceeding on the south side of the river near Blackfriars Bridge. Pile driving has been commenced at this spot, where it is also intended to sink caissons, and eventually construct two tunnels, one going to the Mansion House and the other to Waterloo Station.

Complaints have been made at the Blackpool Town Council of attempts to interfere with the electric light supply and the running of the electric tramway. Conductors had been arranged to run the tramway current to earth, the interference necessitating the appointment of a special watch in order, if possible, to detect the culprits.

An underground railway is fast nearing completion in Paris. The interesting feature of the work, from an engineering point of view, is the manner in which the tunnel was built, a masonry arch being used for nearly the entire length. The line follows the streets, one-half the street being closed in short sections at a time. It will be the first section of a metropolitan system in Paris.

The North British Railway Company has just entered on the work of opening up part of the tunnel at Charing Cross Station, Glasgow, in order to satisfy the public demands, and in consequence of the rejection by the city authorities of proposals for effecting the same object by a series of ventilating shafts. A number of residences on the north side of Elmbank Crescent are being demolished to make way for the extension, which is estimated to cost about £40,000.

The Dortmund, Gronau, and Ensched Railway in Germany has fitted the electric light in its carriages. The supply is obtained from secondary batteries. The cars are fitted with low voltage lamps of 16-candle power in the first-class carriages, and 10-candle power in the other compartments. It is estimated that each lamp-hour costs 2·6d., disregarding the maintenance of the accumulators. The batteries are conveyed to and from the charging station at Dortmund in trucks, running on a narrow-gauge line. Each battery weighs about 460 lb.

According to the report for the half-year ended 31st December, 1893, of the directors of the East Indian Railway, and which was to have been presented to the annuity holders at the general meeting held on 27th June, 1894, the total length of the railway proper remains 1611 miles, of which 474 miles are double and 1137 miles are single. In addition to the above, the Tarkessur Railway 22 miles, and the Delhi-Umballa-Kalka Railway 161 miles, were worked by the company during the half-year, making the total length worked 1794 miles. The mean length worked during the half-year was 1819 miles, the same as in the corresponding period of 1892.

With regard to the probable cause of the recent accident to the Scotch express at St. Pancras, a correspondent states that No. 7 platform, where the express was run in, is one of a series which are not ordinarily used for the main line trains. Before the arrival of the Scotch express on Sunday a long fish train had been standing at the platform mentioned, and the correspondent suggests that the drippings from the trucks had fallen upon the rails and rendered them so greasy that when the brakes were applied the wheels skidded round. George Liddle, the guard in charge of the front portion of the express, stated that the train was not running at a higher speed than from four to five miles an hour when it entered the station. He leaped from his van, as he was afraid there was something wrong, and immediately he had done so the engine collided with the buffer stops and the van which he had just left became a wreck.

In our issue of July 20th we published a letter signed "Scriber." It described some important observations made under considerable inconvenience by a feline member of a dynamical research committee. The experimental observations were, as some of our readers will have observed, made with somewhat incomplete or at all events antiquated apparatus, but nearly everyone will admit that the experiment would have been impossible before the days of railways, and except by the particular combination of muscle, horn, and axle described, could not have been made even now. The line of argument which probably led to the inquiry is not, we see by the remarks in the columns of a contemporary, quite understood or appreciated, although the writer of the remarks has discussed the observed results with all the gravity and seriousness which the records of so great a feat deserve. It is proposed that the technical education committee of the County Councils of the districts in which these daring and original experiments were made should be approached with the object of obtaining a grant of money with which the use of the train for an indefinite period shall be secured and placed at the disposal of the experimenter already referred to. When this has been done such further facts as may elucidate the points not now understood by our contemporaries will no doubt be forthcoming. It may, however, be in the meantime remarked that the further experiments are not likely to alter the method of determination of the stresses per unit of leading claw section.

## NOTES AND MEMORANDA.

The deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 17·6 per 1000 of their aggregate population, which is estimated at 10,458,442 persons in the middle of this year. The highest and lowest rates were: Croydon 9·8, and Liverpool 29·2. In London the rate was 17·4.

We read of a Swedish copper mine which has been worked without interruption for 800 years, and is estimated to have had a total yield in eight centuries of 1,200,000 tons, worth—at the average value of £28 per ton—more than £32,000,000. A record of its production shows that the output was 1336 metric tons in 1633, reaching a maximum of 3445 in 1650, and slowly decreasing since 1690, being 271 tons in 1891.

At a recent meeting of the Paris Academy of Sciences a report was read on M. Bigourdan's memoir "On the Micrometric Measurement of Small Angular Celestial Distances, and on a Method of Perfecting this kind of Measurement," by MM. Lœwy, Tisserand, and Wolf. The method used by the author for the measurement of micrometric angular distances consists in the use of glass points in place of the micrometer threads, so that the image is never blotted out by superposition. It allows of much easier work, and is at least as accurate as any method previously employed.

A new formula for friction head in water pipes was proposed at a recent meeting of the Boston Society of Civil Engineers. It is $I = C' Q^{\frac{11}{10}}$, where I is the friction head in feet per foot, C′ is a coefficient varying with the roughness and the diameter, and Q is the discharge in cubic feet per second. This formula has been deduced from that used by Professor Unwin and M. Flamant by determining from a large number of experiments the proper coefficients for use with both new cast iron and riveted sheet iron pipes. A paper describing the use of this formula, with a number of tables to facilitate its application, will be found in the *Journal* of the Association of Engineering Societies for June of the current year.

A communication made to the Academie des Sciences, by M. Henri Moissan, contains some new and interesting researches respecting the metal chromium. By availing himself of the intense heat produced by the electrical current, the experimentalist succeeded in preparing cast chrome in a very small quantity, which may be fairly represented by the formula C Cr. When treated with lime or the double oxide of calcium and chrome, the metal produced under these conditions is more infusible than platinum, and takes a very fine polish. It is moreover not attacked by atmospheric agents, not to any great extent by acids, and resists the action of aqua regia and of alkalies in fusion. This preparation of chrome leads to some very important results in connection with the alloys of the metal. Alloyed either with alumimium or copper, it possesses some remarkable qualities. When pure copper, for instance, is alloyed with 0·5 of chrome it becomes endowed with a double power of resistance, is susceptible of a high polish, and undergoes less change when exposed to atmospheric influences than when in a condition of purity.

A law recently passed in America provides that no river steamer shall have an externally-fired boiler with shell plates of iron or steel exceeding an average thickness of $\frac{30}{100}$ of an inch, No boiler of this type on such vessels shall have less than 3in. space between its shell and any of its internal flues, and not less than 3in. space between such flues when any such flues are more than 5in. in diameter; and every such externally-fired boiler employed on any such steam vessel shall be provided with a manhole, in the lower part of the front head thereof, of such dimensions as may be prescribed by the Board of Supervising Inspectors, in all cases where the distance between its internal flues is less than 3in. Externally-fired boilers having shells constructed of iron or steel plates not exceeding an average thickness of 0·50in., may, in the discretion of the Secretary of the Treasury, be authorised and employed on steam vessels navigating the Atlantic and Pacific Oceans, or salt water bays or sounds, or the great lakes, or any of them, and water flowing to and from the same, or any of them; provided that in inspection, no plate that is by this Act limited to a thickness of 0·30in., and no plate that is by this Act limited to a thickness of 0·50in. shall be rejected for use if found to exceed these dimensions respectively, if the average thickness thereof does not exceed the limits therein specified, and the amount of steam pressure that will be permitted to be carried in boilers constructed in accordance with the requirements of this Act shall be determined from measurement showing the least thickness of the plates.

A large number of cities obtain their water supply from subterranean water-bearing strata reached by tube wells consisting of iron tubes driven low, and having the upper ends connected to the suction main of the pumping engine. At the city of Lowell the contracting company sank seventeen test wells before locating the permanent plant, and the formation was so irregular that one well might be good, and the next so poor as to require pulling up the pipe. The wells vary in depth from 47ft. to 67ft., the average being 52ft., and all being 6in. diameter. Before the wells were connected and pumped by steam the elevation of the water in each was 9in. above that in the brook, and rose and fell with the latter, the water from the wells always flowing into the brook. The yield from forty-four wells when pumped singly being at the rate of 7,000,000 gallons per day, a test of the wells collectively was ordered, and the supply was found to be 2,000,000 gallons. It was evident that the wells were too near together, and experiments were made to determine which could be cut out without affecting the quality of the water obtained. Finally, twelve wells were removed, leaving thirty-two, from which 2,333,000 gallons have been pumped in twenty-four hours. After adding eighteen wells, 3,000,000 gallons per day were pumped for some time, then alterations were made in the pumping machinery and twenty-two 4in. wells added, making seventy-two in all, from which 3,300,000 gallons per day are now being pumped, with a vacuum of 23in. to 23½in. The water in the outside test wells now shows conclusively that the supply is greater than the draught. In the method of sinking these wells, the pipe is put down by the use of a sand bucket nearly as large as the interior of the pipe and about 6ft. long. The bucket is raised and lowered by wooden rods connected together at the ends, so that when in the well they act as one rod, and make the bucket very efficient in its work. This bucket removes all the material from the inside of the pipe, and when it is sunk in gravel, stones 5½in. diameter have been removed with it. While the earth is being removed, the pipe is gently turned or rocked, and goes down by its own weight. This is a very rapid manner of getting pipe down through quicksand. In very hard gravel the pipe is sometimes driven a little with a heavy wooden weight. If stones too large to come up through the pipe are encountered, they are broken with a large drill, or, if this is impossible, the pipe is pulled up and the location changed. Two "push wells" were also put down. They were constructed by building a strong dam to press against and using a very strong clamp on the pipe. The pipe is pushed into the ground by the use of four jack screws. This is a very slow and expensive way, but allows a very long screen to be placed in a narrow stratum of water-bearing material, and has worked very well at other places, but here the material is not uniform enough to warrant the outlay. They are both good wells, but not enough better than the others to pay the difference in the cost. All the wells are made with the Cook patent strainer, varying in length from 8ft. to 17ft., according to the depth of the water-bearing stratum. The screens in the push wells are one 24ft. and the other 42ft. in length. After the screens are swedged into the well pipe and the well thoroughly pumped and washed by steam, the water is perfectly clear and no sand comes up through the screen. The screens are made from a drawn brass tube.

## MISCELLANEA.

It is stated that the Burma Government has decided to open an Engineering School.

The total number of spindles now used in the cotton mills throughout Japan is said to be about 720,000.

The summer excursion of the Junior Engineering Society will be to Cardiff and district, from August 18th to 25th.

An Industrial Exhibition, confined to the manufactured products of Alsace-Lorraine, the Grand Duchy of Baden, and Rhenish Bavaria is to be opened in May, 1895.

The Town Council has instructed the Southend Pier Committee to report on the probable cost of further lengthening and improving the pier, which is already 1¼ miles long.

The Anglo-Spanish shipbuilding yard on the Nervian at Bilbao receives iron ore at one door, and turns it out as a fully-equipped war vessel at the other.

There is a scheme on foot by which the Colombo sewage will be emptied south of the harbour. The low level of the town will render the work difficult and the expenditure very great.

A large quantity of india-rubber has been exported from Rangoon during the past official year. It is obtained from the forests in the Tanaih Chung districts in Northern Kachin Hills of the Upper Irrawaddy.

The repairing of the old aqueducts of Solomon in Jerusalem will entail the building of a tunnel 3750 metres long, to cost £80,000. The aqueducts will bring the water to Jerusalem from the fountains of Arroul.

A special commission has been nominated in Paris for experimenting with smoke-consuming apparatus. The meeting will be opened by papers from inventors, and a total sum of £380 will be awarded among the best apparatus.

On Thursday evening an explosion occurred at the Rowley-hall Colliery, Staffordshire, owing to men going into a portion of the mine where some gas and damp had previously been tapped. A pitman was suffocated and another man was severely burnt.

M. Janssen has exhibited at the Academy of Sciences the clockwork of the registration apparatus at the Mont Blanc Observatory. It requires winding up only once in eight months, and it is lubricated with a peculiar kind of oil, which only congeals at 80 deg. below freezing point.

There is a rumour afloat that Mr. Maxim's experiments with his flying machine are abandoned. We are desired by Mr. Maxim to state that this is by no means the case, as he is at present looking out for a suitable locality where there is more room than there is at Bexley for the completion of his experiments.

The official trials of the Vizcaya belted cruiser, built for the Spanish Government, were completed last week with satisfactory results. The Government decided to dispense with forced draught on the occasion, in consequence of the excess of speed attained by the sister vessel, the Infanta Maria Teresa. The natural draught speed was 18·6 knots.

Her Majesty's cruiser Blanche has gone into harbour to make good defects to her starboard boiler, which have necessitated her return to England. She has a crack on the inside of her boiler no less than 10ft. in length, the result being that steam could only be raised in it with safety to about 60 lb., whereas the boiler should stand a test of 250 lb. to the square inch.

The Admiralty have decided to strengthen the defences of the river Medway by constructing a boom to bar the passage of the river in case of an emergency. The boom is estimated to cost £6000. The boom, when ready, will be fitted across the river to test its efficacy, and will afterwards be stored in sections for use should an emergency arise. The work has been recommended by the Harbour Defence Committee. The gunboats Banterer and Grappler are to be utilised as portions of the boom.

The Gohna Lake rose 24ft. 6in. last week, and on the 12th inst. was within 57ft. of the top of the dam. Its full length is now 4½ miles, the average width being half a mile. The greatest depth is 720ft. The *Times* says the percolation is very heavy. This, combined with heavy rain, has washed away a large portion of the lower part of the dam, leaving an almost perpendicular drop of 400ft. The section thus displayed shows a layer of boulders on the top, below which is pulverised rock. The lake is expected to overflow within fifteen days.

The authorities at Chatham Dockyard have in preparation a scheme for still further developing the extension works by constructing another basin. Plans are also to be prepared for three new docks, one of which is to be of immense size, and capable of accommodating the largest vessel likely to be built in the future. The need for larger docks is apparent, seeing that at Chatham there is not one of sufficient size to hold the cruisers Powerful and Terrible, provided for in this year's estimates. It is estimated that the total cost of the proposed works will be about £1,500,000.

An Egyptian paper says that out of seventy-four thousand tons of coal landed at Port Said during September, only twenty-four thousand tons came from Wales, the balance being supplied from Marseilles, Antwerp, Glasgow, Newcastle, Dunkirk, Hamburg, Rotterdam and Bremerhaven. It is said that some of the foreign coal has taken such a hold on the market, that it will be some time before the Welsh trade can resume its old position in the Suez Canal. Hitherto the coal stock of Port Said has consisted, as a rule, of about 95 per cent. of Welsh coal. The falling off is the result of the recent coal strikes.

It is not at all certain, the *Times* says, that the Commission of Inventions, as stated by a news agency, "will have nothing whatever to do with M. Turpin's invention." It is true that he has received back his documents, but this, as he told the Commission, was simply in order that he might continue his studies and prepare the specifications for the patent which he was asked to take out. The Commission made M. Turpin two proposals—either to undertake trial experiments itself on its own responsibility, M. Turpin being invited to furnish a definite scheme of experiment, or that he should conduct experiments at his own expense, and invite the Commission to witness them. He has not yet decided as to these proposals.

Owing to the refusal of the pit lads at the collieries in North Staffordshire to accept their share in the 10 per cent. reduction of wages lately agreed to in the Federation districts throughout England, a similar trouble has arisen to that which has developed itself in South Yorkshire. As the pits are unable to go on without the boys' services, many of the collieries have been brought wholly to a stand, and there is this week a general disorganisation of colliery labour throughout the district. The local agents of the Federation are doing their best to bring the boys into a more amenable state of mind, but at present without success. Among the adult miners, too, a great deal of dissatisfaction exists at certain of the pits, owing to the allegation that, at some collieries, more than 10 per cent. is being taken off, and that at others the reduction is being made applicable to engine men and other classes of labour apart from the miners proper.

## TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

W. J. G.—*It is quite impossible to publish everything at once. We have not forgotten your request.*

J. C.—*Our drawing of the Minneapolis illustrates her as designed. The difference between that and the ship as she is consists principally in the funnels. It was intended that she should have four funnels, like the Columbia. In Brassey's "Naval Annual" she is shown with three funnels.*

J. T. H.—*The bulb A in your sketch of a maximum and minimum thermometer is filled with spirit. The space above A ought to be a vacuum, but very commonly it is not. The small amount of expansion and contraction of the thread of mercury due to change of temperature is negligible. It is, of course, possible to make a thermometer of the kind with an air bulb A, but we have never seen one.*

### SUBSCRIPTIONS.

The Engineer *can be had, oy order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

| | |
|---|---|
| *Half-yearly (including double number)* .. .. | £0 14s. 6d. |
| *Yearly (including two double numbers)*.. .. | £1 9s. 0d. |

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

### MEETINGS NEXT WEEK.

Iron and Steel Institute.—Meeting at Brussels, commencing on Monday, the 20th, and concluding on the 24th inst.

Liverpool Engineering Society.—Saturday, August 25th. Excursion to the Wirral Railway Works and Dee Bridge, by the kind permission of the respective engineers, Sir Douglas Fox, M. Inst. C.E., and Mr. Alexander Ross, M. Inst. C.E.

Junior Engineering Society.—August 18th to 20th. Summer meeting at Cardiff.

# THE ENGINEER.

*AUGUST* 17, 1894.

## ENGINEERS AND THE ADMIRALTY.

In the House of Commons on Tuesday night a question was put and a statement was made, the importance and purport of both of which may very readily be overlooked or misunderstood. Mr. Clough asked the Secretary to the Admiralty whether the Admiralty were satisfied with the two first of the forty-two torpedo-boat Destroyers recently ordered; and whether they were taking care to utilise their experience as to details of the Havock and Hornet in the construction of other vessels of the same class. Sir U. Kay-Shuttleworth said in reply:—"The Admiralty are glad to recognise that Messrs. Yarrow have been the contractors who have first constructed and completed with rapidity for the British Navy vessels of the high speed of the Havock and Hornet. On behalf of the Admiralty I am happy to express our satisfaction with the manner in which the contract has been carried out. We are also ready to acknowledge the value which we attach to the designs of Messrs. Yarrow for the machinery of these vessels. Practical proof has been given of this favourable opinion by our use of certain parts of these designs as a guide to contractors for some of the other torpedo-boat Destroyers since ordered." Certain parts are no doubt included in the whole, and so far Sir U. Kay-Shuttleworth's reply is accurate. It is the truth—but not nearly the entire truth. For "certain parts" it is necessary to substitute the words "the whole," in order to arrive at the facts. "Certain parts" may mean all the machinery designs, and if the report which has been much discussed among engineers for now several months is true, all Messrs. Yarrow's working drawings have been freely handed about. This fact we have heard from numerous sources, and is far beyond dispnte. To many, if not to the greater number, of our readers the question and the reply may seem to concern only the firm in question. To those, however, who have watched the progress of events they will present a different aspect. They involve a principle of the very highest importance, and they give utterance to the complaints which have been made hitherto almost in private concerning the dealings of the Admiralty with the engineers of Great Britain. Let us consider what the facts are in the particular case cited. Mr. Yarrow has done at least as much as any other man living to develope the high-speed torpedo boat and the torpedo boat destroyer. Only those who are behind the scenes can form any adequate idea of the labour and money and genius that have been expended to produce such a boat as the Hornet; she is really the result of the arduous labours of many years. The success attained has not been reached by the assistance of professors, or the learning set forth in text-books. It has been obtained step by step by direct, costly, dangerous, and tedious experiment. The knowledge needed to design and construct such a craft is specialised to the last degree; and it is of course embodied in the voluminous working drawings. The Admiralty wanted torpedo catchers of the highest speed, as other nations were fast advancing in this direction. Certain stipulations were laid down as to speed, &c., and Messrs. Yarrow tendered for them. In accordance with the rules of the Admiralty, Messrs. Yarrow sent in during construction a complete set of working drawings for approval. The drawings, be it understood, never became the property of the Admiralty. They belonged to the contractors. They were approved, and the Hornet and the Havock were constructed. The results obtained were, as we have already informed our readers, satisfactory in the highest degree. The Admiralty desired to augment the number of such boats. This was commendable. The method adopted of obtaining them was in the highest degree reprehensible. Messrs. Yarrow's drawings were sent to the North to several firms to show them what was wanted, and to help them to design efficient machinery.

It is not necessary, we think, to dwell on the fact that these drawings contained information which was entrusted to the Admiralty while remaining the property of Messrs. Yarrow and Co. We have already referred to the theft of drawings of torpedo boats, and Messrs. Yarrow offered a reward of £200 for the detection of the thief. We mention the fact now only to emphasise further that this class of drawings, representing special information, is of the utmost value to the owners. It is certain that few of the northern firms could unaided build such a vessel as the Hornet with any hope of complete success unless they carried out for themselves an elaborate and tedious series of experiments. We are sure that the general reader of these pages will be unable to realise fully how enormous are the difficulties to be overcome in getting the last knot out of such little craft. Success or failure turns on apparent trifles—a small mistake in the pitch, diameter, or area of the screw, for instance, may mean disaster. But we believe that we are right in saying that every firm to whom Messrs. Yarrow's drawings were sent fully realised the importance—nay, the absolute necessity—of having them. Thus, then, the Admiralty supplied those who were asked to compete in price with the Poplar and Chiswick firms with all the information that has been acquired with so much expense, trouble, and risk. Commercially it is impossible to imagine anything much more unfair. The defence set up is at once plausible, but unjust. It is simply this: the Admiralty are extremely pleased with the performance of the Havock and Hornet; in the interests of the taxpayer they desire to reduce the cost, and obtain more craft of the same kind at a less price. They ask northern firms who have had no experience in this class of work to tender. Those asked say very naturally that unless they know more it is impossible for them to undertake the work. Thereupon the Admiralty send Messrs. Yarrow's drawings to guide them. Now, it may be said here at once that the Admiralty have a right to utilise for the good of the nation the information they have obtained. That is quite true—under conditions. The French Government pursue the proper course. They specially stipulate in their contracts that they shall have a right to utilise the drawings or other information supplied by contractors; and the contractors go into the matter with their eyes open. But the matter does not end here. If, for example, M. Normand designs engines, a boiler, or a boat, and M. Normand's drawings are supplied to another firm which works to these, then M. Normand is paid a royalty, or percentage on the cost. This has nothing to do with patents. The success or failure of a torpedo boat or torpedo catcher turns on matters of proportion more than anything else. It is quite understood that everything about a torpedo boat is worked, so to speak, within an inch of its life. The smallest error in proportion may cause a breakdown, and this not only because the parts may be made too small, but because they may be made too large, and the last is just the error that a man lacking experience is most liable to make. We could cite more than one case of disaster brought about in this way. But it is quite out of the question to attempt to patent proportions; they none the less represent the maximum amount of technical value in such cases as we are considering, and the contractor has to pay for it to M. Normand, for example. Why does not our own Admiralty adopt a similar system, which would serve to secure to the country what is needed and would be fair to all concerned.

Nothing can be more shortsighted than the policy which we are criticising. What is true of Messrs. Yarrow's drawings is to a less extent true of the drawings of other firms. If the special designs of all the leading firms in any branch of engineering are to be sent to other houses, the result will be that the leading firms in each department will lose interest in carrying out Admiralty orders. Thus, if the Admiralty take the drawings of gun gear of all kinds constructed by Sir W. Armstrong and Co., and send them about the country, we have no doubt that firms will be found quite ready to work to these drawings although no member of the firm perhaps ever saw a big gun fired in his life. Can it be doubted that a pennywise policy of this kind must end in disaster?

It must not be supposed that in writing as we do we wish to hold up to reprobation any individual or set of individuals. We feel, indeed, quite certain that no one at the Admiralty, from the First Lord down, would countenance an act of injustice for a moment. Those concerned fail to see what they have done in its true light. The fault is the fault, not of individuals, but of a system, and of the way in which the system is carried out. The Admiralty should remember that they are not dealing in this case with foreign engineers, but with Englishmen. Any Government worth the name will regard those whom the nation employs, and who are paid out of the national purse, with friendly feelings. The Admiralty, however, appears to regard the engineers and shipbuilders of this country as enemies rather than friends. Throughout the length and breadth of the country we hear complaints, now of one thing, now of another. The relations of engineers and the Admiralty have long been strained. Let us hope that the episode which culminated on Tuesday night will bring about more satisfactory relations between those who ought to work together in very great harmony and concord.

## LORD SALISBURY'S ADDRESS.

Lord Salisbury's address as President of the British Association is the embodiment of the views of large numbers of earnest thinkers. It is a timely protest against the dogmatism and tyranny of science. It is often said that science is not dogmatic, that it is opposed to tyranny, and that the apparent exceptions, the existence of which are admitted, are to be traced not to science but to the idiosyncracies and prejudices of men. We refuse to accept this explanation. Modern science has no existence apart from the men who teach it. Knowledge has been specialised to the last degree, and it may be safely said that to go beyond the utterances of certain individuals is impossible. It is true that an interchange of knowledge and of ideas takes place; but, on the other hand, we have distinct schools or groups who regard themselves as the depositories of all existing information on particular subjects, and who maintain not unnaturally that their verdict on such subjects is final. In matters religious there is but one Pope. In matters scientific there are a hundred, each claiming in his own way to be infallible. Each always admits that he is open to conviction; but his attitude is that of the judge who, refusing to hear evidence for the defence in a certain case, asserted that it would be waste of time to call witnesses, because his mind was already made up. "But," said counsel, "surely, my Lord, you are open to conviction!" "Certainly," replied the judge; "but I should like to see the man who could convince me!" The general public may be divided into three classes: Those, by far the most numerous, who accept without question any statement made in the name of science, and go on their way without further regard for it; secondly, those who weigh what they are told, accept it with enthusiasm, are full of faith, and ready to go to the stake for the cause; and lastly, those who maintain that the man of science knows very little indeed concerning the tremendous problems which present themselves on every side to the thinker, and flatly refuse to accept any scientific dogma as true only because it is advanced by a man enjoying a fine reputation. This latter class may be said to be made up of intelligent heretics, and they are mostly regarded with despair and contempt by the man of science.

Lord Salisbury has played the part of the intelligent heretic to good purpose at Oxford. His weighty utterances will leave their mark. No one is better fitted to express an opinion than is Lord Salisbury. He is very far indeed from being ignorant of science. He is a competent electrician, for example. Few men living have had a wider experience of the operation of the human mind; its self-deceptions, its vanities, its mode of working. Few men have had greater opportunities for estimating the value of evidence—evidence, not of the minute and detailed kind to be found in our law courts, but of that larger and wider kind selected from the contentions of nations, the world of diplomacy, and the strife of party. His knowledge of science while sufficient to prevent him from falling into error has left him free from the prejudices of the scientific schoolman. When a biologist has spent his best years in proving to his own satisfaction that he has descended from a jelly fish, it is unlikely that he can properly appreciate arguments showing that he is wrong. But Lord Salisbury is in a different position; he can estimate at their proper value the arguments for and against. The result of his labours is that he takes the book of science and he writes on almost every page the words, "Not proven," and there is none that can answer him, or demonstrate that he is mistaken. Of the foundations of Nature we know nothing, nor are we likely to know anything, and so we find Lord Salisbury, like Clerk-Maxwell and Lord Kelvin, referring not the origin of things alone but their conduct to a Great First Cause, and telling us, "That all living things depend on one everlasting Creator and Ruler."

But dogmatic as science is, we find that its dogmatism is not general but particular. It is not the dogmatism of one Catholic creed, but that of a hundred creeds. It is next to impossible to find union, harmony, or charity in the ranks of science. It has been happily remarked that the brain does not discriminate what it is thinking about, and the expenditure of mental energy is just as great in settling what we shall have for dinner as in solving a mathematical problem; in composing a speech to be delivered before the vestry of Little Peddlington, as in preparing one to be delivered in the House of Commons on the Navy Estimates, or the relations of this country with the Boers. In the same way the clash of scientific opinions; the display of warlike energy; the outpouring of the spirit of contention, is in scientific matters in no way different from all that obtains in affairs political or national. Lord Salisbury told his hearers that the views of the biologist were quite incompatible with those of the geologist; but we know very well that neither will give way. The outsider, judging between them, will arrive at the conclusion that neither possesses any sufficient evidence to enable him to arrive at the most remote approach to certainty. Nor is this incompatibility of theory and statement confined to class against class. The war is civil. Contention pervades every camp. Take, for example, the discussion which has recently gone on in our pages. It is very probable that Dr. Lodge is as eminent an authority on thermodynamics as it is possible to get. He is a professor, and a teacher of large numbers of students. To him comes Mr. Peter Alexander, who, following the example set by Mr. Branson in our railway stations, does not call a spade an agricultural implement, and very plainly asserts that Dr. Lodge does not know what he is writing about. But Mr. Peter Alexander is a professor just like Dr. Lodge, and he, too, teaches numbers of students. Our text books dogmatise and repeat each other. The only point on which men like Dr. Lodge and Professor Alexander agree is in denouncing the text books. Is it wonderful that the school which Lord Salisbury represents, a school of able, thoughtful, mostly silent men, regard the disputants with amusement, and refuse to accept their statements as absolutely true? In a word, Lord Salisbury is a scientific agnostic, holding that while our knowledge of nature and nature's operations has progressed rapidly, and may yet progress still more rapidly, little is known with such certainty that it is safe to assert that knowledge is final. Until the other day, the man who would assert that anything remained to be discussed about the composition of the atmosphere would be regarded as grossly ignorant of the results of chemical research. Lord Rayleigh has just fluttered the scientific world by announcing the discovery of a new gas. For years the world has been content to accept as a proved fact that 460 Fah. is absolute zero. Mr. Donaldson says it is not demonstrable that this is true, and no one has attempted with any approach to success to refute him. Indeed, we understand Professor Alexander to admit the general validity of his arguments. The theory of the action of steam in an engine is quite unsettled, notwithstanding the most dogmatic assertions on the subject. In great things and in small, nothing is more obvious than the absolute ignorance of mankind. It behoves the scientific man to be the most modest of animals. Lord Salisbury has put this truth into admirable phrase and sentence. We can scarcely doubt that he will do good. We have heard it seriously urged that such an address must do harm, in that it will unsettle young men's minds, and lead them to doubt the infallibility of their teachers. By all means let it be so. Empirical science is being ladled into the younger generation as Mrs. Squeers supplied brimstone-and-treacle to the wretched population of Dotheboys Hall. The modern teacher has yet to learn how to say "I believe," instead of "I know." Lord Salisbury's address may smooth the way for the change of words.

◆

### SHEFFIELD AND THE AMERICAN TARIFF BILL.

Apart from the textile towns, no place in England is more closely affected by the United States tariff than the capital of the cutlery trades. At one time America was the key to the whole Sheffield business. That situation no longer exists, and it is still the case that a good business is done with American markets, and much more would be done if the duties were not practically prohibitive. The great expectations formed when the Wilson Tariff Bill was originally submitted have of late been greatly modified, and the strife of parties has recently made England despair of a settlement. Now, however, there seems a clear course to an arrangement. The House of Representatives, evidently believing that the Senate wished to postpone indefinitely the whole tariff question, have adoped the prudent course of taking half a loaf rather than have no bread. In other words, they have abandoned their own Bill and accepted that of the Senate. At Sheffield the reduction of the duties on steel is expected to bring about a substantial accession of business. A large quantity of the steel used by the German, French, Spanish, Swedish, and Russian manufacturers is made in Sheffield, and if the continental makers beat the home manufacturers, further trade will be done from Sheffield with the markets named. In cutlery, the reduction in the new tariff represents a relief of about 25 per cent. as compared with the McKinley Act. In cutlery, as in steel, the very best productions continue to be largely Sheffield monopolies. Lower grades of steel and cheaper qualities of knives can be produced on the Continent and in the States; but the Americans have made singularly little progress in the direction of superior cutlery. This is largely due to the habits the Americans have of "riving" their meat asunder, instead of cutting it cleanly with a sharp knife. In the large hotels and restaurants the men who carve the meat require a tool; hence the great business done in carvers with the States. The number of carvers sent to the Americans is out of all proportion to the table cutlery exported to that market. English carvers are still the rule, and no good hotel hand will have anything else. The intention of tariff reformers in the States is to keep in the country the trade the country can do. Hence the relief in the secondary grades of goods. The future trade of Sheffield with America will mainly be in the best steels, the finest classes of table cutlery, carving knives, pen and pocket knives, hollow-ground razors, and what are known as "case goods"—presentation cabinets of highly-finished articles.

### JAPAN AS A MACHINERY MARKET.

Machinery engineers in this country engaged in the manufacture of cotton spinning plant have of late been doing a large trade with Japan, China, and Russia, and there are evidences that this trade may continue and extend. But it appears that engineers should be cautious with regard to machinery sent to Japan. English machinists must, it is stated, not lose sight of the fact that foreign patents are not protected in Japan. When one machine, patented elsewhere, is obtained, and is fairly easy to imitate, the imitation is at once begun by native labour. A machine capable of doing the same work is then turned out at possibly half the price of the imported plant. In short, it is said that English makers should be very careful about supplying information regarding machinery, "as they cannot tell to what use such information may be applied." This warning has come none too soon. The Japanese have always been noted for their remarkable ingenuity in mechanical matters, and although deficient in the gift of invention, they can alter or copy an original with surprising ability. The enterprise which they are showing in the cotton spinning industry is noteworthy. At present Japan is within measurable distance of the active employment of 700,000 spindles, and it is understood to be the intention of the capitalists promoting this enterprise to increase the spindles shortly to 1,000,000. While, therefore, there is every reason for anticipating a continued large demand of spinning machinery, Lancashire engineers should not give themselves away more than they can help.

### HARVEY ARMOUR TRIALS.

We have received a letter from Mr. Fox, the representative of the Harvey Company in England, pointing out that the two reports of plates tried, dealt with in The Engineer of August 10th, referred to two different plates, as we see now in reading Mr. Fox's letter again. It is satisfactory from every point of view that this should be the explanation of the apparent discrepancies in the accounts. As the matter now stands, a thick Carnegie-Harveyed plate behaved badly, and a thick Bethlehem-Harvey plate behaved very well. That one plate should be a failure is nothing very extraordinary, but no doubt was a serious disappointment. The report of the first trial was reckless in its figures for energy, as we pointed out, but surely the plate was intended as a test plate as reported. Mr. Fox tells us that the plate was not a fair representative plate, and had structural defects. The question then arises whether this was known before the trial, or only then discovered, because if the latter, as we presume, it argues an element of uncertainty which, as we have had occasion to point out, has before now been found in treated plates. This may be got over by experience, and we are right, we believe, in saying that Bethlehem has had more experience than Messrs. Carnegie in treated plates. Certainly if one plate argues possible disappointment, the other argues possible success in really thick Harveyed plates.

## LITERATURE.

*Mining: An Elementary Treatise on the getting of Minerals*, By Arnold Lupton. 8vo., 519 pp. London: Longmans. Green, and Co. 1893.

This treatise, which in the words of the preface "is prepared exclusively for the use of those who wish to teach beginners, or as a handy reference book for busy men whose excess of knowledge and experience causes them sometimes to forget their early lessons," is the work of a busy man who, in addition to an active professional practice, finds time to perform the duties of the two Professorships of Mining at Leeds and Derby, besides acting as Examiner to the City and Guilds Institute of London. The order of arrangement followed in the text, which is generally similar to that usually adopted in elementary books, commences with an introductory chapter on general geology, containing much that is not to be commended, and is followed in regular order by others on exploration, boring, mining, sinking, winding, ventilation, pumping, and all the numerous operations required to bring the produce of the mine into a marketable form. The author's long practical experience has in most of these sections been largely utilised, and the descriptions of actual mining works are very fully given. Among these, one of the most interesting notices is that of the difficult sinking through river alluvium and boulder clay of the large shaft at the Bettisfield Colliery near Bagilt, in North Wales, which was carried out by the author under the direction of the late Mr. J. T. Woodhouse, and is the only instance in which compressed air has been applied to pit sinking in this country. The development and utilisation of power in winding, air-compressing, and other engines used in mines, is treated more in detail than is generally the case in elementary books, the subject being further elucidated by the discussion of diagrams taken from several large winding engines at work in the North of England and Midland coalfields. There is also a useful appendix, giving a series of examples of the methods of working out the leading dimensions of colliery engines as a preliminary to the preparation of detailed designs, the latter subject, of course, being beyond the province of the book. The text is profusely illustrated by sketches, many of which are apparently reduced from lecture diagrams, and are simple and effective, except where the reduction has been pushed almost to the point of invisibility, as, for instance, the scroll drum winding engine, Fig. 513, which covers a space scarcely larger than a postage stamp. Taken as a whole, the chapters devoted to colliery engineering—and these form the principal part of the book—are excellent, but unfortunately as much cannot be said of the author's treatment of metalliferous mining. He has, however, introduced a decided novelty in this part of the subject—on page 19—namely, a list of minerals known to miners, which are said to be fifty-eight in number—rather a startling reduction upon the 600 or 800 species known to mineralogists. As, however, this limited and reduced mineralogy is obtained by allowing one mineral—and one only—as an ore to each metal, the result can scarcely be of much value either to teachers, beginners, or busy men. In the chapter on mining tools, it is said that "the pick is commonly made of cast steel, and sometimes of shear steel. When made of shear steel, the body of the pick is made of iron, and the steel welded on; when made of cast steel, the whole is cast in one piece." This would seem to imply that mining picks are cast to pattern in steel. Surely this is not a general practice? We have also been puzzled by a statement on page 448, that Jordan's water-pressure engines at Clausthal were quite new when seen by the writer in 1883. Judging from the illustration—given in Fig. 568—these appear to be the same engines that were set to work in December, 1876, and would have been between six and seven years old at the date mentioned by the author. Were they actually new engines that he saw? Because if so, those put down at first must have worn out very rapidly.

## *BOOKS RECEIVED.*

*Three Periods of English Architecture.* By Thomas Harris, F.R.I.B.A., F. San. I. London: B. T. Batsford. 1894.

*Society of Engineers' Transactions for* 1893 *and General Index*, 1860 *to* 1893. Edited by G. A. Pryce Cuxson, Secretary. London: E. and F. N. Spon. 1894.

*Dynamo Attendants and their Dynamos.* A practical book for practical men. By Alfred H. Gibbings, A.I E.E. London: Sidney Rentell, 29, Ludgate-hill.

*Minutes of Proceedings of the Institution of Civil Engineers.* Vol. cxvi. Edited by James Forrest, Assoc. Inst. C.E., Secretary. London: The Institution. 1894.

*Rylands' Hardware (including Jewellery, Pottery, and Saddlery.)* A complete directory of Midland manufacturers, 1894. Birmingham: Published by the proprietors of the *Iron Trade Circular* (Rylands') at their offices, 46, Union-passage.

## THE L. AND N.W. RAILWAY COMPANY'S S.S. BANSHEE.

The London and North-Western Railway Company express paddle steamer Banshee has recently been fitted by Messrs. Laird Brothers with new machinery on the tri-compound system, after the pattern of that made by the same firm for her sister ships Lily and Violet, about three years ago, and fully illustrated in our issues for April 17th, May 1st, and August 7th, 1891. The official trials were made last week between Dublin and Holyhead.

On the 30th July she left Holyhead for Dublin, and made the passage from the Breakwater to Poolbeg Light in 2 hours 46½ min., the fastest on record; to the Kish Light her speed was over 21 knots.

The return run was made on Wednesday, the 1st August, in 3 hours 3½ min. During the first half a speed well over 21 knots was recorded, but the latter part was spoilt by a slight derangement of condenser tubes, coupled with adverse ebb tide and considerable roll of sea.

On Tuesday, the 7th inst., she completed her trials by a run from Holyhead round the Kish Light and back to Holyhead—a distance of 96 knots—the machinery working admirably, and the speed attained being fully half a knot in excess of that promised by the contractors. The run to the Kish Light occupied 2 hours 21 min., the engines making thirty-six revolutions with 4750-horse power. The return run against the tide with a rough beam sea and southerly breeze occupied exactly the same time, with thirty-eight revolutions and 5150 indicated horse-power, the speed for the whole time being 20·42 knots. There is remarkably little vibration, and the vessel is extremely handy.

The hull has been thoroughly overhauled, the cabins redecorated, and new furniture, and a complete installation of electric lighting provided. The engines consist of a set of triple-expansion steeple engines. The cylinders are bolted without the intervention of any bed-plate to the engine-room keelsons by ordinary holding-down bolts, and secured to the entablature above by wrought iron columns. The cylinders are placed in line athwartships, the low-pressure being in the middle, the high-pressure on the port side, and the medium-pressure on the starboard side. The pistons and piston-rods, the bowstring crosshead pieces, and the connecting-rods, as well as other parts, are of steel. Owing to the small athwartship space in which it was necessary to place the three cranks, the valve chests are placed on the aft side, and excentric motion dispensed with. The type of valve gear adopted is Joy's, which is well known as possessing the good point of occupying little room. Piston valves are used for the high-pressure and medium-pressure engines, and a balanced D-slide for the low-pressure engine. The reversing gear is attached to the upper framing which supports the guides, and is worked by a steam and hydraulic engine. The crank pins, crank shafting, and paddle shafting are of hollow steel. All the bearings have a very large wearing surface. The condenser is placed in the fore part of the engine-room. The circulating water is supplied to it by a 16½in. centrifugal pump, driven by a compound engine. The air pumps are of special design. There is a vertical triple-expansion engine placed immediately over the three air pump cylinders, each steam cylinder and pump cylinder being in line, the crank shaft being placed between. The main feed pump is separate, and there are also auxiliary steam feed pumps, bilge, and fire pumps.

Steam is generated in six boilers of the locomotive marine type, at a pressure of 155 lb. on the square inch. They are placed in two groups of three each, in two closed stokeholds. Air is supplied to the furnaces by two large fans situated on the upper deck, driven by two sets of compound vertical engines. The air pressure is three-quarters of an inch of water. A winch boiler is fitted in the after stokehold for use in port. The paddle-wheels are fitted with curved steel floats of special design.

# SOME REMINISCENCES OF STEAM LOCOMOTION ON COMMON ROADS.*

By Sir FREDERICK BRAMWELL, Bart., F.R.S., M. Inst. C.E.

IT has occurred to me that this paper may have some interest for Section G on two grounds:—(1) That it deals with a branch of mechanical engineering of which the present generation knows practically but little; and (2) that it involves, very largely, the subject of water-tube boilers or their equivalents.

I do not propose, in this paper, to give the whole history of steam locomotion on common roads, beginning with Cugnot's carriage—which it is reported really did move in Paris at some three miles an hour, as long as the steam kept up—as far back as 1769, nor to mention the propositions of the ingenious American, Oliver Evans, in 1772, whose plans, so far as regards common road carriages, it appears were never carried out; nor do I propose, in this paper, to occupy any time about steam traction engines or road rollers, nor about steam motors on tramways; but I mean to confine myself to a description of some of the steam coaches, which carried passengers generally on the same carriage as that on which the engine and boilers were mounted—a construction which, so far as I am about to deal with the subject, it will be found was departed from only in the case of Sir Charles Dance's engine, hereinafter mentioned. As indicated by the title of my paper, I intend to confine myself to *some* reminiscences on this subject, embraced, so far as my own knowledge goes, between, say, six or seven years in the thirties or forties of this century.

I think I am right in saying that by about 1825 our turnpike roads, and the stage coaches which ran upon them, had attained to the highest degree of excellence. At this time passenger railways were practically "in the air," omnibuses were running in London, and cabs were superseding the old hackney coaches; and there was a general feeling that on our magnificent turnpike roads increase of speed and economy could be attained by the employment of the steam engine, and it was also felt that such a mode of propulsion would compete successfully with the omnibuses. The natural result was that very many men, more or less ingenious, and more or less practical, devoted their attention to the subject of steam locomotion on common roads. I propose to describe, briefly, some few among the whole number of those inventions which really resulted in carriages that did practical running on common roads. Certainly the most enduring and successful of these men was Walter Hancock. He took great notice of me, then an apprentice, and, after his day's run in London, frequently took me down on the coach to his factory at Stratford. I became very much interested in this subject, and took occasion to see all that was to be seen, and to hear all that there was to be heard. Another coach that did good service was that of Summers and Ogle. Summers was son-in-law to the engineer Hague, to whom I was apprenticed. I was thus, as it were, in a steam-locomotion-on-common-roads-atmosphere.

In 1830, as you all know, the Manchester and Liverpool Railway, which I think I may fairly call the first real passenger railway, was put to work. Nevertheless, in 1831, a Parliamentary Committee of the House of Commons was constituted, which Committee reported in 1833, and I think it only fair to the enterprise of steam carriages on common roads, to give the summary of their report. It is as follows:—"(1) That carriages can be propelled by steam on common roads at an average rate of ten miles per hour. (2) That at this rate they have conveyed upwards of fourteen passengers. (3) That their weight, including engine, fuel, water and attendants, may be under three tons. (4) That they can ascend and descend hills of considerable inclination with facility and safety. (5) That they are perfectly safe for passengers. (6) That they are not—or need not be if properly constructed—nuisances to the public. (7) That they will become a speedier and cheaper mode of conveyance than carriages drawn by horses. (8) That, as they admit of greater breadth of tire than other carriages, and as the roads are not acted on so injuriously as by the feet of horses in common draught, such carriages will cause less wear of roads than coaches drawn by horses. (9) That rates of toll have been imposed on steam carriages which would prohibit their being used on several lines of road, were such charges permitted to remain unaltered." You will see that by Section 9, they refer to the excessive tolls, and state that such tolls would be prohibitory, if they were to remain unaltered. With respect to these tolls, the Committee give the following illustrations:—"On the Liverpool and Prescot-road, Mr. Gurney's carriage would be charged £2 8s., while a loaded stage coach would pay only 4s." "On the Bathgate-road, the same carriage would be charged £1 7s. 1d., while a coach drawn by four horses would pay 5s." "On the Ashburnham and Totness-road, Mr. Gurney would have to pay £2, while a coach drawn by four horses would be charged only 3s."

But not only did the opponents of steam carriages on common roads oppose them by obtaining heavy tolls to be laid on, but they used actual physical obstruction, as appears by the following:—In a letter of the 3rd February, 1832, from Sir Charles Dance to Mr. Gurney, it is stated that on the 22nd June, 1831, "It was reported to me by my engineer—Mr. Stone—that large heaps of stones were laid across the road about four miles from Gloucester, 18in. deep, which the engine had passed over twice—in going to and returning from Cheltenham—with considerable difficulty, and that it was so unusual a mode of repairing a road—which was in excellent order and required no repairs—that it must be a serious obstruction to all descriptions of carriages." Mr. Stone's letter of the 22nd June, 1831, accompanies Sir Charles Dance's letter. It is as follows:—"Yesterday morning we found the road filled up with loose stones for a considerable way near the four-mile stone. The carriage with difficulty went through them, and also returned through them again, without any mischief, but the third time the strain broke the axle between the throws. The horse coaches have been stopped in the stones. The clerk at the Branch Bank of England says that he came across by the mail this morning, and that it was also stopped. Mr. Todd, of Cheltenham, says he was obliged to get down from the coach he came to town by, and that the horses could not get it through. The Champion, from London, a fine four-horsed coach, was brought up, and, in whipping to get through, broke the harness to pieces. Wagons are obliged to get extra horses, in fact the proceedings are most unaccountable. It is some relief, however, to know that the steamer has gone through, where the horses have been brought up, and I hope soon to get the axle mended."

But I do not think that either excessive tolls or road obstructions were the real cause of the cessation of the steam carriage enterprise upon common roads. Year by year railways were increasing, and the public lost interest in the common road steam carriage, which was merely to develope a speed of some fifteen miles an hour, which required a large expenditure of power for the weight moved; and they turned, and wisely turned, towards the iron way. Among the six or seven names with which I am most familiar, it is difficult to assign any definite order of sequence of invention, inasmuch as, in some cases, the same inventor took out patents at varying dates. Hancock had a patent in 1827; so had Gurney; Summers and Ogle, in 1830; Church, in 1832; Maceroni, 1833; Dance, 1833; and Hancock, another patent as late as 1839. Hancock, and most of those who worked on the subject, dealt very wisely in one most important respect, with their carriages to be used on common roads; that is to say, the vehicles themselves were very commonly like a large stage coach, or—as I shall have to say with respect to Hancock—were of the omnibus form, or deviated from this, by the adoption of the char-à-banc construction. With the exception of the driving wheels, there was no moving part of the machinery visible. There was no noise from the exhaust—in the best of them—nor any visible indication of fire or steam, that is to say, neither smoke, nor a white cloud. Their appearance, therefore, was not such as to be, of necessity, alarming to horses. No doubt it was true that during, say, the first week of the running of a steamer upon a regular journey, such as the Bank to Paddington, horses would pay some attention to it, but at the end of a week the horses habitually using the road were absolutely indifferent, and, in fact, horses generally were very little disquieted. But for years after Hancock steam locomotion on common roads remained in abeyance, and when it was taken up again, it was with the totally different object of traction engines, travelling ploughing engines, and road rollers. These were carried out by some of the best of our mechanical engineers, and, as machines, were excellent; but with respect to the horse difficulty, were about as bad as they well could be. All the moving machinery was visible; there was the "barking noise" due to the steam blast; they occasionally emitted fire; and their general forms must have been an abhorrence to any horse possessed of the slightest particle of good taste. The result, as we know, has been legislation, confining the use of these vehicles to night, or, if worked in the day, to be preceded by a man with a red flag and the various paraphernalia.

I will now give a few particulars of the steam carriages to which I have already alluded, and I will commence with that of Hancock. In his case I propose to give a longitudinal section of one of his char-à-banc coaches, such as the "Infant," one of the earliest, or the "Automaton," the latest of those he built; but, generally, I shall confine myself to illustrations of the boilers, as probably these are more interesting in the present day than are the details of carriage and engine construction. Fig. 1 is a longitudinal sectional elevation of one of Hancock's carriages of the char-à-banc construction, with a sheltering roof. I may as well here give a list of Hancock's coaches:—The "Infant," of the form shown on the diagram. The "Era," which became converted into the "Erin" when it went to Ireland; this had an ordinary stage-coach body. The "Enterprise;" this had an omnibus body. The "Autopsy;" I cannot remember what was the nature of the body of this carriage, although I remember the name. The last carriage of all, the "Automaton," was a covered char-à-banc construction, as shown on the diagram. In all cases the passengers and the engine and boiler were carried on one and the same structure; except when, to show the power of the engine, an ordinary omnibus body was towed behind the steam carriage.

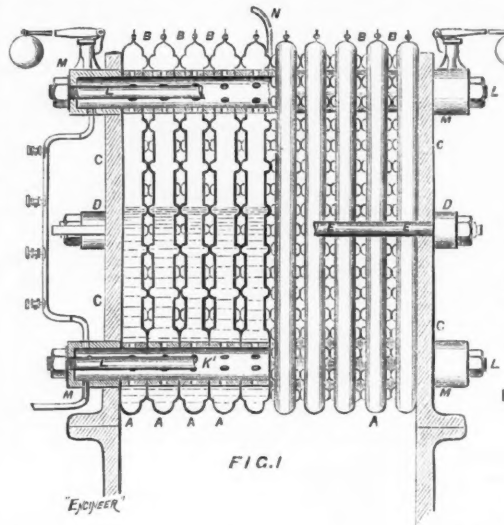

FIG.1

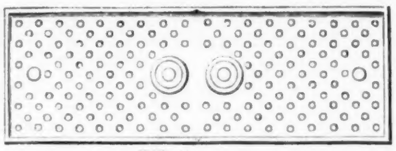

FIG.4

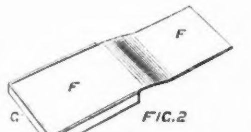

FIG.2

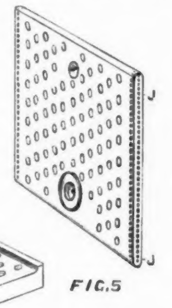

FIG.5

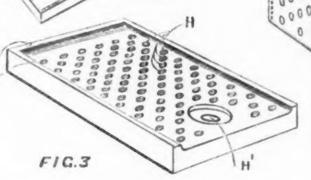

FIG.3

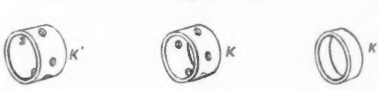

FIG.6

Whatever may have been the nature of Hancock's earlier experiments, he settled down into a construction of boiler consisting of a number of flat chambers placed side by side, with spaces for the ascent of the products of combustion in between the chambers containing the water. Time will not admit of entering into the details of the steps by which the construction of boiler eventually employed in his steam coaches was reached, and I will content myself, therefore, by dealing with the perfected boiler as I knew it. The boiler was an equivalent for a water-tube boiler, in that, as in water-tube boilers, the fire was outside the water, and not inside. This boiler combined lightness, strength, and large heating surface. Fig. 1 is an end elevation, one-half in section. It shows a number of narrow chambers, *a*—10 are drawn—placed side by side like books on a shelf, with this important difference, however, that between each chamber *a* there was left a space *b*, through which spaces the products of combustion passed. At the outsides of the outside chambers—Nos. 1 and 10—were very stout wrought iron plates *c*. Beyond these were girders *d*, *d*, &c., longer than the width of the plates, so that the ends of the girders projected clear beyond the width of the chambers. Through holes in the ends passed tie-rods *e*, *e*, &c., across the whole length of the boiler, by which rods the various chambers of the boiler were held together. But it will at once be seen that, as there were spaces *b* between the chambers *a*, these tie-rods *d* could not be effectively tightened up, because there was an absence of any proper abutment for them to pull against. This abutment was provided for in a manner which I will mention in the description I am about to give of the mode of manufacturing the chambers.

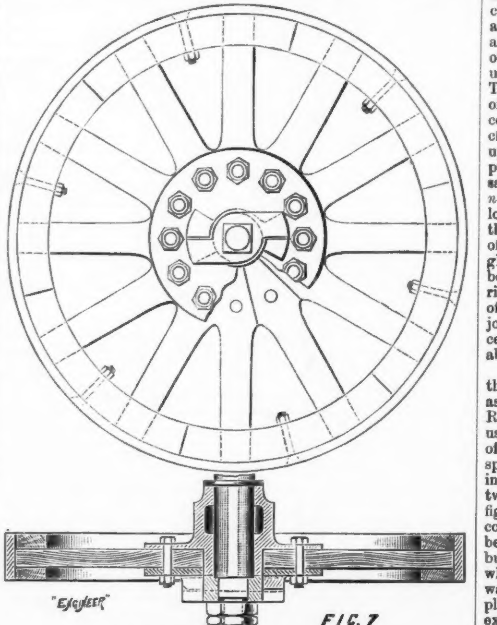

FIG. 7

Fig. 2 shows a flat plate *f* of copper or of soft iron, laid upon a cast iron slab *g*—which slab is shown separately in Fig. 3—provided with indentations having the shape of segments of spheres—practically hemispherical—*h*, *h*, *h*, &c., and a larger flat indentation *h*. The slab *g* was also provided, around three sides of its margin, with a raised rim *i*. About one-half of the plate *f* is laid over *g*, and by means of hammering, is caused to pass into and to take the forms of the depressions *h*, *h*, *h*, in the slab *g*. The other half—about—of the plate *f* is treated in the same manner, giving the result shown in Fig. 4. The plate *f* is now bent up into the form shown in the general elevation. It will be seen that there has been made out of the metallic plate *f* a flat chamber, in the form and of the construction of a "biscuit bag;" as in this bag there is no joint at the bottom, so that there are no rivets exposed to the direct action of the fire, but the riveting is confined to the two sides and to the top. It may be well to say here that there was an alternative mode of construction, which consisted in the making of a channel iron *j*, which was put in between the sides of the flat plate *f*, so that those sides needed not to be "set in," as was previously mentioned. This gave a double line of rivets. The construction is shown isometrically in Fig. 5.

Passing away from this alternative mode of joint-making and reverting to the chamber, I will call attention to the circular holes—according to my recollection, of about 3in. or 4in. in diameter—which were made through the walls of the chamber at the upper and lower parts, in the large flat circular projections provided for this purpose at the lower part, and in the plain wall of the chamber at the upper part. Before the chambers were riveted up, there was put into each of them two gun-metal rings *k*, *k*—see Fig. 6—the top rings *k* being narrower than the bottom rings, *k*. The internal holes in these rings were of the same diameter as the holes in the sides of the chambers. The radial holes were to make connection between the body of the chamber and the internal holes in the ring. When the chambers were put together, the rings were brought to be concentric with the holes in their sides, and intermediate rings. *k* 2 without radial holes, being put at the upper parts between the chambers, there was passed through the whole number of chambers at top and bottom strong tie-bolts *l*, leaving, however, an annular space between the exterior of the tie-bolts and the interior of the rings. On the outside chambers hollow sockets were placed, upon the close ends of which bore the nuts of the tie-bolts *l*. These sockets are indicated by the letter *m* in the general view of the boiler A. By this simple arrangement there was formed a complete connection for the water at the lower part of all the chambers, and another similar connection for the steam at the upper part of the chambers. Into one of the lower sockets was pumped the feed-water, and on the upper sockets were placed the safety valves. The steam to the engine was taken off by the pipe *n* from the central intermediate ring *k* 2. The upper and lower sockets were also connected by a vertical pipe, external to the fire-casing, in which were placed, at frequent intervals, a series of—not gauge *cocks*, but—gauge *valves*, to serve the purpose of a glass water-gauge. It should have been stated that the joints between the various chambers were made by a simple copper wire ring, somewhat flattened out by the pressure produced by the nuts of the tie-bolts. For years past such or similar modes of making joints tight have been well known, but Hancock was the first, or certainly among the first, to dispense with red lead and other abominations, and to make metal-to-metal tight joints.

In connection with Hancock's boiler, it may be mentioned that the same principle of using a series of flat chambers, so disposed as to cause them to support each other, was adopted by a Mr. Redmund, a malleable iron manufacturer in the City-road, who used corrugated plates for the sides of his chambers—the summits of the corrugations impinging the one upon the other—in the flue space. He made his two vertical seams of each chamber by riveting the plates together, and formed the top and bottom joints by two malleable iron castings, having the requisite corrugated configuration at their edges, which castings were inserted between the corrugated plates, the rivets going through all. I do not remember how he made his steam and water connections. I am not sure, but I believe that this boiler was put into a steam carriage, which, however, was a failure. Hancock's collection of chambers was placed a short distance above the fire, or in the last patent was placed not directly over the fire, but at the side. There was an external casing which contained the boiler, the fire chamber, and the ash pan. This pan was closed and the draught was excited by a fan driven off the main engine. The waste steam was blown into the ashpit and passed up through the fire, with the result that, except upon a very damp morning, at first starting there was not, as I have already said, any visibility of the waste steam, neither was there any sound. The safety valve, also, when it blew off, delivered the escaping steam into a silencing box. Fig. A shows that the engines were of the inverted vertical type, working on to a crank shaft, carrying a pitched pulley for a chain. This pulley could be uncoupled from the shaft by a clutch, and then the engines could be worked to drive the fan to get up steam, or to feed the boiler. I need hardly say this was long before the days of injectors, and was also long before any common use of donkey engines. On the axle of the hind wheels was a corresponding pitched pulley, either of equal diameter with that on the crank shaft or, I am inclined to think, of somewhat greater diameter. The wheels were of wood, having very strong spokes, enclosed in a cast iron nave with covering plate. They were loose upon the ends of their shaft, and had on the outsides of the nave two driving projections—Fig. 7. On the ends of the shaft were two drivers, which could be drawn out of gear with the wheels by screws. In ordinary running both drivers were in gear, but it will be seen there was left a very large amount, probably 100 degrees or more, of that which may be called "back-lash." Supposing that, in steering through the streets, it became necessary to make a slight curve, the result was that the wheel on the inner side of the curve did the driving, while the wheel on the outer side over-ran the driver. It thus became possible to follow a sinuous track with great ease, so long as the curves were inconsiderable in length. When it became necessary to make a very sharp curve, as, for example, to turn the coach completely round in a very small yard, in Wenlock-place, City-road, provided with only a single entrance, the clutch of the inner wheel of the intended circle was drawn completely out of gear, leaving the turning to be done by the outer wheel. In this way, the coach was got round practically in its own length, the fore carriage being competent to lock to such an extent as to put the centre of the circle but a small distance away from the inner wheel. This elaborate preparation to accommodate the driving wheels to the conditions needed when making a curved track, would, in these days, be, of course, wholly unnecessary, on account of the employment of the "Jack-in-the-box" arrangement, to attain the desired end, and to do so in a much better way. "Jack-in-the-box" has long been employed in traction engines, and, indeed, in the Exhibition of 1862, a passenger carriage, built by Messrs. Garrett and Marshall, of Leeds, for Mr. George Salt, of Saltaire, was fitted with this apparatus.

---

* Paper read before Section G of the British Association at Oxford, 9th August, 1894.

FIG. 8

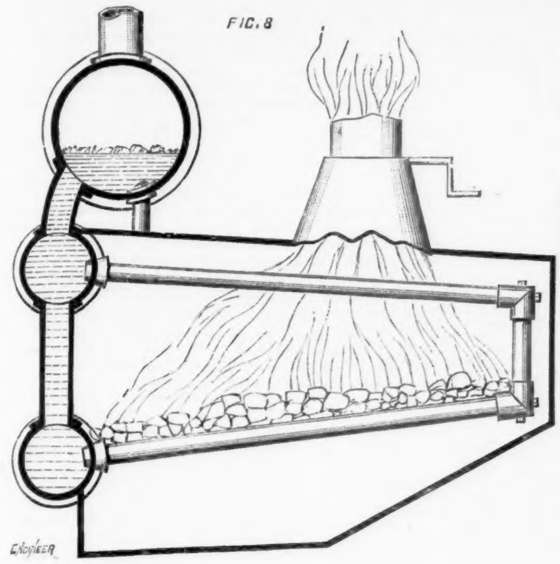

FIG. 10.

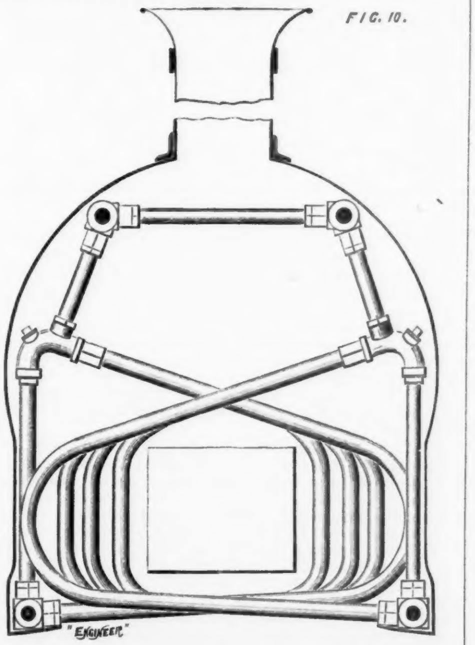

In the latest of Hancock's coaches, the "Automaton," provision was made for partially condensing the exhaust steam by passing it through condensers of somewhat the same construction as that of the boilers, and placed in the water tanks which were under the floor of the char-à-banc. I am under the impression, however, that these were never a success. In fact, Hancock thought of every detail tending to the efficient working of his coaches. For example, he met a considerable difficulty that arose from the clinkering of the fire bars, by two methods. The first was to put the bars into a sliding frame, so arranged that while the clean bars were at work supporting the fire, the dirty bars were altogether outside the fire casing, so that they could be cooled down, and then the clinker could be readily removed. When this had been accomplished, the outside set of bars were fit to be slidden under the fire, while the bars which had been in use were, in their turn, brought to the outside. An alternative plan was, to make the fire-bars circular, lying in supports, and having projecting ends, made to take a winch handle. In this way the bars could be turned in succession, breaking them away from the clinker, which was then readily removable. Another, and a great precaution to prevent "priming," since then, no doubt, very largely used, was, I believe, Hancock's idea, namely, the taking away the steam from the boiler through a very restricted orifice. My recollection is, but I do not speak with perfect certainty, that the pair of 10in. cylinders—or they might have been 12in.—in the "Automaton" were supplied by a $1\frac{1}{4}$in. steam pipe. This pipe had a coil bend in its passage from the boiler to the engine to admit of any variation, owing to the straining of the framing between the boiler and the engines, and thus to obviate the chance of fracture of the pipe.

In these days—as I have said—injectors were not, and considerable difficulty had from time to time been experienced by the sticking up of the valves of the feed pumps. To guard against this, Hancock used two suction valves in succession, and two delivery valves in succession. The steering was done by means of an ordinary fore-carriage fixed upon a central vertical pin, carrying a pitched chain wheel geared up to a wheel of the same kind, keyed on to a vertical steering spindle, on which was a hand wheel. It was found in the outset, especially when going over pavement, that the blows inflicted by the pavement on the fore-wheels were communicated to the arms of the steersman with a very distressing effect. This was entirely got over by the simple expedient of a foot-brake. These coaches worked for a period of over twelve years. They, or some of them, made long journeys with great success; but their most interesting use, as showing the ability of steam-driven coaches to cope with the needs of the traffic of a great city, of many road materials, and of gradients exceeding that of any hill on the road from London to Holyhead, was their lengthened employment for ordinary omnibus traffic between the Bank and Paddington, and, morning and evening, between the Bank and Stratford. The journeys were made regularly from Paddington to the Bank, backwards and forwards, involving, on the homeward journey, the ascent of Pentonville Hill. Not only did his various carriages surmount this ascent without difficulty, but on more than one occasion did they accomplish it even when towing an ordinary omnibus full of passengers behind them. The New-road, and Pentonville-road, were macadam; the City streets were then of granite pitching, and the Stratford-road was of gravel. Over the whole of these different formations the coaches worked perfectly. The weights of these coaches varied in working order from $3\frac{1}{2}$ tons to $4\frac{1}{2}$ tons.

FIG. 9

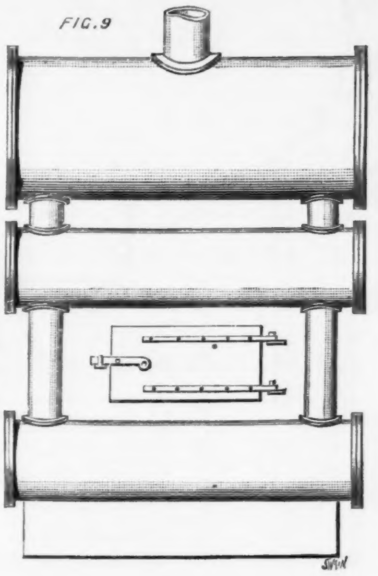

FIG. 12

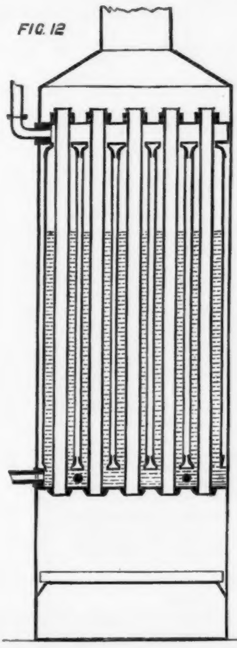
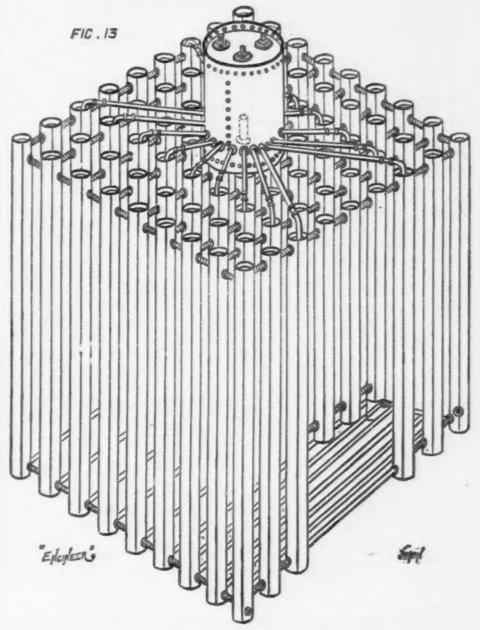


I am aware that I have spent much time over Hancock, more than I can afford to any other of the steam coaches, but I think Hancock is entitled to this extent of notice, because he persevered more than any other person who devoted himself to the subject, because I believe he understood its practical working better, and because he attained a far greater measure of success.

The next carriage with which I will deal is that of Goldsworthy Gurney. Fig. 8 is a longitudinal section of the boiler and of outside view. This, it will be seen, was essentially a water-tube boiler, and consisted of two main tubes—cast iron I believe they were—placed horizontally parallel the one above the other; from the lower end of these main tubes there issued a series of wrought iron tubes slanting upwards for some distance, and then bending, continuing on, over and to the top main tube. This carriage—or rather these carriages—made various experimental runs with more or less success, notably one from London to Bath, and worked for a considerable time between Cheltenham and Gloucester, but was eventually abandoned. I never saw it running, nor did I ever see it together as a whole; my personal knowledge was confined to the boiler, and was of the character of that of the converted cannibal who, being asked what he thought of the late bishop, said he knew he was a very nice man for he had eaten a bit of him. The very first day of my apprenticeship was occupied in holding the chisel rod for a labourer who was cutting up the boiler into scrap. The boiler drawing speaks for itself.

The next carriage I will mention was that of Sir Charles Dance. This was a steam traction engine, and had no seats for passengers, but towed an omnibus behind it. The engine was built by Messrs. Maudslay and Field. Fig. 10 gives a transverse section of the boiler, and Fig. 11 an enlarged detail. This boiler, it will be observed, is a strictly water-tube boiler, and, in cross section, somewhat like a capital letter X. Smaller tubes, started from horizontal tubes, at an angle of 45 deg. or thereabouts, interspaced so as to pass each other at the centre of the X, and going upwards until they reached the special arrangements—Fig. 11—by which the steam was separated from the water. The pipes continued upwards, and were united by cross tubes from which the steam was taken. This carriage worked extremely well, and went at a very considerable pace; for instance, I remember travelling by it from London to Reading—a distance of about forty-five miles—which on the down journey was performed, from Hyde Park Corner, in $3\frac{1}{4}$ hours, towing a full omnibus behind it. I remember we put up in the inn yard of a coaching house—the name of which I have forgotten—but we had to select this yard because it had gates at each end, and therefore we could get out without having to turn round in the yard. I presume Messrs. Maudslay simply followed directions; but, however this may be, the driving wheels of the traction engine were both of them keyed on to the shaft hard and fast, as though they had been the paddle wheels of a steamer, with the result that it was impossible to make a curve of a small radius; and I remember the right angle turn from the street into the inn yard was only made by a succession of backings and fillings, and my impression is that, even with these, we did not accomplish the right angle bend without sacrificing one of the gate posts. We left Reading, I think, about three o'clock in the afternoon; but the return journey was not done nearly so quickly. The stoker, although he had dined, was fatigued, and he allowed the fire-bars to become clinkered. Most of the passengers, I being of the number, tired of sitting inside an omnibus—remember there were no garden seats in those days, nor even "knife-boards"—came outside, and sat along the edge of the roof all round, like undertakers' men on a hearse. How we held on I don't remember, but we arrived at Hyde Park Corner in the height of the season, covered with soot and blacks that we had received from the funnel. I doubt whether this traction engine—for such it was—worked more than experimentally for one or two seasons.

FIC. 13



A single figure—Fig. 12—which will be sufficient for the purpose, shows the boiler of Messrs. Summers and Ogle's invention. It is strictly a water-tube boiler. The tubes are vertical, and have each an internal tube, giving therefore an annular water space. The external vertical tubes are connected at their top and bottom in transverse tubes, which, I believe, were of a ⊂⊃ section, the lower ones to make the water connection, the upper ones to make the steam connection, while the internal tubes served as stays to join the vertical and horizontal tubes together. This boiler was made of charcoal iron, was proved to 364lb. on the square inch, and ran at 240. The boiler weighed $8\frac{1}{2}$ cwt., and had 245ft. of heating surface, including the portion which was occupied by the steam. The iron was $\frac{1}{10}$in. thick. This coach worked very successfully, in a variety of long and short journeys, but, like all the rest, was eventually abandoned.

Fig. 13 gives a drawing of Maceroni and Squire's boiler. It will be seen to be practically Summers and Ogle's boiler, that is to say, vertical water-tubes, but with the internal tubes omitted, and with the side tubes longer than the tubes in the middle, so as to form a partial external wall to the fire-place. Colonel Maceroni was a powerful man with his pen, and those who are interested in the subject of steam locomotion, and are willing to take it from Colonel Maceroni's point of view, are referred to a pamphlet, published by Effingham Wilson, Royal Exchange, and George Herbert, Cheapside, in 1835. There is another pamphlet by Maceroni, I believe, in the following year, called "Maceroni *versus* The Mechanics' Magazine," which may interest students of the subject. This carriage ran very successfully, but I am obliged to close the account of it as usual by saying that it was eventually abandoned.

Fig. 14 shows one construction of the boiler of Church's coach. The fire was made in a water jacketed horizontal portion of the boiler, which at its higher end carried a vertical cylinder having a bottom tube plate through which rose a number of vertical tubes, which, at their top ends, as I remember, was said at the time turned over and outwards like the supports of the ribs of an umbrella, and thus were enabled to pierce the sides of the vertical boiler and to obtain access for the products of combustion which had passed through them to a circular flue space surrounding the vertical part of the boiler. Fig. 15 shows the alternative plan. In this instance the vertical part of the boiler had an internal cylinder, leaving only a thin annular water space. Near the bottom of this inner cylinder small tubes issued, and were bent upwards so as to rise vertically through the top plate of the cylinder; in fact they were like the tubes of Fig. 1 turned upside down. These were true water tubes. The products of combustion arose between these tubes, and escaped by outlets made through the annular water space into the circular flue, which, as in the previous instance, surrounded the boiler. My recollection is that these boilers, or one of them, was put into a coach—or coaches—which actually ran, but I cannot find any particulars of the journeys.

There is a drawing of Griffith's carriage, which was constructed by Messrs. Bramah—for Mr. Griffith—at page 241 of the 1st volume of Limberd's "Mirror," 15th February, 1823. The carriage is stated to weigh 3½ tons, and was destined to carry 3 tons of merchandise, but I have no account of its running. Fig. 16 is a transverse section of the boiler, which consisted of two flat vertical water chambers, placed one on each side of the fire, and connected together by horizontal water tubes—2ft. long and 1½in. in diameter—of which there were 114. The boiler never could be kept tight, and the whole thing was a failure.

The last steam coach of which I intend to give any description is Scott Russell's. I wish I could give you a drawing of the boiler, but I cannot. As many as seven or eight were built to run between Glasgow and Paisley. These coaches had been running some time when, on the 29th July, 1834, one of them exploded, as it was starting from the Half-way House. Three persons were killed, practically on the spot, and, I believe, two or three of the wounded died afterwards. Mr. Scott Russell did not take out any patent for his boiler except in this sense, that he patented a cubical vessel, made of extremely thin flat sides, but strengthened by innumerable tie-rods, going from side to side. I believe he suggested one for each square inch. He shows no other drawing than this typical vessel, but says, in effect, it would be easy to apply his principle, when flues, &c., are introduced for the purpose of employing the vessel as a boiler. I believe this construction was adopted in the coaches before mentioned. After this explosion, two of the coaches were sent to London. I saw one of them under way. I believe I rode by it. According to my recollection the steam pressure was much reduced, and the speed, I believe, hardly exceeded a walking pace. It is said that one of these boilers burst in Oxford-street, but I did not see it, nor did I know much about it. No one appears to have been injured. The terrible accident at Glasgow had a very damaging effect upon the progress of steam carriages on common roads.

My last reminiscence of a passenger steam carriage on common roads is a comparatively recent one; I refer to the carriage constructed by that most able mechanic, the late Mr. Loftus Perkins. This was purely experimental; it carried only two or three persons. The boiler was the well-known "Perkins" water-tube boiler; the engines were compound, and with the boiler were carried on the framing of the single-steering wheel—it was a three-wheeled vehicle—which was also the driving-wheel, so that the crank shaft was always normal to the direction in which the carriage was going. When speaking of Hancock, I gave him the credit for being the introducer of diminishing "priming" by the use of very small steam pipes. Perkins, with this high-pressure steam of some 600 lb., carried this principle to a still greater extent, and he was in the habit of wearing on his watch chain a piece of pipe having a bore of only ⅛in., through which he had taken the steam for 40-horse power. I am informed, by a letter from Mr. Perkins' son, that this engine is still in use at the Gypsum Works, near Battle.

I do not make any reference to Nairn's carriage, which ran for a long while between Edinburgh and Leith. I do not refer to this because, although no doubt it is one of *my* reminiscences, it is one of so recent a date that it must be included among *your* reminiscences. Neither do I propose to enter into the description of the competition among the self-moving road vehicles in France, which is now taking place, but I am glad to see from the illustrations in the technical papers that the French have appreciated the desirability—indeed, the need—of constructing the vehicles in a manner that should not shock the susceptibility of horses, and, as one who is and always has been much interested in this subject of steam locomotion on common roads, I am very glad to find that it has been taken up by our neighbours, who, having regard to their great engineering ability and their consummate taste, should of all people be likely to obtain a successful result.

---

South Kensington Museum.—We have received the forty-first report of the Department of Science and Art. It contains, among much other information, a statement of the yearly attendances at the South Kensington Museum from the opening of the museum in 1857 to 1893. The total from June, 1857, is 31,805,642, and the number for 1893, 1,174,211. The number of readers attending the Science and Education Library in 1893 was 18,087. The number of readers in the Art Library in 1893 was 22,951. The report also mentions some of the principal purchases made for the museum during the past year. As regarded science instruction, Lord Rosebery and Mr. Acland say:—"In some subjects of science aided by the Department we are of opinion that the instruction given is not sufficiently practical. Although the Department has endeavoured with the staff which has been up till now at its command to insist as far as possible on practical work, yet to test its efficiency has been beyond its power except by examination in the Honours Stage of some few subjects."

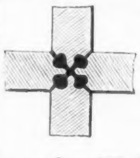
## WELDLESS ROLLED CHAINS.—THE KLATTE PROCESS.

The production of weldless chains is a problem which has occupied the time and taxed the brains of many inventors, but hitherto without any very striking practical results. Perhaps the best known attempt in this direction is that of Oury, who patented in 1881 a process for making chains out of iron or steel bars of cross section by punching and forging in dies, obviously a very costly method.

Mr. O. Klatte, a German engineer, has, however, at length solved the problem in question in a manner which appears likely to prove practically successful, not merely mechanically but commercially. The main process in Mr. Klatte's method is one of rolling, and the preliminary form is also a bar of cross (+) section.

After the bar has passed through the chain rolls it still remains a continuous bar, but has been squeezed by the rolls into such a shape that only the removal of a thin web inside and between the links is required in order to convert the rigid bar into a flexible chain. In the chain bar so formed the links are not in contact with each other—as they would be in a loaded chain—but are separated by the web, so that the length of the bar is less than that of the finished chain.

When the chain bar is cold, the web is removed by punching, and the chain thus produced is cleaned up by emery wheels or in a revolving drum. The links, as they leave the rolls, have generally a somewhat greater width in proportion to length than is required. The final operation, therefore, consists in pressing the links to their final proportions. For this purpose the chain is reheated to a cherry red, and passes through a press which reduces each link to the desired width. The whole process is entirely mechanical, with the exception of such dressing as is always necessary with rolled material. The chain bar is produced by a single passage between four rolls, of which the axes of one pair are perpendicular to those of the other pair. The contact surfaces of each roll are bevelled like a double bevel wheel, so that the lines of contact between the four rolls form an × in a manner which will be clear from the accompanying sketch. Chains of 1in. diameter have already been made by Mr. Klatte's process, and the production of heavier chains is merely a question of power and strength of parts. In practice both + bars and chain bars would be rolled in one heat, a new method of rolling being also employed for the former. The velocity of the chain rolls ranges from 10ft. to 20ft. per second, according to the dimensions of the chain.



A subsidiary advantages of the process is that the links of a chain can be made of greater thickness at the ends than in the middle, in accordance with the requirements of strength, and also in order to allow for wear.

All the experiments have been carried out at the Germania Ironworks—Walzwerk Germania—in Neuwied on the Rhine. We shall shortly publish details of Mr. Klatte's process, which, it may be mentioned, has been very favourably reported upon by experts in Germany.

## COMMERCIAL DISHONESTY AND SANITARY NEGLECT.

A typical example of the low state of commercial morality, and the indifference to sanitary requirements prevailing in Eastern countries, is reported from Resht, a town of between 30,000 and 40,000 inhabitants in the Persian Province of Ghilan. Business is not carried on in Persia on sound principles, chiefly owing to the excessive competition among native traders. The terms of credit are unusually long, cotton goods being generally paid for after the expiration of at least eight or ten months. Native merchants of Tabreez, who buy cotton goods at two and three years' credit from English firms in that city, arrive with their unpaid for goods at Resht, sell them at a loss, and purchase other articles, a number of these merchants passing through the bankruptcy court—or what stands for it—before the three years' credit has elapsed. The Manchester business is chiefly in the hands of men who live on the verge of bankruptcy, and are reduced to that state by the slightest disturbance in the trade. These bankruptcies are nearly all fraudulent, effected with perfect impunity, and are managed in such a way as to be eventually profitable to the bankrupts, who pay 5 or 6 per cent., or even less, and are then discharged. A trader who has recently been bankrupt is considered a good man to do business with for the next few years. As a rule it is not advisable to go before the local courts to enforce a debt, it being usually more economical in the long run to accept any private composition that can be agreed on and obtained.*

The town of Resht has no sanitary arrangements, and everything tends in the opposite direction. There are not any sewers, and although gutters exist in some streets they are worse than useless, having no means of carrying away the accumulated water, and consequently they are oftener than not full of a stagnant green liquid. The rubbish out of kitchens, and stuff that in England goes into the dustbin, here is thrown out in certain corners of streets and open spaces, where it is allowed to accumulate. The privies existing in each house are mere wells varying in depth, and having no exits. Drinking water is obtained from wells sunk within ten to twenty yards of these privies, according to the space occupied by each house and its grounds, but a good deal is left to chance. Water is found at from 5ft. to 10ft. from the surface. Ponds have been artificially made where water out of the street gutters accumulates, and when in winter it freezes, this filthy muddy water is turned into ice, and collected in the ice houses for consumption in the following summer. Bacteriologists would have ample employment in examining the ice universally consumed here, and would probably be horrified at the results. When the cholera broke out in the summer of 1892, and came to Resht *viâ* Enzelli from a Caspian port, resulting in thousands of deaths both in the town of Resht and province of Ghilan, no quarantine arrangements were made in time, and when orders did eventually come from Tehran, and the Resht authorities endeavoured to put them in execution, the arrangements for housing the persons undergoing quarantine were so inadequate and defective, that the Russian consul refused to permit persons under his protection to be subjected to it.

## LETTERS TO THE EDITOR.

*(We do not hold ourselves responsible for the opinions of our correspondents.)*

### THE CHICAGO STRIKE.

Sir,—Your recent leader on the above subject, and the questions asked, and the shrewd suggestions therein, must be my excuse for the following non-technical letter, from the pen of an entirely disinterested observer on the spot. And first, in justice to the real citizens of America, permit me to protest against your, and the *Times*, describing such as "The American Strike," for though Chicago be American, America is not necessarily Chicago. And to this happy fact the speedy and utter collapse of the strike is mainly due. As to California, she is probably in the same relation to America proper, and anyhow, even her "moral effect" does not reach so far inland as to affect Chicago.

You show your own grasp of the situation by properly eliminating the Pullman lockout from the second stage of the disturbances here, and then speculate as to the cause and nature of such disturbance. Well, Sir, the cause was undoubtedly the general spirit of discontent, mistrust, and widespread actual want, that is so alarmingly apparent here; and the nature of it was much more akin to "an insurrection"—to quote your own words—than to "a labour question of the normal kind." Still, though the "insurrectionists"—and this term, obviously, does not necessarily include "strikers" *per se*—were largely composed of Poles, Hungarians, Bohemians, Scandinavians, with a sprinkling of Dutch, Germans, and Italians, it by no means follows that they were rebelling "against the Americans," as you thought they might possibly be. Not but what in all large cities the American citizen is beginning to feel much as did the ancient Egyptian, when the Israelites increased and multiplied so steadily. No, these poor fellows of the baser sort were the rather giving a too practical expression of their discontent and disappointment, at "the cussedness of things in general." But you still ask, why railways in particular were assaulted, and the answer is that, owing to the Pullman Railway conspiracy, railways happened to be the most available victim, and withal they are so much more easily and safely attacked, by reason of their extent and unguardedness, whereas the sacking of a factory or the raiding of a store is an obviously risky procedure where there are any police about, nor are its effects so far reaching. Moreover, most of the "bloated capitalists" are railway stockholders more or less. I fancy some of your London bond-holders would sympathise on this score just now.

To return now to the strike itself, you say, "Unless matters had been planned beforehand, the affair could not have attained its present magnificent proportions." *au contraire*, Sir, had this man Debs—a quondam fireman on the Wabash line, now enjoying £600 per annum for most incompetent administration—been capable of planning beforehand, he would have saved himself the stinging humiliation of a magnificent fiasco. Whereas now he is on trial for inciting to the infringement of interstate commerce laws and delay of mail transit, his only consolation is that this city has a nice little bill to pay to the railway companies for damage done. In other words, there would have been no strike had the Railway Union—his pet creation, which in return has failed him miserably—possessed a more competent and less priggish head; for it stands to reason that no railway strike can be called "general," nor command any success, that fails to include the intellectual departments of engine-drivers and conductors. Since, therefore, these two orders most praiseworthily refused to take up the Pullman quarrel, their action "dammed the show" from the outset, and almost immediately it was found that in the more sober and civilised east no hands at all would obey the mandate of this young upstart Debs.

Towards the end of your article you hardly give the central Government the credit it deserves. So far from being supine, it sent the troops here, not only without a feeble threat of so doing, as would have happened under Mr. Asquith, but positively without being asked—except by its own Post-office department—and when its troops went into action there was none of that milk-and-watery fooling with nervous magistrates and effeminate Riot Acts that so unhappily mars the moral effect of "the assistance of the military" in England.

There is much that calls for comment in your most suggestive article, but I must remember I am writing to The Engineer, and must accordingly keep to the railways only. But, Sir, may I suggest that you missed a point in not working into your article a most opportune allusion to Lord Salisbury's "Immigration of Aliens" Bill, which Lord Rosebery treated in so cavalier a style, a style he would, I trow, modify had he seen the handiwork of aliens here during the strike, and which might in some degree happen in London itself, quite apart from anarchy *per se*.

Michigan Avenue, Chicago, Ill., July 28th. C. W. V.

### PATENT SPECIFICATIONS DEPARTMENT, SOUTH KENSINGTON MUSEUM.

Sir,—I wonder how many of the London readers of The Engineer know of the existence of the above? I fear very few. Having the good fortune to unearth it the other evening, after innumerable turns to right and left among plaster casts, &c., I looked over the visitors' book and found to my surprise that during the whole month of July there were not two dozen signatures. This is not the case at the Patent-office in Chancery-lane; no matter when I go there, the place is reasonably well filled, the visitors' book also testifies to the same. What, then, is the reason of so few availing themselves of its advantages? I think good tough "Red tape." The books, specifications, &c., are stuck into the very darkest corner of the reading-room, there is barely sufficient room given to turn round in. On entering the Museum no indication is given as to the direction you are to pursue—of course I take it for granted that everybody knows that the publications are to be found somewhere in the building. Why is there not a prominent notice inside the entrance giving full directions how to proceed? It looks to me as if the heads of the department regarded it as an eyesore, and, as such, kept it as much as possible in the background—an evil that had to be tolerated, but with the very worst grace. I consider that such a place cannot be put too prominently forward. How many more hundreds of our working classes would avail themselves of it if there were not so many obstacles placed in their way? I cannot speak too highly of the courtesy and attention of the assistant in charge, he doing everything in his power to give any information desired; but, from the number of books that were passing through his hands, I should say he has quite enough to do. I was much struck with the knocking of the electric light engines in some adjoining building; the engineer in charge ought to be a proud man to produce such a knock. I have never heard its like in any other station, it is quite unique. Would it be worth suggesting that the engines and dynamos be placed in a building to which the public had access? A gallery could be used, or railings erected to keep them out of the engineer's way. How many students would then derive both pleasure and information from watching them? Thamis.

August 1st.

### ENGINEERS AND ARCHITECTS.

Sir,—The only purpose, we take it, which was originally intended to be served by an architect's certificate was that of certifying that the work done by a contractor had been completed in a satisfactory manner.

During the last two or three years, it seems to us, a custom has grown up of making the certificates serve another purpose, which in our opinion is very unfair to the contractor; that is to say, when for any reason the customer is unable or unwilling to make payment, the architect's certificate is withheld, and in its absence, under the conditions of many contracts, the contractor is, of course, powerless to take legal proceedings, or at the very best he runs a considerable risk of failure.

During the present year we have had not less than five cases in which certificates have been withheld. In none of them was there any dispute as to the work not having been finished in a satisfactory manner. Had this been otherwise there would, of course, be no point in our dispute.

1. In the first instance, the architect distinctly told us in confidence that the company employing him had directed him to issue no more certificates till they had funds in hand to meet them.

2. In the second case the customer repeatedly expressed his willingness to pay as soon as we got the certificate. The architect did not refuse in so many words to issue the certificate, but he did not reply to our letters, and was always out when we called. In this instance, as we had not the slightest evidence of collusion—although, of course, we could not but suspect it—we could do absolutely nothing.

3. In the third instance the architect promised to issue a certificate if we would give him a commission, and, upon our declining to do this, he took no further notice of our requests.

4. In the fourth case the work was done in a very great hurry, and at much inconvenience to ourselves; the architects were an old-established and most respected firm. They did not refuse the certificate, but delayed from time to time, until six months had elapsed when it was issued. When we produced the document we were informed that the proprietors of the building were in liquidation, and that an application had been made for an order of the Court restraining creditors.

5. In this instance—the only one of the five in which there was a dispute of any kind—a question arose in connection with a trifling sum charged for extras. Owing to this the architect refused a written certificate of the completion of the contract, although he stated he would issue one as soon as the account was adjusted. The proprietors, however, refused to pay anything, owing to the certificate not being issued. In this last instance we shall probably succeed in getting our money, but nothing could be done in regard to the other four; and our purpose in writing is to ask your readers if they are experienced in similar difficulties in connection with architects' certificates.

We do not wish our names to be published for the present moment, for obvious reasons; but you, Sir, will be able to confirm the fact that we have been many years in business. Down to recent times we have never experienced any difficulty, and it seems to us that a new custom must be growing up, on the part of proprietors of buildings, of requesting architects to withhold certificates for financial reasons only. If this is the case, we think that concerted action by a few of the larger firms would be of service. Unless our own experience is unique, we are of opinion that it is absolutely necessary that something should be done in the matter, unless contractors are content to submit to considerable losses.

When a shaky united company is the customer, a delay in certifying for the work done is often an effective weapon in defeating the contractor. Mechanical Engineers.

London, August 11th.

### BRIGHTON BEACH.

Sir,—As the inventor of the open groynes system and the stout opponent of solid or large groynes, I have been much interested in reading your article on this subject. You call attention to the different systems that have been adopted by the two towns, Hove relying mainly on its sea-wall, and Brighton on its groynes, and after pointing out that both systems have their serious drawbacks, you suggest that some improved method might be designed.

The great desideratum seems to be to prevent the washing away of the foreshore, while at the same time artificial interference should be avoided as much as possible. For this reason I desire to again call attention to open groynes as providing just what is required to overcome the difficulties you have pointed out. This is no question of opinion, as it is now more than ten years since I erected some on this system, and having examined them within the last fortnight, I am able to describe the result of their working. A number of these groynes, which consist of uprights driven into the foreshore, having horizontal gratings attached to them, after having been erected for over ten years, are now so entirely covered with shingle that only the tops of the uprights and a few isolated parts of the top bar of the gratings can be seen.

Another instance is that within the last twelve months an embankment which has been made along the seashore and faced with rubble stone was seriously assailed by the sea. To protect it open groynes were fixed at right angles to the embankment at intervals along about half a mile; the damage was stopped, and at the present time the gratings are filled with shingle. I think the above may be taken as ample evidence to prove that open groynes do trap and retain shingle, and that, therefore, if fixed in suitable positions they can be relied up to protect the Brighton foreshore, without the serious expense and disadvantages of a sea-wall or concrete groynes. A. Dowson.

39, Old Queen-street, Westminster.

### THE EIGHT HOURS' DAY IN PORTSMOUTH DOCKYARD.

Sir,—In reply to "Keppel" *re* eight hours' day in Portsmouth dockyard. No doubt it would interest a certain faction of the community to know that the dockyard men are dissatisfied with their lot, and also to know that they really have to work all their time in the yard. Surely Keppel must refer to the olden times, when the men commenced work at six o'clock, and worked until six o'clock at night, when they were allowed a stopping time for meals.

But it is of far greater interest to the dockyard men concerned to enjoy the privilege of an eight hours' day, than to receive sympathy from Keppel for the dissatisfaction he supposes to exist. This has been the ideal of a working day for many years amongst the English mechanics, and which they hope to enjoy for many years to come. As for working their whole time, this would appear to cast a very serious reflection on the supervision of the officers. It is nonsense to say that the men are dissatisfied because they have to work forty-eight hours instead of fifty-one hours per week for the same pay.

It is only natural that the men would be expected by their employers to show a little more increased diligence in their work, for which they are amply compensated in the shorter hours. The dockyard work will no doubt bear a very favourable comparison at any time with outside work in point of speed and workmanship.

Perhaps the dissatisfaction heard of by Keppel comes from one of those good people who always have a grievance, and always willing to air it when he can find a willing listener. It is hardly to be expected that unanimity of opinion to exist on any topic amongst a number of men of all grades and classes numbering between 6000 and 7000 men.

The question of apprentices, &c., is foreign to the subject. Doubtless the change is an improvement, but cannot see what this has to do with the Church or its work; and if Keppel is as good a supporter of that institution as he is for the interest of the working class, it would be a benefit perhaps to both parties to hear his experience. A Satisfied Dockyard Man.

Portsmouth, August 9th.

## THE GREAT NORTHERN TRADE ROUTE.

The present disturbance in the Far East involves questions of the largest moment to England. England's life is her trade. The scope of these questions is hinted by the condition in which the present affair has surprised her cable communications with the Chinese seas. It is at last realised how dependent these are upon the attitude of nations which may not be friendly. Hence the prompt revival of the proposal for a direct cable between British Columbia and those coasts. But this suggestion brings into strong relief the still greater need of adequate naval stations north of Hong Kong. The tone of the Russian press, if its utterance can be deemed inspired, shows that such a station can be acquired only by understanding with the Czar or through a war with him. The last contingency is not to be thought of unless in the last resort. It follows that England must consent to go on with her enormous China trade under perpetual menace, or must agree with the Russian as to the acquisition of a naval station.

Except for sentimental notions of prestige, there is no obvious reason why the three naval Powers, England, France and Russia, should not agree on three points suitable to the needs of each respectively and take possession of them. Their natural relative positions would seem to be: the southernmost to France; the middle one, somewhere about the latitude of Shanghai, to England, and the northernmost to Russia. They would thus be acquired at the cost of China and Japan, who would have no alternative but to submit. The Russian would doubtless consent to take his foothold in Corea, where his establishing himself would disturb no existing trade interests. Even if in time his position there should result in his dominating and developing that peninsula, nobody would be injured, and nobody is in position to complain in anticipation. In short, such an arrangement would merely transfer to Russia the rôle which Japan has proposed to herself in her present intervention in that country. Corea would still be opened and reduced to the general use of mankind. Only the work would be under the auspices of the Split Eagle instead of those of the Risen Sun.

The alternative is twofold: first, the three naval Powers may combine to put down Japan and restore the *status quo ante*. This, it must be allowed, is the first impulse of the professional diplomatist. It settles nothing, but it avoids the enormous embarrassment of constructive measures. It is the instinct of your right diplomatist not to cure, but to cataplasm—to cover up, to hide away, and leave the poison to nature. The other alternative is to fall to and fight it out. The last will never be resorted to by a trading nation till it is cornered. Excluding this last, then, as the least probable of the three modes of settlement, we have to observe that a restoration of the *status quo* leaves England with her prestige fatally damaged in the East. At this moment it is plain as a pikestaff to the whole world that without a Northern naval station she is utterly unprepared to sustain a naval conflict in the China seas. It is palpable that a time must come when Russia, even should she secure no such station south of Vladivostock, will hold England's trade at her mercy.

It is impossible that English statesmen should fail to see what is now palpable to all the world beside. The situation for them, it must be allowed, is one of difficulty and embarrassment. To realise just how embarrassing it is a moment's attention must be given to the Canada route as a great through trade route. A New York convention is at this moment considering the enlargement of the Erie Canal. Up almost to to-day the enlargement of this canal was a matter of concern to our West. It has ceased to be so in consequence of the enlargement of the Canadian canals which now furnish the sufficient competition to tide water that accomplishes the purpose of keeping rail rates down. The trade thus created is leading to the establishment of new Canadian steam lines across both oceans, the Atlantic and the Pacific. These lines, with the railway that links them, constitute the shortest possible line of communication between Europe and Eastern Asia. It is the line nearest to a great circle. It is the line which nature and the laws of geometry have marked out as excluding successful competition.

In this light it is fully appreciated both by Canada and by the mother-country. It is, in their eye, the great highway of the future. Yet, unless England secure a naval station somewhere north of Hong Kong, this vital artery must exist subject to the forbearance and goodwill of rival Powers. If, indeed, England is now willing to remain in a position such as this, it will be a marked departure from the policy and the traditions to which her present position is due. Thus the rising truculence in the tone of her press seems fully accounted for. England perforce must grab something out of the present disturbance or her position is far worse than before. Its weakness has been revealed: and not alone that, but the vantage held by the Russian is displayed to the view and conciousness—Asiatic and European alike.—*New York Evening Sun.*

## TENDERS.

The following are the results of an invitation to tender for twenty-four engines and tenders for the Egyptian Government Railways in June, 1894:—

| | £ |
|---|---|
| Franco Belge, Belgium | 40,553 |
| Neilson, Scotland | 41,280 |
| G. Ansaldo and Company, Italy | 43,520 |
| Société des Forges | 44,121 |
| Cockerill, Belgium | 44,121 |
| Marcinelle and Couillet, Belgium | 44,612 |
| Sharp, Stewart and Company, Scotland | 46,560 |
| Austro-Hungary, Austria | 47,476 |
| Dübs, Scotland | 47,760 |
| Sachsche, Germany | 48,742 |
| Henschell and Son, Germany | 49,390 |
| Hanoverische, Germany | 49,423 |
| Suise, Switzerland | 49,842 |
| Vulcan, Germany | 49,934 |
| Vienna, Austria | 50,246 |
| Actien Gesellschaft, Austria | 50,373 |
| Machinen Fabrik, Austria | 50,420 |
| Hohenzollern, Germany | 50,601 |
| Locomotive Fabrik | 50,895 |
| Alsacienne, Germany | 51,085 |
| Beyer, Peacock, England | 51,500 |
| Metallurgique, Belgium | 51,844 |
| Stephenson, England | 53,256 |
| Breda, Italy | 54,313 |
| Kitson, England | 54,480 |
| Berlin, Germany | 55,488 |
| Hawthorn, Leslie, England | 60,600 |

**Railways in Norway and Sweden.**—According to recent Foreign-office reports from Norway and Sweden, it is expected the line of railway connecting Porsgrund and Brevig will be finished this year. This line will be a great acquisition, not only to the particular district, but also to all parts situated on the south coast, as more direct communication will be opened up with Christiania. The town of Stavanger has voted a sum of money towards the continuation of the Stavanger-Egersund Railway to Flekkefjord. The completion of the Swedish railway system is progressing steadily, and the direct line being constructed from the manufacturing town of Boros to Gothenberg, is expected to increase the trade of the latter place. Rails, which had hitherto always been imported from Great Britain, had lately been brought from Belgium for a narrow-gauge railway under construction at Uddevalla. A narrow-gauge railway, twenty-two miles in length, is being constructed from the port of Falkenberg to the interior. A large district has been opened to the trade of Helsingborg by the opening of the Scania-Smeland Railway, from the Astorp Station on the Helsingborg-Hessleholm Railway to Markaryd, a village in the province of Smoland. The railway line from Landserora to Kjeflinge was opened last summer, and a regular steamship line to Hamburg started in the course of the year, thus further improving the existing good communications both by land and sea. The Malmö-Tomelilla Railway has been opened to traffic, and by joining the Cimbrisbamn Tomelilla Railway forms a line from west to east through the entire province of Scunia. A new railway, the Malmö-Gnarp—the seventh in order terminating at Malmö—is being constructed, and will probably be opened for traffic this year. Two railways, the Ystad Gärnäs and the Klagstorp-Rydsgord, are being constructed in the district of Ystad, and expected to be opened this year.

## THE DESIGN OF MAIL STEAMERS, WITH SPECIAL REFERENCE TO THEIR USE FOR WAR PURPOSES.[*]

By Professor J. H. BILES, M. Inst. Naval Architects.

*(Concluded from page 129.)*

IT is hardly necessary to say that for war purposes twin-screws should be adopted, but their adoption renders it more easy and more necessary to adopt short strokes and high revolutions, as it is only by narrowing the base of the engines that good space can be got abreast of them for coal protection. The one point in which a mail steamer may be expected to be superior to a warship is in the efficiency of her machinery. The every-day use of it at its maximum power, under the pressure of commercial necessities, causes it to attain and maintain a high state of efficiency, which is difficult of attainment under other circumstances. This high efficiency exists also in the engine-room staff, and it may therefore be fairly assumed that the machinery of a mail steamer in constant service is more capable of developing its best results than in that of a warship. It is therefore necessary that this machinery should be designed so as to be as well protected as possible in war time, and not in such disregard of this consideration as to expose important parts of it to rapid and easy destruction, as is the case in tandem engines. The stability of these steamers, measured by metacentric height, is of importance in dealing with the question of protection. For sea-going purposes, in an intact condition, one foot of metacentric height is probably sufficient. In vessels with double bottoms any loss of stability due to burning out coal can be made good by the use of water ballast. But for war purposes, on account of the possible flooding of some compartments, it is desirable to have a much greater metacentric height than that stated. If the weight of the cargo that mail steamers carry is replaced by coal, its centre of gravity will generally be higher than that of the cargo, as it will be placed for protection in the vicinity of the water-line. It will be liable to be used, but the use of this part of the total coal will not sensibly affect the stability of the vessel in the intact condition. If any compartments containing coal are flooded in the vicinity of the water-line, there will be some stability maintained by the water-displacing power of the coal; so that even if the centre of gravity of the ship when intact is not affected much by using the coal, its stability in a flooded condition will be. This points to the necessity of having either a considerable metacentric height in fully loaded condition, or of having large water-ballast tanks, so as to vary the height of the centre of gravity as coal is used. Vessels without water-ballast tanks will be at a considerable disadvantage compared with those having them, as they must certainly either carry something like pig iron for ballast, or must be content with a much smaller amount of consumable coal in the ship. Hence it is necessary for war purposes that a mail steamer should have large ballast tanks. Large initial stability is of great value in enabling a vessel to retain some positive stability with a large number of compartments flooded, but it is a disadvantage in the intact condition unless accompanied by bilge keels. These seem, therefore, to be a necessity in a steamer for war purposes.

In considering the possibility of protecting a mail steamer by armour, it must be assumed that this armour is not carried in time of peace. Consequently this armour must be arranged in such a way that it can be readily shipped in time of war If the amount of weight at disposal is sufficient to give a considerable amount of protection, it seems necessary to put it on the side of the ship as vertical armour. The amount of subdivision in a mail steamer cannot be as great in the vicinity of the water-line as it can be in a warship, and less reliance can be placed upon the subdivision to keep the ship in a fighting condition. Hence the necessity for keeping the water out of these compartments. Further, it would be very difficult to ship in a short time large quantities of internal protective deck armour, even if it were practicable to arrange in the original building of the structure a deck in a suitable position and with suitable support. On the contrary, the fitting of side armour upon previously prepared supports would be comparatively easy. The armour and backing should be fitted to the ship while she is building, and then removed; the backing being secured to the armour, so that both might be put upon the ship at one lift, when she is preparing for war purposes.

Fig. 3, page 112, shows a midship section, arrangedin a suitable manner for carrying armour. When the armour is not carried the sharp corners of the shelves would be filled in with wood, as shown on the drawing. The armour belt is shown 5ft. above and 5ft. below the load line. In ordinary times the breadth of the water-line would be less than the full breadth of the ship, and the stability would be less than in the ordinary form. This variation is in the direction of small stability when on ordinary service, with a possibility of increasing it when on war service. This is in the direction already indicated as desirable. If for any reason it is desirable not to have a recess in the side in ordinary service, the recess may be filled in partly by the teak backing and partly by other timber, which would have to be removed in time of war. The outside timber would have to be sheathed with plates, say, ¼in. thick, screwed on to the wood. This would make a good working side in the vicinity of the water-line, where barges usually knock the plating about most. The fitting of transverse armour bulkheads would be more difficult, but with the large hatches common in mail steamers, the plates could be shipped and landed on previously prepared supports. It would generally happen that the belt would be partly above and partly below a deck, so that the work upon the plates of a transverse bulkhead could be done by two separate working parties. There seems to be no great difficulty in arranging for an armour belt which could be fitted during construction, and could be kept in a port where it could be rapidly shipped and fastened in war time.

The deck protection could be provided by fitting what are known as splinter gratings on the top of the ordinary steel or wood deck. These splinter gratings would have to be fitted permanently in the funnels, but could be removable elsewhere. In cases where it seemed to be desirable to extend the belt for only a part of the length of the ship, it would be necessary to carry the splinter grating protected deck to the ends of the ship. To make this deck effectual, it would be necessary to make it a water-tight deck, instead of making it of stringers and ties, as is usually the case with a deck at such a low level. The magazines would be below this deck, and in a ship with twin screws probably the best place for these magazines would be between the tunnels; for the water-tight deck, the transverse bulkheads, the tank top, and the tunnel sides, if carried up to the water-tight deck and down to the tank top, would form the necessary water-tight box which usually encloses a magazine. A special trunk could be fitted to act as an ammunition hoist, which would serve as a ventilator in ordinary times. The weight involved in making this trunk 2in. thick—a common thickness for a warship—would only be ten tons for each trunk, and this could be made part of the original structure of the ship, to be always carried in peace or war. It would be advisable to fit a similar water-tight compartment at the fore end of the ship. The space abreast of the two additional fore and aft bulkheads necessary to form this compartment could be used for carrying fresh water in bulk, and the pipes necessary for filling and emptying these compartments could be fitted so as to act as flooding pipes for the magazines. If for any reason it was not desirable to use the space for fresh water, it could be made available for cargo by having two additional hatches, the ordinary middle-line hatch serving to bring the cargo to the level of the water-tight deck. Over the compartments destined to hold magazines, it would be desirable to fit arrangements for readily shipping protective deck plating of, say, 2in. thick. The splinter gratings fitted over the other part of the deck would be here dispensed with. The only other vital part of the ship necessary to consider is the steering gear. In four of the later ships built with the intention of being armed cruisers, the steering gear has been kept below the water-line. In this respect these vessels are as efficient as the best warships, with the difference that there is no deck protection above them. This protection could be formed either by thick plates or splinter gratings over a water-tight deck, either of which could be rapidly put on board in war time, if previously arranged for when the ship is building.

Little need be said about the facility for working guns. The clear deck space of an ordinary mail steamer gives ample room for working as many guns as the number of men available who can handle them would permit. At each end of the ship, on the forecastle and poop, two 9in. guns can be carried and fired without much special preparation, as mail steamers are usually stronger in these parts than warships. It would not be difficult to adapt these structures to carry 9in. guns with their shields. It would also not be difficult to cut ports in a centre bridge-house for carrying either 6in. or 5in. guns; these ports being kept permanently shut when the vessel was on her ordinary service, or used for the ordinary purposes of the ship. The gun stations could be placed almost anywhere, as the cabins and saloons in the upper deck would probably be removed when the vessel was taken up for war purposes. In the part of the upper deck between the poop and bridge-house and forecastle and bridge-house, there is usually ample room for guns. In some of the later vessels the promenade deck is strong enough to carry guns, and it would be preferable always to make this deck suitable for such a purpose, in order to carry the guns at as great a height as is practicable. The amount of extra material necessary to do this would not be great. It would be as easy to fit either submerged or above-water torpedo tubes as it is in a warship, all the fittings except the part attached to the ship's side being removed and placed in store after having been fitted. To make the vessel suitable for war purposes a conning tower would have to be fitted, the support being permanently worked into the vessel. It will be necessary to take account of the weight of the crew and their stores and provisions, the engineers' stores, and possibly a net defence against torpedo attack. Many items of weight, such as cabins and their fittings, could be removed from a mail steamer in war time.

All the foregoing points affect more or less the design of the vessel, and would have to be taken fully into account in preparing the construction drawings. To give definiteness to the suggestions, the extra weights involved have been calculated for a vessel 500ft. by 57ft. by 40ft. They may be summarised as follows:—

(1) Boilers and bunkers arranged so that all coal may be abreast and beams placed in them so that a temporary flat may be fitted at half height in war time. This involves 40 tons of permanent extra weight of bunker bulkheads, but adds considerably to longitudinal strength of ship, so that savings may possibly be effected in other ways to reduce this. The weight of the temporary steel flat will be 30 tons.

(2) Web frames to be made sufficiently wide between main and lower decks, so that they may form the inside line of a further longitudinal subdivision which shall be fitted only in war time. The longitudinal water-tight work at the decks to which this bulkhead would be connected are assumed to be permanently carried. The permanent weight added by this arrangement, if it be adopted for three-fourths of the length of the ship, will be about 25 tons. The temporary or war time bulkhead will weigh about 45 tons.

(3) To prevent a dangerous heel, if a compartment on one side only should be flooded, the corresponding compartments on opposite sides of the ship should be connected by a pipe, so that when one is flooded the other may be also. The permanent additional weight would be 25 tons. The temporary weight would be 15 tons.

(4) Make main transverse bulkheads of ship double, with a space between which can serve as a well. In this space place a steam pump and also a steam ejector. The extra weight due to this arrangement will be about 25 tons.

(5) Increase capacity of double bottom so that greater power to maintain stability in damaged condition may exist. Adding 1ft. to the depth of the double bottom will add 60 tons.

(6) Permanently protect the main steam pipe and mountings by a tube, say, 1½in. thick and 4ft. in diameter, through which the electric light wires, telegraph wires, voice pipes, auxiliary steam pipes, and all things which cause holes to be cut in bulkheads can be carried. Extra weight due to this, 100 tons.

(7) Recess the side for, say, 300ft., so that armour and backing previously fitted may be readily shipped. Extra weight due to the permanent alteration of structure will be about 110 tons. The loss of displacement due to the recess would be about 140 tons on a 27ft. draught. If permanently filled in with wood, the extra weight would be 300 tons. Armour, 8in. thick on side, and 6in. on transverse bulkhead, with backing 6in. thick, carried for 300ft. on the side, will weigh 1300 tons. Displacement 110 tons.

(8) Make deck over boilers and engines, and orlop deck beyond belt water-tight permanently, and temporarily fit either plates or splinter gratings. The permanent extra weight would be about 30 tons. The temporary weight of deck, including a 2in. shield over magazines, will be about 550 tons.

(9) Fit a 12in. conning tower. The extra permanent weight would be about 10 tons. The temporary weight of conning tower and tube to connect communications would be about 100 tons.

(10) Permanent strengthening for, say, two 9·2in., ten 6in. quick-firing guns, and a corresponding number of small quick-firers. This may involve about 40 tons. The weight of the guns and their fittings and ammunition would be about 600 tons.

(11) The fittings peculiar to passenger and cargo carrying could be removed in whole or in part, say 400 tons.

(12) The crew and stores necessary to equip the ship for war would amount to about 350 tons.

Thus we have a permanent addition of about 605 tons to the vessel, which would be a loss of weight-carrying to this amount. In some ships this would mean loss of freight-earning; but in others, whose earnings depend upon measurement goods, it would only involve a small extra expenditure of fuel to drive the heavier vessel. The net additional weight to be carried to equip the vessel for war as described would be about 2590 tons. Such a vessel on 27ft. draught would have about 5800 tons of total weight carrying in ordinary work, without allowing for the permanent additions described above. After allowing for these and the temporary additions, which make in all 3195 tons, there would be available for coal 2700 tons. This amount of coal would enable the vessel to steam at full speed for ten days at full power, or for twenty days at half power, which is about the proportion the Admiralty regulations of two-thirds natural draught power would amount to. The corresponding speeds would be about 19 and 15 knots, and the distances steamed would be 4500 and 7200 knots. Longer distances could be steamed at lower speeds. The extra cost of the structure would not be considerable, in relation to the total cost, and the modification necessary would detract but little from the commercial efficiency of the vessel, beyond the loss of freight-earning due to the loss of weight carrying. It is believed that such a vessel, when fitted with her removable war equipment, would, for gun, torpedo, and protective capabilities, be little, if any, inferior to our first-class cruisers, while in speed and coal endurance it is believed that such a ship would be superior.

It may be objected that the large size of these vessels makes them unhandy fer manœuvring, but this is largely a matter of rudder area; and when we know that vessels larger than the size chosen can turn a complete circle in five minutes, much of the force of this objection is removed. The loss of money earning in such a vessel due to the permanent additions to structure would vary in different trades. Where the trade is with cargoes so light that there is no chance of the vessel being made too deep in the water by these additions, it is probable that the extra working expenses would be about £2000 per year. The first cost of these permanent additions would be about £25,000, representing about £4000 per year for interest, insurance, and depreciation. In the trades where deadweight is of importance the loss of 600 tons of cargo is a more serious matter. It is difficult for a shipowner to say what loss in money is likely to be involved by such a permanent load, but it is probable that £15,000 per year would be accepted as a solatium for this loss, and this, with the £4000 due to extra first cost, would make a total contribution to the shipowner of £19,000 per year in excess of the subsidy which would be paid for an ordinary mail steamer. The cost of the armour and other protection would be about £160,000, and the guns and mountings £60,000. The interest on this sum at 5 per cent. is £11,000 per annum. This sum, added to the £19,000 above, makes a total of £30,000 per year; for which sum, in addition to the present subsidy, the country would have an efficient warship of great power, instead of a mere auxiliary to a fleet.

This paper has exceeded the intended limits, or something would have been said about the smaller classes of high-speed mail steamers, in whose designs considerable modifications will generally have to be made if the best use is to be got from them in war time. The object in view in writing this paper will have been gained if attention is directed to the great inherent power in our mail steamers to become real ships of war in time of need.

DUCKHAM'S PNEUMATIC GRAIN ELEVATOR AND CONVEYOR.—In our impression of the 20th ult. we published an illustrated description of the Mark Lane, and referred to an elevator then being completed by the East Ferry-road Engineering Works Company for the London Grain Elevator Company. An official trial of this machine was made on the 1st inst., when buckwheat was lifted 37ft. and delivered from barge to barge through an 8in. suction at the rate of ninety-six tons per hour, and through two 8in. suctions simultaneously at a total rate of 180 tons per hour. This was considerably in excess of the estimated efficiency, and was more than could be dealt with by the experienced men the owners employed to weigh on delivery. In the afternoon there was an exhibition of the elevator in operation in the presence of seventy or eighty influential shipowners—merchants and others interested in and having experience in the shipment, transport, discharge, and handling of grain. The Baltic did remarkable work and called forth great praise from the visitors, as did also Mr. Duckham's process for loading grain into ships by the combination of the compressed air and the vacuum process in use on the Mark Lane and Baltic. The Baltic will forthwith take its place at the Royal Albert Dock for discharging some of the American liners arriving there with large cargoes of wheat and maize.

---

* Re-appointed.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

The improvement in the Glasgow and Middlesbrough iron markets has assisted business at the local exchanges this week, and the intelligence that the American Tariff Bill has passed has helped to produce a more buoyant feeling among ironmasters. Great hopes are entertained that the long-expected revival may now put in an appearance. In some quarters this expectation amounts to an almost certainty. A circumstance which would seem to partly warrant these views is a report that a leading local firm has received an order from the Japanese Government for several hundred tons of iron, in connection with the naval requirements of that Power in their war with China. It is understood that the order will be followed by others of a still more important character, which will stimulate the local iron trade. Sellers this week, owing to the improved prospects of business, were rather inclined to stiffen prices. Marked bars were quoted £7 10s.; merchant sections, £6 10s.; and common bars, £5 10s. Galvanised corrugated sheets are quoted £9 12s. 6d. to £9 15s. for 24 w.g., f.o.b. Liverpool, and £9 15s. to £9 17s. 6d. delivery London. For hoops the price of £6 7s. 6d. to £6 10s. was, at to-day's—Thursday—Birmingham Exchange, firm, and in view of the increased business which producers of this material are hoping to do with the other side of the Atlantic now that the tariff revision, although not wholly satisfactory, has been brought about, it is quite likely that rates will soon advance. It is estimated that the Americans consume some 40,000 tons of hoops for baling cotton annually, and as the new tariff entirely removes the duty on this iron, makers to-day expressed the hope that they would be able to secure some good American orders. Pig iron is in better inquiry, especially foundry qualities. Staffordshire all-mine hot-blast are quoted 55s. to 57s. 6d.; part-mines, 41s. to 42s. 6d.; and cinder, 38s. 6d. to 40s. Northamptons are 40s. to 41s., and Derbyshires 41s. 6d. to 42s. 6d.

A unique attempt to prevent the closing of the Corngreaves Iron Works of the New British Iron Company is now being made by the employés of that concern. A scheme has been formulated by the men for raising sufficient capital to carry on the works by means of subscriptions from local tradesmen, and the workmen and managers themselves. Something like £100,000 is necessary to purchase the works, and up to Tuesday last the result of the canvass was, it is said, £30,000.

Considerable satisfaction is this week expressed in the Birmingham district at the passing of the American Tariff Bill, although all the relief which had been expected to be granted to the iron and coal trades has not been secured. A number of the Birmingham hardware trades will, however, find material relief. Metallic bedsteads, at present paying a duty of 45 per cent., and of which 240,912 dols. worth were sent from the Birmingham consular district to the United States last year, will get the benefit of a reduction of about 10 per cent. The original revision Bill proposed 30 per cent. on chains, as against 45 per cent. at present charged. It is now expected that something like 35 per cent. has been adopted. Last year's export of chains from this district to the States was between 12,000 dols. and 13,000 dols. Cycles constitute one of the largest departments of local trade with America, and is one of the few items in which the export has been kept up, despite the existing tariff of 45 per cent.

The export of machinery from hereabouts has very much declined in importance, although it still continues to some extent, and this will have the benefit of a reduction from 45 per cent. to 35 per cent. The chief item concerned with it is probably tube-making machinery. Steel tubes constitute an important branch of export, especially for cycle making, and in the last quarter of 1893 27,436 dols. worth were entered in the returns of the Birmingham Consulate under this head. The present duty ranges from 30 to 35 per cent., which the original Bill proposed to reduce 25 per cent., but the probability is that it will be left at about 30 per cent.

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester.*—Much the same unsatisfactory position continues to be reported throughout the iron and coal trades of this district that has prevailed for the last few months, and except perhaps that the settlement of the tariff question in the United States may possibly give some stimulus to trade here, the general outlook remains without improvement. There is a continued absence of buying of any weight going on in the iron trade. The coal trade is only saved from more complete depression than has been known for a considerable time past by the extra demand just now coming forward for the supply of requirements in Scotland, and the engineering industries show no indication whatever of reviving activity. In all departments it is a continued dragging on from hand to mouth, buyers and consumers holding back from entering into transactions beyond what they are absolutely compelled, and the prospects as regards the immediate future are about as discouraging as they well could be.

The Manchester Iron Exchange on Tuesday brought together a moderate attendance, but business was again reported as extremely slow, both in raw and manufactured material. For pig iron prices perhaps showed somewhat more firmness to the extent that makers here and there were not disposed to entertain business at the exceptionally low figures which would recently have been accepted, but it could not be said that any actual advance upon late current quoted rates was obtainable. Lancashire makers are still altogether out of this market, where they have to come into competition with district brands, and such business as they are securing is almost so entirely of a special character with regular customers, where they have exceptionally favourable rates of carriage, or where the prices are governed by other considerations, that anything like definite quotations are scarcely possible, and their list rates of about 39s. and 39s. 6d. for forge, to 42s. for foundry, less 2½, at the works, are simply nominal so far as ordinary business is concerned. If anything, rather more firmness is being shown by makers of district brands in holding to what have been the recent quoted rates, and although 3d. to 6d. under these has been taken within the last week or so, it would have been difficult to place orders for Lincolnshire at under about 38s. for forge to 39s. for foundry, net cash, delivered Manchester. In the best foundry brands of Derbyshire some transactions have been put through at prices equal to 45s., net cash, delivered Manchester; but inferior brands are still obtainable at about 43s. net, delivered here. For outside brands coming into this market prices are firm, at the full quotations ruling last week; good foundry Middlesbrough being scarcely obtainable under 44s. 1d. to 44s. 4d. net cash, delivered Manchester. In Scotch iron it is difficult to get any definite quoted prices, as makers have practically little or nothing to offer, and second-hand holders base their prices according to circumstances; but Eglinton could have been bought at about 46s. 3d. to 46s. 6d. net, prompt cash, delivered at the Lancashire ports.

The position in the manufactured iron trade remains practically unchanged; makers report no improvement in the weight of new business coming forward, and it is exceptional where forges are running more than about four days per week. Quoted prices are about as last given, Lancashire bars remaining at £5 7s. 6d., and North Staffordshire £5 10s.; Lancashire sheets £6 17s. 6d. to £7 2s. 6d.; and Staffordshire £7 2s. 6d. to £7 5s.; Lancashire hoops, £5 17s. 6d. for random and £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

Only a very quiet business continues to be reported in the steel trade, with ordinary foundry hematites scarcely averaging more than 52s. 6d., less 2½, and ordinary basic billets £4 net cash, with steel boiler plates quoted by makers about £6 10s., but readily obtainable from merchants at about £6 7s. 6d. delivered in the Manchester district.

In the metal market there is still only a very moderate business being put through, but the upward movement in raw material gives a firm tone to list rates for all descriptions of manufactured goods.

There was some expectation that the settlement of the wages question in the coal trade might be followed by an improvement in the engineering industries, but any anticipations in this direction have so far proved altogether delusive. Instead of any improvement, the position in the engineering industries has, so far as the employment returns of the trades' union societies are concerned, been steadily growing worse. Last month the Amalgamated Society of Engineers had to report a considerable increase in the number of out-of-work members on their books, and the returns for the present month show a further considerable increase in the same direction, about 1000 additional out-of-work members having come upon the books during the last couple of months, and the returns now show nearly 10 per cent. of the total membership in receipt of out-of-work support. In this immediate district, where some slight improvement was noticeable recently, the position has been getting worse, and there has been a decided increase in the local returns of out-of-work members, which now reach about 9 per cent. of the membership in this immediate district.

The returns as to the condition of trade generally throughout the country also continue very discouraging, and there is no intimation of any prospect of improvement from any of the large engineering centres. In view of this generally depressed condition of trade, the action which has been taken by the men on the North-east Coast, in striking for an advance in wages, is looked upon by the responsible officials of the Society as having been a very ill-advised step, and certainly it has proved a costly one to the Society, as this dispute alone has thrown something like 2000 members on the books for financial support.

In the coal trade the local and inland demand for all descriptions of fuel continues extremely slow, and four days per week represent the full average that the pits are working. The better qualities of round coal meet with only the slowest possible demand for house-fire consumption, whilst the commoner descriptions of round coal continue only in very indifferent request for ironmaking, steam, and general manufacturing purposes. Fairly large orders have, however, been coming into the district for locomotive fuel to meet the requirements of Scotch railway companies who have sent their own wagons to the pits in this district to be loaded up, and this has enabled rather better prices to be got in such cases. Generally, prices for all descriptions of round coal continue very low, with a good deal of cutting and irregularity in the open market. At the pit mouth best Wigan Arley coals only in exceptional cases average more than 11s.; Pemberton 4ft. and seconds Arley, 10s.; common house coals, 8s.; with steam and forge coals, about 7s. to 7s. 6d., something like the last-named figure having been got for locomotive fuel going into Scotland. Engine classes of fuel, although perhaps not quite so great a drug upon the market as they have been recently, are still plentiful and low in price, common slack being readily obtainable at 3s. 9d. to 4s.; medium sorts, 4s. 6d. to 5s., with best qualities quoted at 5s. 6d. to 6s. per ton at the pit mouth.

In the shipping trade a fairly active business is still being done, but this is mostly in connection with supplies which are being shipped to Scotland. No materially better prices are, however, being got, ordinary steam coal not averaging more than 8s. 6d. to 9s., and engine classes of fuel 5s. 3d. to 5s. 9d. per ton, delivered at the ports on the Mersey.

*Barrow.*—The hematite iron trade is still very quiet, and no improvement can be noted during the week. Buyers are only securing small parcels, and those for prompt consumption. From foreign, colonial, and continental sources there is a very poor trade offering. Prices show practically no change on the week. Warrant iron is quoted at 43s. 8d. per ton net cash sellers, and 43s. 7d. buyers, while makers ask 44s. to 45s. 6d. per ton for parcels of mixed Bessemer numbers, net f.o.b. The trade in forge and foundry iron is practically *nil*, and only a limited business is doing in Bessemer qualities.

Stocks of pig iron in warrant stores have been steadily held during the week. Transactions have been few, and only a reduction of 10 tons is notified. There is now in stock 158,323 tons, being an increase of 63,700 tons since the beginning of the current year.

Another furnace has been blown out this week in West Cumberland, and a further one will be stopped in a few days. This is a result of the poor demand for pig iron and the absence of profit to smelters at current prices. There are now thirty-four out of seventy-five furnaces in the district in blast.

Steel makers are still short of orders, and prospects of either stoppage or short time in most of the departments are imminent. There is a fair activity in steel plates for shipbuilding purposes, and the mills are busy on good orders. A fair demand still exists.

Iron ore is quiet in tone at late prices, viz., 8s. 6d. per ton for ordinary qualities.

Shipbuilders and marine engineers are busy, and likely to remain so. Some good repair orders are in hand in addition to the Admiralty and general work, but the inquiry for new tonnage is reported to be very small.

The works recently leased by Messrs. Westray, Copeland, and Co., engineers and ironfounders, at Barrow, have been acquired by Mr. David Caird who has put down a new and valuable plant, and is now commencing business with prospects of a fairly good trade.

Mr. W. B. Peat, of Barrow and Middlesbrough, has been appointed receiver and manager of the Solway Hematite Iron Company, and during the course of the current month will issue a report to the shareholders showing the company's financial position. The closing of these works would be a bad look-out for Maryport.

Shipping is very quiet, and the exports of pig iron and steel during the past week have only totalled up to 10,332 tons, compared with 17,407 tons in the corresponding week of last year, a decrease of 7075 tons. The aggregate shipments of metal this year so far has reached 473,008 tons, against 476,342 tons in the corresponding period of last year, a decrease of 3334 tons. The decrease in steel shipments this year represents 70,786 tons, and the increase in iron shipments 67,452 tons.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

The South Yorkshire collieries have not been so busy during the last ten days. Bank holiday had something to do with this, for although St. Lubbock is not much held in the Barnsley district, its generous recognition elsewhere acts upon the trade. Little demand has been reported for house coal, and the business generally is considerably below the average. The steam collieries, which have been sending a good tonnage to Hull and the other Humber ports, are fairly well employed, the men working on an average five days a week. Other colliers engaged in the getting of household and gas coal are only working three days a week. This being the first week under the new arrangement, it was expected that there would be some dissatisfaction when the miners received their wages with a 10 per cent. reduction. More serious than a little grumbling was experienced. Some few concessions in kinds have been made, but nothing large or general enough to vary quotations materially. Silkstones fetch from 9s. 6d. to 11s. per ton; Barnsley house from 8s. 6d. to 10s. per ton; other qualities from 1s. to 2s. lower. The steam coal trade, as already mentioned, is doing a very good business, the tonnage forwarded to the Humber ports being the principal part of the whole output of this district. Prices are steady, and range from 7s. 9d. to 8s. 6d. for Barnrley hards, other qualities being quoted at from 1s. to 1s. 6d. per ton lower. Gas coal is quiet, and prices are unaltered. Manufacturing fuel is dull supplies being very large, and prices low. Good slacks command from 4s. to 5s. per ton. Smudge, 2s. per ton. Inquiries are better for coke, which can now fetch from 9s. to 11s. per ton.

The official return of trade done with Hull in Yorkshire coal, as issued by the Hull Chamber of Commerce, exhibits a satisfactory state of affairs on the whole. This district appears to be rapidly regaining the business which drifted north during the coal strike, and there is the additionally gratifying symptom of trade tending upwards. The total tonnage forwarded to Hull last month from Yorkshire collieries was 221,200 tons, as compared with 183,864 for the corresponding period of 1893, or an increase of 37,336 tons, or 20 per cent. Last month's supply was the largest individual monthly tonnage sent to Hull this year, the next month being May, when 171,856 tons were forwarded to that port. For the completed seven months of 1894 the supply sent to Hull was 1,146,304 tons, as compared with 923,240 tons for the corresponding period of last year. These figures, however, are not so large as those of the same period in 1892 and 1891, when the tonnage was 1,306,920 and 1,304,672 tons respectively. The export of coal to foreign ports from Hull reached a total last month of 107,064 tons, against 76,032 tons for the corresponding period last month. The heaviest weight was taken by North Russia, 33,451 tons, against 21,410 last year. Sweden and Norway took 33,137 tons; Germany, 16,827 tons; Holland, 6310 tons. For the seven months the largest customer was Sweden and Norway, North Russia and Germany coming next. The number of collieries on the list was 177, Denaby Main being at the top with 36,552 tons, or 16½ per cent. of the whole coal trade of the port. The second place is occupied by Monk Bretton with 9632 tons, then follow Thrybergh Hall and Carlton Main with 9496 and 9296 tons respectively. These four collieries sent 64,976 tons, or 29·27 of the whole trade of the port in Yorkshire.

Our foreign trade in hardware and cutlery during July represents a total value of £143,464, against £175,184 for July of last year. This decrease is largely due to the cause which has been so often mentioned. The falling-off in the United States market is owing to the uncertainty about tariffs, which ought now to be at an end with the acceptance of the Senate Bill. The value sent there last month was only £4907, against £21,502. The other decreasing markets have been Russia, France, Spain and Canaries, Chili, Brazil, Argentine Republic, British Possessions in South Africa, British Possessions in East Indies, Australasia, and British North America. The only increasing markets for the month were thus Sweden and Norway, Germany, Holland, Belgium, and Foreign West Indies. The decline in business with the United States for the seven months ending July 31st is best seen by comparison of the figures with those of the corresponding period of 1893. Up to July 31st last year, hardware and cutlery were sent to the United States to the value of £141,177. Up to July 31st last, the figures were only £59,898. In steel—unwrought—our foreign business amounted last month to £172,159, against £148,343 for July of 1893. This considerable increase is mainly caused by an improvement in Russia, United States, Denmark, and British North America. Russia has advanced from £11,538 to £25,625; Denmark, from £3559 to £9844; France, from £7189 to £10,651; United States, from £28,434 to £35,186; British North America, from £9596 to £13,820. Decreases are shown by Sweden and Norway, Germany, Holland, British East Indies, and Australasia.

It is not expected that the Chinese conflict with Japan will have much effect upon orders for war material for either country. Two battleships are being built for the Japanese Government, one on the Tyne, the other on the Thames. The orders for the armour, as already mentioned in The Engineer, have been secured by Messrs. Cammell and Co., Cyclops Works, and Messrs. Vickers, Sons, and Co., River Don Works, both of Sheffield. Deliveries are spread over a series of years, and so far the Japanese Government have not instructed the work to be expedited. There is no probability that the warships will be ready until long after the dispute is settled, and as the expenditure caused by the war will have exhausted the Japanese exchequer, there will be little desire to still further embarrass their treasury. A statement that both the Chinese and Japanese Governments have representatives in England buying up war material has no confirmation so far as Sheffield is concerned, and that city would be the first place where inquiries would be made.

In the lighter trades an improvement is reported in the saw-making houses. These are mainly from Eastern markets. It is pleasant to note that Burmah, which has been so long depressed owing to internal disturbances, is now becoming a fairly good customer. Some valuable orders for circular saws have been recently received in Sheffield during this month. One of these orders is from Burmah, which includes a number of saws 6ft. in diameter. Other foreign markets are also ordering pretty freely.

In addition to the orders for railway rolling stock mentioned last week, as having been received by Messrs. Craven Brothers, Darnall, for the Metropolitan and South-Eastern Railway Companies, as well as for the Cheshire lines, other companies are in the market with a good deal of work. Amongst these is the Midland, which has been placing considerable requirements for material for railway stock. All the companies have been short of wagons for a long period, owing to the suspension in building operations during the coal strike, and in consequence of the stagnation which followed it.

In our steel houses a very hopeful feeling prevails. It is believed that business is now upon the turn. A rapid development in railway material is certain, and although shipbuilding remains exceptionally quiet, several of our local firms are pretty well employed upon heavy marine castings and forgings. There is a very good demand for the higher grades of tool steel from home, foreign, and colonial markets. The expectation of an abundant harvest has stimulated a demand for knives, steel parts, and sections of agricultural machinery. The season in these goods has been better than for several years. In files one or two firms are busy, but generally the state of trade is better than it was.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

An improved condition of trade is generally reported this week in this district, and the tone of the iron and steel market is decidedly more cheerful than has been known for a long time. A large amount of business has been done in some branches, and at better prices than consumers would recently pay. It is not altogether the passing of the Tariff Bill in America that has brought about this welcome change, for there were some signs of improvement before, and consumers and shippers were showing anxiety to purchase. They have delayed purchasing pig iron for autumn delivery as long as possible in the expectation that the strikes would end and prices collapse, but the negotiations between the employers and the men on strike have so far proved abortive, and the difficulties are apparently as far off settlement as ever. And now it is not likely that if peace were soon restored the expected fall in prices would ensue, because the time has arrived when exporters must make arrangements for autumn deliveries. The market has turned more in favour of the sellers, as the compromise effected in America with respect to the Tariff Bill is making its influence felt here, and the metal trades generally will derive as much benefit as any from the step that has been taken. Makers anticipate that an impulse to business will be given, and are, therefore, not inclined to let their iron go at the prices they have recently been accepting, as orders that have been held back pending the settlement of this question will be distributed without further delay.

Good orders have this week been given out for Cleveland foundry pig iron to be delivered next month and in October, and the price generally taken for f.o.b. deliveries of No. 3 has been 35s. 6d., but that will not be taken now even for prompt delivery, though buyers are offering it freely. Nearly all the producers are at present quoting 35s. 9d., and this figure can be got. As a matter of fact, No. 3 is exceedingly scarce, scarcely a maker has any in stock, and the production this week will be less than usual because the furnaces are, as a rule, working badly, owing to the stoppage of last Saturday. The twenty-four hours' cessation of operations has been very injurious to the quality of the iron made subsequently, and the quantity is lessened. Thus there is less No. 3 made just when a better demand has sprung up for it, and more of the lower qualities which were already practically a drug upon the market. On this account there has not been the advance in the prices of forge qualities of Cleveland pig that has been noticed in connection with foundry qualities, and the former are now relatively the cheaper. Usually grey forge is 1s. cheaper than No. 3, and recently it has been only 6d. cheaper, but to-day there is a difference of 2s., for while one has gone up the other has declined. Grey forge is 33s. 9d., and is weak at that. No. 1 Cleveland pig is at 38s., and No. 4 foundry 34s. 6d. In the warrant market more life has been reported during the last few days, and speculators have been buying freely for a rise in prices, which they think can hardly fail to follow the intelligence from the United States. Cleveland warrants have risen to 35s. 9d. cash. In Connal's public warrant stores, on Wednesday night, 94,525 tons of Cleveland pig iron were held, the decrease this month being 867 tons. In consequence of the scarcity of No. 3 in makers' hands, a considerable quantity is now being withdrawn from the public stores, and that fact will have its effect in strengthening the market. For East Coast hematite pig iron the demand has not yet materially improved, but it must do so soon, because more activity has appeared in the steel plate and angle trades of this district, and the consumption of hematite pig must necessarily increase. The quotation for mixed numbers at present is 43s., and little can be bought below that. Foreign iron ore is plentiful enough, and good Rubio can be bought at 11s. 9d. per ton, delivered at furnaces on Tees-side, the freight from Bilbao being very low, about 4s. 10½d. per ton. Pig iron exports from the Tees are not equal to those of last month, or of the corresponding month last year, but are improving.

On Saturday last, or rather from six a.m. Saturday to six a.m. Sunday, operations at most of the furnaces in Cleveland and South Durham were suspended in order that the men might have their demonstration in favour of an eight hours' day, which they are determined to have. The stoppage, though only for twenty-four hours, has seriously affected the quality of the production ever since, and makers have not been able to get their due proportion of the higher qualities this week, so that their loss is not measured by the reduction in the quantity of iron made on the day of the stoppage alone. The men allowed a few furnaces to be kept in operation, viz., those at Seaton Carew, Carlton, and Ormesby Works, where the eight hours' days has been conceded. The Redcar Works were also kept in operation, the employers paying the men 2s. 6d. extra for the day. A furnace at the Ayrsome Works was also working, as it was running on spiegel, and a stop would have been unfortunate, as operations might not have speedily been resumed, and besides this the expense of the stoppage would have been greater than in other cases. Several thousand blast furnacemen met at Middlesbrough, and with bands playing and flags flying they marched down to Southbank, where they passed a resolution expressing their thanks to those firms who had conceded the eight hours, and their determination to have the three shifts per day at the other works. The masters are willing enough to grant the concession if it would not materially enhance the cost of production. They argue that it will, and the experience of the three firms which have adopted the new system is of too short a duration to settle the matter yet.

Manufacturers of finished iron and steel are in some respects better off than they have been for some time; indeed, the steel plate and angle makers have done so well within the last few days in booking orders that they have raised their quotations 2s. 6d. per ton. They have not got any important order from local consumers, for the strike of moulders still keeps the shipyards stopped, and they do not require plate and angles. However, good contracts have been secured from the Scotch shipbuilders, who cannot buy at home, because the steel works there are closed by the miners' strike, and the consequent scarcity of fuel. Steel ship plates are now at £5, and angles at £4 15s., both less 2½ per cent. and f.o.t. The steel rail trade is extremely dull, and exports of railway material from this district have not for years been so small. The stoppage of the Darlington Works will make no difference, because the competition is chiefly with the Welsh and Sheffield producers. The quotations for heavy steel rails with some firms is as low as £3 10s. net at works.

During the last few days the members of Lloyd's Committee have been paying their annual visits to the iron and steel works, shipyards, and engineering works of this district. The members were Messrs. W. H. Tindall (chairman), S. J. da Coster, T. L. Devitt, J. Glover, B. Martell (chief surveyor), and A. G. Dryhurst (secretary).

No further efforts have been made this week to bring to a termination the strike of moulders, which has lasted now for over five months, and is fearfully hampering the shipbuilding and engineering industries of the district. It is throwing out of employment thousands of other workmen; indeed, the number of men on strike is not a tenth of those who are idle in consequence of it. At some of the marine engine works castings have been obtained from Scotland and even the Continent, and operations with them are being more fully carried on. But the men on strike are doing their best to prevent the masters from obtaining castings from other districts, and by threatening to stop the works of any founder supplying castings to an establishment where the moulders are on strike, they have pretty well succeeded in paralysing their masters' business. The demand for forgings is fairly good. The Darlington Forge Company keeps its establishment in full operation employing over 700 men, and the work it has in hand includes crank shafts for the P. and O. Company, twin-screw brackets and stern frames for the Cunard Company, large castings and forgings for the steering gear of H.M. first-class battleships Majestic and Magnificent, rudder forgings for the White Star Line, heavy stern frames for the North German Lloyd's steamers, &c. It has orders for cast steel wheels for the North-Eastern, Great Eastern, London and South-Western, and various Indian and South American railways.

A large and increasing business is being done by the coalmasters of the North of England, there being considerable activity in the demand for both steam and gas coals, and deliveries of the former are very heavy to continental ports, the importers taking advantage of the low freights that now prevail, but which cannot be expected to last long when the autumn demand fairly sets in. Better prices are being realised for steam coals, and 11s. per ton f.o.b., for best Northumberland is paid. Blast furnace coke is stiff at 12s. 6d. per ton, delivered on Tees-side, or 14s. 6d. f.o.b., and buyers are not backward about giving these figures.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE was a strong impression in trade circles towards the close of last week that the colliers' strike was about to terminate. Now, however, less hope is entertained of an early settlement. The leaders of the miners are divided, and violently oppose each other as to the policy to be adopted, while the employers have not in the least degree retired from their original position of uncompromising opposition to the demand for an advance of 1s. per day in their wages. By a majority of 35 to 31, the miners' delegates have adopted a resolution advising the men to go back to work on an increase of 6d. a day, along with a guarantee from the masters that wages shall not be reduced during the next eighteen months. This proposal is meeting with almost violent opposition from large numbers of the colliers, and there is scarcely any likelihood that the employers would agree to it, even were the miners at one in its favour. The strike has now lasted for nearly two months, and done much to retard business in a great many departments of industry besides the iron and steel trades, which remain practically at a standstill.

The Glasgow pig iron market is inactive. Last week the feeling latterly was that, as the strike was thought to be ending, warrants were a likely investment at current prices, and it was reported that several operators on 'Change were picking up fair lots in anticipation of a rise in price. In the last few days, however, the market has been dull, with warrants comparatively neglected. Scotch warrants have sold from 42s. 2d. to 42s. 3d. cash, and Cleveland at 35s. 9½d. one month. Cumberland hematite has exhibited a little more animation in the last few days, as a result of the American tariff provision for the free admission of iron ore. The expectation is that this enactment will stimulate the import into the United States of hematite ore from Spain, leading to at least a temporary increase in its price. As a consequence, holders of hematite pigs have been firm this week, all the more that there is none of this class of iron being produced at present in Scotland. Business has been done in Cumberland warrants from 43s. 9½d. to 43s. 11½d. cash.

The prices of makers' pig iron are as follow:—G.M.B. f.o.b. at Glasgow No. 1 43s. 6d. per ton; No. 3, 42s.; Monkland No. 1, 46s. 6d.; No. 3, 42s.; Carnbroe No. 1, 48s.; No. 3, 46s.; Clyde No. 1, 55s. 6d.; Gartsherrie No. 3, 52s.; Summerlee Nos. 1, 55s. 6d.; No. 3, 49s. 6d.; Calder No. 1, 56s. 6d.; No. 3, 49s. 6d.; Coltness No. 1, 57s.; No. 3, 52s.; Glengarnock at Ardrossan No. 1, 53s.; No. 3, 48s; Eglinton No. 3, 48s. 6d.; Dalmellington at Ayr No. 1, 50s.; No. 3, 46s.; Shotts at Leith, No. 1, 55s; No. 3, 51s.

There is no change in the number of furnaces in blast, which is seven, compared with 61 at this time last year.

The shipments of pig iron from Scottish ports in the past week amounted to 3853 tons, compared with 5576 in the corresponding week of last year. Of the total Italy took 1200 tons, Canada 120, South America 70, India 25, Australia 50, France 15, Holland 670, Belgium 15, China and Japan 450, other countries 185, the coastwise shipments being 1053, against 1678 tons in the same week of 1893.

Business in malleable iron and steel continues upon a most restricted scale. The works are still closed, and neither buyers nor sellers are in a position to undertake transactions with anything like confidence.

The iron and steel manufactured goods shipped from Glasgow in the past week embraced locomotives worth £2270, sewing machines £4850, other machinery £2622, steel goods £4218, and general iron manufactures £14,700. These figures indicate a slight improvement on the shipments of the last few weeks, but they are still unsatisfactory.

Considerable quantities of coals continue to reach the Clyde from English ports. Hitherto the prices obtained have been but moderate. A tendency now shows itself towards advancing rates, but the demand is small owing to so many of the larger consumers having their works closed.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

APPEARANCES seem to indicate that the steam coal trade has entered upon one of those periodical declines which are inseparable from the history of the trade. At present the drooping tendency is slight, and prices this week are only about 6d. per ton less than last. Still the tendency exists, and I note that on 'Change this week, at Cardiff, the demand was only moderate, and the usual sign of weakness, falling prices for seconds, was noticeable. So far coalowners are not much concerned, and some are inclined to think that the depression may pass off. House coal quotations are maintained. Cardiff quotations this week are as follows:—Best steam coal, 11s. 6d. to 11s. 9d.; seconds, 11s.; dry sorts, 9s. 9d.; common small, 5s. 9d.; best small, 6s. to 6s. 3d.; best Monmouthshire large, 10s. to 10s. 3d.; dry sorts, 9s. 9d.; house coal, best, 11s.; No. 3 Rhondda, 10s. 6d.; brush, 8s. 6d.; small, 6s. 6d.; No. 2 Rhondda, 8s. 9d. to 9s.; through, 7s. to 7s. 3d.; small, 5s. Patent fuel quotations are maintained. Pitwood 15s. 9d. Tendency upwards. At Swansea the shipment of patent fuel last week was 3882 tons, Oran taking 1950 tons. Coal shipments a good average.

Two subjects have been well to the front this week in the district, and all other matters have been dwarfed in comparison. The first is the eight hours' legislation for colliers, and the other the American tariff. With regard to the first, the two colliery representatives in the House are opposed, Mr. D. A. Thomas supporting local option, each district being able to regulate its own arrangements, while Mr. Abraham, "Mabon," supports the hard-and-fast line which I have all along contended in this column would be pernicious to coalowners and to masses of colliers. Mr. Thomas's amendment was carried by a majority of five, and it may fairly be taken as settling the matter. New collieries just opening out may try the plan, as the men have no distance to travel underground, but I believe that if resorted to it would be abandoned, as we have seen in other industries.

Enactments with regard to coal-working have always been framed in a liberal and merciful spirit. At the beginning of the coal era, when the law began to interfere with the liberty of the collier, it swept the women and girls out of the pits; then it protected children, and put its interdict upon the employment of boys under a certain age. Since then its action has always been wise, and with a view to the saving and security of life. The measure now thrown out would have been an exceptional piece of hardship, and the monition not to work more than eight hours daily would in many cases practically be limiting actual labour to six hours daily, to the grave loss of the collier.

The other subject, the tariff, is now regarded in Swansea as safe, and though only a compromise has been effected, and the arrangement probably may not be of long duration, still the feeling on 'Change this week at Swansea, as compared with that of last week, is greatly improved; and if labour troubles can only be allayed, bright times are thoroughly anticipated in the near future. I am glad to hear favourable reports of the proceedings at the great colliery enterprise of the Dowlais Company at Aberdare Junction. The water difficulty, which from the first was regarded as the great obstacle, the place being in the centre of the coalfield, has now been overcome, and sinking is going on rapidly. The shale now also gives well-known indications of approaching coal, and it cannot be long before some veins are touched. At the Ader good work is also being done, and Llanbradach has two pits in active operation.

There was a rumour this week that the Great Western Railway was going to reduce coal rates at Swansea, but I have not seen it substantiated. The wish in this case is evidently father to the rumour. If rates were reduced in the case of iron and steel, there would be a good deal of satisfaction, but it would have to be generally done. Steel bars sent from the principal ironworks have to do with various lines linked with each other. I note also that coal from the Rhondda is often in the same condition. It is sent from the Ocean or the Albion on to the Taff Vale, is shunted on to the Brecon, and again on to the London and North-Western Railway if for Birkenhead, or to the Cambrian if for Aberystwith.

I am glad to note the ability with which the Cambrian Railway is worked, the punctuality of its trains, and the marked conveniences enjoyed by passengers in the holiday season. It must, however, be noted that holiday traffic on local lines will show badly this season, which has been a blending of winter, autumn, and summer.

One of the leading ironmasters has favoured me with his opinion of iron and steel prospects, and I must admit that they are not hopeful. Much depends upon American business for tin-plates. If this should improve, so, too, would the tin-bar trade. As for rails, the outlook is bad. What is wanted, he said, is a greater variety of uses for steel; and, until these are forthcoming, we have nothing else to do than to struggle on.

I am glad to hear that the new industry at Cyfarthfa—the brickworks—have turned out a marked success. There is a large make going on just at present, and a full demand. Ironworks not unfrequently get supplies of bricks from the North of England and from Scotland. As far as Cyfarthfa is concerned the management is independent of outside make. It is to be regretted that there is not an opening for Bessemer slag, the same as for basic. Huge hills are now being reared near the principal ironworks, and any quantity would, practically, be given away. The inventive mind found a rich quarry in the refuse from gasworks and other industries, and here is an opening again which may have profitable issues.

Numerous subsidences of land are occurring in the mineral district, notably in the Aberdare and Merthyr Valleys, in the Rhondda, and near Neath, and I hear that actions of law are likely to test the responsibility of landlords.

The periodic movement of the Cardiff Corporation with regard to a harbour trust is again to the front, and so also is a project for the Corporation acquiring the tramways in the way just effected by Newport. With regard to the former, a majority of the Corporation have supported the Trust. The minority, however, is a formidable one, and the magnitude of the scheme, I expect, too vast to be grappled with, especially if, as some contend, Barry should be included. Cardiff has to complete its huge waterworks, carry out its electric lighting, double its tramways, and other incidental matters first. One of the minority suggested the consequences of a strike as a matter for grave consideration in coming to a settlement of the question. The Newport Corporation have been in communication with the directorate of the Ebbw Vale works respecting the rumoured removal of the works, and pointing out the desirability that Newport should be selected as a site.

The secretary of the works has promised to put the proposition before the directorate, and there, for the time, it ends. I cannot state if there is any ground for the rumoured removal. If too big a scheme, the adoption of the Dowlais tactics in having a modernised branch on the sea-board might be feasible. That is the future of the Welsh works, with one or two exceptions. It is fortunate that ironworks have been of a duplex character, with a coalfield as well as ironworks, and in the case of Tredegar and Rhymney this is turning out well.

Iron and steel are only in small demand. One small parcel of rails has gone to Highbridge, and some moderate consignments of steel bars to the tin-plate works this week. Crop ends continue in demand. Dowlais sent off a quantity last week, and an average make of bars. Cyfarthfa continues busy. Two workmen were prosecuted last week for neglecting work, and fined 10s. each.

Large quantities of Bilbao ore have been coming in this week to the leading works. Latest Swansea quotations, iron and steel, are:—Glasgow pig, 42s. 3d.; Welsh bars, £5; steel rails, heavy, £3 15s. to £4; light, £4 7s. 6d. to £4 10s.; sleepers, angles, channels, &c., according to specification. Steel sheets, £6 to £6 5s.; iron, £5 15s. to £6 10s.; Bessemer steel bars, £4 to £4 2s. 6d.; Siemens best, £4 2s. 6d. to £4 5s. Tin-plates: Bessemer cokes, 10s. 3d. to 10s. 4½d.; Siemens, 10s. 4½d. to 10s. 7½d.; best charcoal, 11s. 6d. to 12s. 6d.; ternes, 28 + 20 c., 19s. to 23s.; wasters, 6d. to 1s. less per box than primes; odd sizes usual extras; all delivered in Prince of Wales Dock, Swansea, cash less 3 and 1 per cent. Block tin is advancing, £68 to £68 5s.

Tin-plate shipments show a little improvement, and better is expected next week. Shipment last week, 54,996 boxes; received from works, 40,955 boxes. Some tin-plate works are again closing, but I expect only temporarily. Coke at Cardiff and Swansea quotations maintained.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE outlook in the iron and steel trades remains very much as reported for some time past. The pig iron business is still rather quiet, and orders are not coming to hand freely from any sources. The different departments of the malleable iron trade are also but insufficiently engaged, buying is still restricted to the smallest possible quantities, and prices continue low, with here and there a tendency to decrease.

From the Silesian district the reports concerning the situation of iron business are not very encouraging, the amount of orders booked being exceedingly small, especially in the crude iron department, and prices are as weak as ever, makers having to give way considerably upon the nominal quoted rates to meet the competition of foreign houses. With regard to the employment in the finished iron and engineering industries, rather more favourable accounts have been coming in. Bars and plates are in fair but not very brisk request, and the wire mills are also in good operation. The prices for most articles of finished iron are pretty firm all round.

Iron business in Austria-Hungary has become rather more quiet upon the week; the demand for both crude and finished iron, though still satisfactory, no longer shows the exceeding briskness that has been noticeable for some time past. For the present the blast-furnace works as well as the rolling-mills report themselves even more than sufficiently employed, and are, therefore, enabled to patiently await the end of the quiet season. Iron export has not very favourably developed this year, because on the Roumanian and Eastern markets the Germans are gaining ground from month to month, offering at very low rates. The railway and engineering department is rather badly off for new work, existing orders as well as those holding out being few and of small weight. In Hungary some orders of importance are expected to be given out soon; only just recently the supply of the iron material for the new electric underground railway at Buda-Pesth has been granted to the Rima-Murany Ironworks.

French trade during June of present year is stated to have been as under:—

| Import. | 1894. Frs. | 1893. Frs. | Difference for 1894. Frs. |
|---|---|---|---|
| Victuals | 96,860,000 | 89,054,000 | + 7,806,000 |
| Raw materials | 176,769,000 | 199,661,000 | − 22,890,000 |
| Manufactured goods | 46,946,000 | 46,875,000 | + 371,000 |
| | 320,575,000 | 335,590,000 | − 14,715,000 |

| Export. | 1894. Frs. | 1893. Frs. | Difference for 1894. Frs. |
|---|---|---|---|
| Victuals | 58,948,000 | 57,460,000 | + 1,488,000 |
| Raw materials | 70,987,000 | 63 796,000 | + 7,191,000 |
| Manufactured goods | 122,352,000 | 147,002,000 | − 24,650,000 |
| Parcels sent by post | 5,040,000 | 4,830,000 | + 210,000 |
| | 257,327,000 | 273,088,000 | 15,761,000 |

Though the tone of the French ironmarket has weakened rather than improved, the tendency of prices has hitherto been stated as pretty firm. Regarding the business transactions during the first two quarters of present year, the total import of pig iron, malleable iron, and steel amounted to 800,012 t., which shows a decrease of 11,738 t., or 12·8 per cent. against the corresponding period last year. Export was 103,354 t., showing an increase of 4916 t., or 5 per cent. against last year. Import in iron ore amounted to 788,726 t., against 723,802 t. in the preceding year; while export in iron ore was 114,582 t., against 147,223 t. for the first two quarters of 1893.

A pretty favourable condition prevails on the French coal market, engine classes of fuel being well and regularly inquired for, so that prices could be firmly maintained. The consumption of pit coal in France is estimated on 34,875,000 t. for 1893, against 36,551,000 t. for the year 1892; France yielded 25,738,000 t., while the rest was imported. Production of coal in 1892 amounted to 26,178,000 t.

Since last week the Belgian iron market has not changed, and decidedly not improved. All departments are reported to be but indifferently engaged, while the competition of the German firms prevents the works from venturing upon the long-intended advance in the quotations for bars and sectional iron.

If changes have taken place on the Rhenish-Westphalian iron market since previous letters, they certainly are too insignificant to be noticed. A firm tendency prevails in the pig iron trade, and demand is fairly good for the present quiet season. Forge pig is specially well inquired for, while the business in spiegeleisen drags on in a lifeless fashion. Since last week, when demand could be stated to have slightly improved, no alteration has taken place on the finished iron market. Bars are tolerably well inquired for, though next to nothing has been done on foreign account for some time past; the few contracts that are booked are for home requirements. Girders have been in regular request, generally, makers complaining of depressed quotations rather than demand. The hoop mills are satisfactorily engaged and likely to continue so for several weeks to come. Regarding the plate and sheet trade, it can only be repeated what has previously been told, and there is little prospect that the unsatisfactory condition of prices so justly complained of will improve in the near future. Wire and wire nails as well as rivets are in rather lively request, but prices remain extremely depressed. The situation of the wagon factories has, on the whole, improved, 3750 load wagons having again been given out by the Government Railway Administration. Prices, of course, are low, having been considerably pressed down by South German competitors, but no foreign offers have been accepted this time.

Supposing that the existing means of conveyance will be insufficient during the time of the Berlin Industrial Exhibition in 1896, the firm of Siemens and Halske have submitted a proposal to the City Magistrate offering to construct an electric railway at their own expense from the centre of the town to the place of exhibition on the Treptow Field. The electric railway is to be of the underground system, similar to that at Buda Pesth, which for more than five years has proved most successful in every respect.

## AMERICAN NOTES.

(*From our own Correspondent.*)

New York, August 9th.

The plethora of money is evidenced this week by the refusal of the banks of this city to accept more money from the interior at any rate of interest because of their inability to lend what funds they have. The steady outflow of gold, now down to nearly 50,000,000 dols., is alarming the business community more than the Washington politicians. Industrial and commercial conditions are improving a little, but the grand break will not occur until the revenue measures under consideration are disposed of. During the past week seventeen rolling mills started up or increased from single to double turn. Six blast furnaces blew in; four rail mills booked orders for 9000 tons standard and girder. Billet mills have more business offered than they see fit to take. Prices are weak in all channels. Railroad traffic shows some little improvement. The coming November elections will sweep one-third of the Democratic representatives from office in the Northern States, and leave the present dominant party forever in the minority.

## LAUNCHES AND TRIAL TRIPS.

On Friday, the 10th inst., the s.s. Beechley left the Tyne on her official trial trip. This vessel was recently launched by Messrs. C. S. Swan and Hunter, Wallsend-on-Tyne, and has been built to the order of the North of Ireland Steamship Co., Mr. W. R. Rea managing owner. She is of the following dimensions: 322ft. by 41ft. by 23ft. 1½in. moulded depth, built on the improved partial awning deck system, cellular double bottom throughout, and all the most modern appliances for the rapid loading and discharging of cargo. Engines, 23in., 37in. and 61in. by 39in. stroke, built by Messrs. Westgarth, English and Co., of Middlesbrough. The vessel will have the highest class at Lloyd's, and has been built under the personal supervision of Mr. Lewis, of Belfast. Mr. Rea and Mr. Lewis both expressed themselves highly satisfied with the results of the trial.

Melton Mowbray Sewage.—A Local Government inquiry was held on Wednesday at the Town Hall, Melton Mowbray, before Colonel J. Ord Hasted, R.E., of the Local Government Board, for permission to borrow £4050 for improvements at the sewage works. Mr. Edmund Jeeves, the Surveyor to the Local Board, explained the scheme, stating that after investigating numerous systems of sewage disposal, the Board had decided to adopt the International system of Ferozone and Polarite as being the most economical and efficient process. The sewage is at present treated by the lime process, which has given rise to serious complaints of pollution and the destruction of fish life. The Board have now determined to abandon the old system of tanks, and to construct others upon the continuous upward flow self-cleansing principle as embodied in the Candy Tank, which has been also adopted by H.M. Government. In addition to the Polarite filters the works will be provided with three clarifiers to economise chemicals and save labour. There was no opposition, and it is intended to carry out the work forthwith.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

1st *August*, 1894.

14,708. Table Cricket Game, C. W. Douglas-Willan and J. Jaques, jun., Bridgend.
14,709. Machines for Boring Articles, A. King and A. C. Oakes, Nottingham.
14,710. Waste Water-closets, J. Day, Wolverhampton.
14,711. Feed-water Purifiers and Heaters, J. Chapman, Swinton.
14,712. Apparatus for Combination with Gas-meters, G. F. Underwood, Kidderminster.
14,713. Antifriction Pulleys, &c., F. Simmons, London.
14,714. Button in Two Parts, W. H. Sladdin, Yorks.
14,715. Traps for Drains, &c., J. Quarnby, Manchester.
14,716. Cycling and Similar Caps, J. Gardner, Manchester.
14,717. Appliances for Controlling or Regulating the Time of Infusion of Tea, J. Crabtree, Lincoln.
14,718. Pneumatic Sole for Boots, J. McKenny and P. Redmond, Dublin.
14,719. Oil Lamp Burners, G. W. Mohrstadt, Birmingham.
14,720 Oil Lamps for Cycles, G. W. Mohrstadt, Birmingham.
14,721. Hair Curling Appliances, J. Walker, Birmingham.
14,722. Smoke Plate, A. Fitton, Manchester.
14,723. Fabric Cutting Machine, F. Wever, Manchester
14 724. Suspending Skirts to Blouses, A. P. Groser, Bristol.
14,725. Knitting Machines, W. I. James and S. Clarke, Stafford.
14,726. Cycle Wheel Construction, T. Cope, Birmingham.
14 727. Surgical Instrument, C. W. Howatson, Perthshire.
14,728. Skate Wheels, F. I. Gibbs and W. Wright, Birmingham.
14,729. Hat Retainer, J. H. Wood, Blackpool.
14,730. Greenhouses, T. Main, Glasgow.
14,731. Driving Gear for Cycles, C. B. Lawson, Glasgow.
14,732. Penstocks and Sluice Valves, M. J. Adams, York.
14,733. Channels for Deodorising Sewage, H. Stoffert, Manchester.
14,734. Pneumatic Tires, P. A. Craven, London.
14,735. Power Looms, J. Angus and W. Aitken, Galashiels.
14,736. Swivel Drawbar for Coupling Wagons, R. J. Stanley, Cardiff.
14,737. Clutch Fastening, G. A. Austin, Bury.
14,738. Boots and Shoes, E. Whatcott and E. Bridgewater, London.
14,739. Longitudinally Folding Bedstead, G. B. Sharpe, Builth, South Wales.
14,740. Ball Bearings, O. Collins, London.
14,741. Maturing Wines, H. A. Leverett and A. Martin, London.
14,742. Folding Box, A. Merritt, C. Batty, and H. C. Brooke, London.
14,743. Photographic Shutters, H. T. de la Crouee, London.
14,744. Drill Stock, G. E. Cornioley and D. Cairns, London.
14,745. Colouring Matters, J. C. L. Durand, D. E. Huguemin, and A. J. J. d Andiran, London.
14,746. Solitaire Stud, A. Walker, London.
14,747. Propulsion of Ambulances, W. and E. Allday, London.
14,748. Lubricators, H. Lucas, London.
14,749. Chain-pulls, The Automatic Chain Company, Ld., and G. H. Gardner, London.
14,750. Bicycles, &c., P. Vincent and A. Vincent, London.
14,751. Attaching Buttons to Garments, G. H. S. Farrant, London.
14,752. Holding Window Sash Cords, L. Robson, London.
14,753. Boxes for the Preservation of Food, W. L. Wise.—(*The Aktieselskabet Carl Lunds Fabriker, Denmark.*)
14,754. Skid for Vehicles, T. Crooke, London.
14,755. Mineral Grate, T. Langer. London.
14,756. Apparatus for Making Studs. C. J. Hewitt Liverpool.
14,757. Goods Showing Appliance, F. A. Wilshere, Manchester.
14,758. Water-colour Paints, G. C. Dymond.—(*The Firm of L. Auerbach and Co. [H. Stoeber's Successors], Germany.*)
14,759. Bottle Stoppers, G. C. Dymond.—(*J. G. Schmidt, Germany.*)
14,760. Treatment of Sewage, H. L. Sulman, London.
14,761. Oxygen Manufacturing Furnace, C. T. Cayley, London.
14,762. Producing Parquetry Surfaces, O. Hocking, London.
14,763. Displaying Placards, E. St. J. Frost and S. Shuttleworth, London.
14,764. Puzzle, J. M. Arnot, London.
14,765. Reproducing Designs, R. Greville-Williams, London.
14,766. Condensers, H. L. Doulton and L. E. Sanceau, London.
14,767. Acid Purification, H. L. Doulton and L. E. Sanceau, London.
14,768. Electric Arc Lamps, A. L. Shepard, London.
14,769. Producing Sulphuric Acid, R. W. Hill, London.
14,770. Producing Sulphuric Acid, R. W. Hill, London.
14,771. Joining Railway Rails, N. Douglas and A. MacDonald, London.
14,772. Block Agglomerated and Briquette Fuels, J. Lyle, London.
14,773. Sausage Stuffers for Meat Chopping Machines, W. von der Nahmer, London.
14,774. Dredging Apparatus, J. C Lang, London.
14,775. Combined Pins, S. W. Pedley, London.
14,776. Lamps, G. C. Dymond.—(*Verbeeck, Briquet, and Co., Belgium.*)

2nd *August*, 1894.

14,777. Comparing Insurance Statistics, W. Schooling, London.
14,778. Tea, Coffee, or other Substance Infuser, W. Pearce, Birmingham.
14,779. Jointing Pipes and Tubes, L. Seager, Sittingbourne.
14,780. Contrivance for Beating-up Eggs, M. S. Wilson, Chippenham.
14.781. Manufacture of Pianofortes, J. and A. Acock, Worcestershire.
14,782. Screw Propellers of Vessels, J. Taylor, Liverpool.
14,783. Bottles, H. Cheesman, Hartlepool.
14,784. Refuse Destructing Furnaces, S. Willoughby, London.
14,785. Trouser Leg Bottom Spring, R. J. Stanley, Cardiff.
14,786. Flushing Syphons, W. Sharp and W. Cruickshanks, Glasgow.
14,787. Cigar and Cigarette Holders, J. W. White, Liverpool.
14,788. Textile Fabrics, J. S. Lenton and R. B. Caldicott, Bradford.
14,789. Tea Cups for Milking Machines, A. Shiels, Glasgow.
14,790. Preventing Scales in Steam Boilers, G. P. Gardner, Glasgow.
14,791 Apparatus for Sifting Cinders, J. Mitchell, Birmingham.
14,792. Saw for Mitre Cutting, &c., E. Pedrazzolli, London.
14,793. Mail Carts, T. Morris, V. Furmidge, J. Morris, and J. Wilkinson, Nottingham.
14,794. Preservation of Ferns, E. W. Hunter, Leeds.
14,795. Cycle Saddles, D. A. Martin, Birmingham.
14,796. Antimaccassar Holder, C. Laight and J. Smith, Redditch.
14,797. Chains for Transmitting Power, W. Andrews and F. Warwick, Birmingham.
14,798. Felloes of Wheels, W. Andrews and F. Warwick, Birmingham
14,799. Golf Irons, Clubs, &c., R. Ramsbottom, Manchester.
14,800. Envelopes for Letters, &c., J. C. Martin, London.
14,801. Raising Lamps, &c., F. W. Vernon and J. Blackham, Birmingham.
14,802. Suspending Swing Seats, &c., R. Hall, Manchester.
14,803. Cycle Lamps, J. Kirk and A. Broadbent, Birmingham.
14 804. Pneumatic Pads for Trusses, T. J. Jackson, Dublin.
14,805. The Gravity Springless Lock, W. S. Brown.—(*G. F. Elsey, Canada.*)
14,806. Receptacle for Coins, &c, A. M. Aspinall, Huddersfield.
14,807. Window Fasteners, R Batey, Halifax.
14,808. Swaging Circular Bodies, G. Hookham, London.
14,809. Tramcar Buffers, J. H Betteley and A. M. Terry, London.
14,810. Sock and Stocking Garter, F. Ballard, London.
14,811. Music Holders, F. D. Cross, London.
14,812. Window-sash Fastener, A. Phelps, Liverpool.
14,813. Appliance for Cleaning Baths, J. Le M. Bishop, Manchester.
14,814. Road Skates, J. S. Cooke, London.
14,815. Liquid Cooling Apparatus, E. Deutsch, Manchester.
14,816. Tables for Invalids, F. J. Moberley, London.
14,817. Dress Hooks and the like, J. Smart, Manchester.
14,818. Apparatus for Loading Coal, E. Jones, Sheffield.
14,819. An Improved Toy, M. W. Lowinsky, London.
14,820. A New Substance for Dyeing Purposes, B. Simpson and Spiller, Ld., and R. J. Friswell, London.
14,821. Treating Fatty Substances, W. O. Robbins, London.
14,822. Inkstands, A. D. Furse, Sunbury-on-Thames.
14,823. Windows, O. Hocking. London.
14,824. Studs, F. Parker, London.
14 825. Hollow Woven Bands, E. Hinnenberg, Germany.
14,826. Bed Rest for Invalids or the like, M. Carver, London.
14,827. Mud Guards for Bicycles, &c., C. W. Price, London.
14,828. Training the Growth of Human Ears, G. Swete, London.
14,829. Steam Engines, H. G. Smith, London.
14 830. Knife and Plate Cleaner, J. F. H. V. Hoop, London.
14,831. Showing Names of Stations, J. S. D. Shanks and T. Harrison, London.
14,832. Machine for Making Butter, A. Daul, London.
14,833. Fluid-pressure Engines, S. Robinson, London.
14.834. Bottles, H. A. Hayden and B. T. Kearns, Wolverhampton.
14,835. Florentine Sun-blinds and Fittings, A. Darling, London.
14,836. Sliding Windows of Railway Carriages, R. Pearce and J. C. Taite, London.
14,837. Dress Guards, A. Vorwerk, Germany.
14,838. Cloth Suspenders, A Steinman, Germany.
14,839. Fixing Hooks to Ladies' Dresses, F. Nüsken, Germany.
14,840. Valve Gear of Engines, J. R. Hopper, London.
14,841. Diaphragm for Phonographs, W. E. Hunnex, Croydon.
14,842. Treating Sugar Cane Juice, H. H. Leigh.—(*G. Cambray, France.*)
14,843. Draught Preventer for Doors, W. H. Thrift, London.
14,844. Securing Metallic Clamps, M. Schubert, London.
14,845. Mechanical Milking Apparatus, C. G. P. de Laval, London
14,846. Manufacture of Cement from Schist, L. Mack, London.
14,847. Storing Electric Energy, J. E. Liardet, London.
14,848. Ladies' Companion or Case, T. L. Jones, London.
14,849. Collapsible Boxes, A. R. Carter and J. P. Robertson, London.
14,850 Filaments for Electric Lamps, R. Langhans, London.
14,851. Retaining Head Coverings, R. H. Wall, London.
14,852. Decorating Earthenware, &c., J. T. Newell, London.
14,853. Assisting Cyclists to Ride, C. H. Guest, London.
14,854. Pneumatic Tires, C. H. Guest, London.
14,855. Pipe Benders, T. Seaton, sen., and J. T. Fraser, London.
14,856. Exacting Sulphur from Raw Pyrites, A. Buisine, London.
14,857. Bedsteads, A. W. Darré, London.
14,858. Purification of Saccharine Juices, J. Y. Johnson.—(*E. Javaux, C. F. Gallois, and F. Dupont, France.*)
14,859. Distribution of Electricity, W. G. and C. W. Little, London.
14,860. Automatic Check Registers, W. Gedge, London.
14,861. Life-buoy and Float, G. V. Fosbery, London.
14,862. Dancing Liquid, R. Biewend, London.
14,863. Propelling Vehicles, J. Gordon and H. Gordon, London.
14,864. Bottle and Pipe Cleansing, M. Pollak, Germany.
14,865. Furnace, M. Pollak, Germany.

3rd *August*, 1894.

14,866. Latch for Setting-on Rods, &c., J. Garside, Dukinfield.
14,867. Unbreakable Ventilating Door, E. Williams, Castleford.
14,868. Removing Sludge from Tanks, F. P. Candy, London.
14,869. Ventilating Gusset for Drawers, &c., A. Ash, Manchester.
14,870. Straight-bore Tobacco Pipes, J. W. Priestley, Lightcliffe.
14,871. Saddle-pins for Bicycles, &c., G. J. Bowcock, Southport.
14,872. Venetian Blinds, W. H. Wilson, Liverpool.
14,873. Impregnating Textile Fabrics, J. Smith, Liverpool.
14,874. Heating Boiler Feed-water, G. Sinclair, Glasgow.
14,875. Transfers for Pottery Ware, J. C. Bailey, Longport.
14,876. Braking Spindles, W. Fisher and W. Duckworth, Halifax.
14,877. Sash Fasteners for Windows, J. L. Travis, Halifax.
14,878. Edge-setter Machines, R. W. and L. Bateman, Halifax.
14 879. Service Flushing Cisterns, A. Taylor, Glasgow.
14.880. Machines for Cleaning Metal, G. Ashford, Newport, Mon.
14,881. Double Seal Scour-out Closet, T. Biggs, Waterford.
14,882. Beehives G. Castleden, Framlingham.
14,883. Drying or Steaming Machines, J. Smith, Liverpool.
14,884. Means for Fastening Boots, A. H. Bancroft, Church.
14 885. Carburetting Water-gas, W. A. Fourness, Manchester.
14,886. Pneumatic Tires, W. Bowden, Manchester.
14,887. Railway Chair and Sleeper, A. E. Muirhead, Glasgow.
14,888. Screw Tap, Collar, Cap, and Wrench, T. G. Blood, Birmingham.
14,889. Science Lanterns, J. H. Barton, Manchester.
14 890. Consuming Smoke and Saving Fuel, G. Stirk, Bradford.
14,891. Spanners, T. C. Maddock, Birmingham.
14.892. Jointing Pipes, J. Dakers and J. Swinburne, Bristol.
14,893. Curtain Ring, H. C. Davidson, Wrotham.
14,894. Soda Crystals, C. P., J., and H. Peak, and A. G. Haddock, Wigan.
14,895. Pocket Protector, H. Bird and F. T. White, Birmingham.
14,896. Fire-escapes, J. H. Meyer, Saltaire.
14,897. Pressing Felt Hats, J. and J. W. Rowley, Manchester.
14,898. Toy Target, M. Sugar.—(*D. Nagg, Belgium.*)
14,899. Gum Pots and other Vessels, J. Edges, London.
14,900. Cycles, C. Byrne, London.
14,901. Boots and Shoes, J. W. Jones and G. Phillips, London.
14,902. Hooks for Dress, E. S. Green, London.
14,903. Treating the Fibres of Flax, T. Burrows, London.
14,904. Heating Apparatus, W. and I. Darby and R. U. Evens, London.
14,905. Neutral Sodium Carbonate, E. Dresel and J. Lenhoff, London.
14,906. Sand-paper Carrying Rolls, A. Pochin, F. H. Pochin, and H. Addison, London.
14.907. Device for Catching Dripping, M C. Lincoffs, London.
14,908. Rudders, H. Lumley, London.
14,909. Cycles, J. Hancock, London.
14,910. Regulating Centrifugal Fans, G. M. Capell, Stony Stratford.
14,911. Locks, G. Mason, London.
14,912. Wire Drawing, C. Berkenhoff, Germany.
14,913. Locking Device for Hooks, H. Amberg, London.
14,914. The "Unique," J. J. Wilson, London.
14,915. Pneumatic Tires, R Waugh, London.
14,916. Sanitary Pipe, P. Stiens. London.
14,917. Joint for Connecting Pipes, A. and F. G. Johnson, London.
14,918. Rendering Proteine Soluble, L. Prochazka, London.
14,919. Mashing and Brewing Process, L. Prochazka, London.
14,920. Turning the Circumference of Belt Pulleys, A. Knöpfel, London.
14,921. Notation of Music, W. Cooper, London.
14,922. Electrically Regulating Signals, W. Fiedler, London.
14,923. Recovering Spirit from Varnishes, A. Gray, London.
14,924. Oil Lamps, W. Perkins, London.
14,925. Pneumatic Wheels and Tires, J. W. Barclay, London.
14,926. Electric Telegraph and Signal, F. Hollins, London.
14,927 Process of Treating Town Refuse, C. Jones, London.
14,928. Apparatus for use in Harmonic Analysis, G. U. Yule, London.
14,929. Cup Handle, C. Asprey and G. E. Asprey, London.
14,930. Hat and Cloak Supports, H. P. Hoghton, Manchester.
14,931. Manufacture of Stockings, H. C. Schott, London.
14.932. Mechanical Toy, H. C. Schott, London.
14,933. Applying Paints to Glass, W. R. McKay and R. S. Moseley, London.
14,934. Artificial Stone, A. Muirhead and G. Hackford, London.
14,935. Construction of Saucepans, M. G. Roberts, London.
14,936. Funnels for Casks, G. Waterfield, London.
14,937. Method of Night Signalling, J. A. Cox, London.
14,938. Ornamentation of Porcelain, W. Grûne, sen., London.
14,939. Protecting Watches, G. J. and C. H. Kirby, London.
14,940. Rotary Engines, M. E. P. Chaboche, London.
14,941. Producing Designs upon Wood by Charring, A. Guattari, H. H. Prall, and G. L. S. Maggiolini, London.
14,942. Protecting Live Steam Pipes, W. Elbers, London.
14,943. Velocipedes, H. Beyer, London.
14,944. Carrying Cycle Accessories, G. E Osmond, London.

4th *August*, 1894.

14,945. Latch Runner for Umbrellas, H. R. Foley, Birmingham.
14 946. Soap, &c, S. Rosenblum and F. L. Bartélt, Keynsham, near Bristol.
14,947. Cork-drawing Machine, W. Ashton, Southport.
14,948. Travellers' Skip, F. Pearson, jun, Nottingham.
14,949. Easel Mount, A. W. Adams and G. Houghton, Reading.
14 950. Wicker Basket with Wood Partitions, W. H. Wyatt, Bristol.
14,951. Rear-driven Safety Bicycles, T. Knowles, Manchester.
14,952. Revolving Receptacles for Waste Water, T. Knowles, Manchester.
14,953. Pneumatic Tires, C. Woolley, London.
14,954. Apparatus for Obtaining Cyanides, J. S. M. Arthur, Glasgow.
14,955. Rocking Chairs, W. S. McLennan and T. Morton, Glasgow.
14,956. Cycle Lamps, J. Parker, T. Sanders, and J. B. Worton, Birmingham.
14,957. Portable Structures, R. F. Hall, Birmingham.
14,958. Combination Cycle Tool, O. Ward and E. Eite, Birmingham.
14,959. Cycle and other Bells, J. Harrison, Birmingham.
14,960. Butt and Hinge for Doors, &c, W. Griffith, Croydon.
14,961. Brace, T. W. Hill, London.
14,962. Cyclists' Rifle Carrier, T. Whitehead, Wolverhampton.
14,963. Coiled Draw Springs for Harness, W. Mills, Sheffield.
14,964. Cycle Handle, T. Deane and J. Winfield, London.
14,965. Covering of Tramcars, T. Staines and J. Leadbeater, Leeds.
14,966. Tools for Burnishing the Heels of Boots, J. G. Grimsley, Leicester.
14,967. Apparatus for Lighting Sewer, &c., Gases, C. Horton, Birmingham.
14,968. Steering Lock for Safety Bicycles, R. W. Smith, Birmingham.
14,969 Steering Lock for Safety Bicycles, R. W. Smith, Birmingham.

14,970. Manufacture of Piled Carpets, A. Webb, G. M. Whittall, and F. B. Fawcett, Kidderminster.

14,971. Multiplying Ruler, P. Folacci and M. Paviot, London.

14,972. Centrifugal Governors, W. Ashton, Manchester.

14,973. Machines for Cleaning Fibrous Materials, W. S. Archer, Manchester.

14,974. Shuttles for Small-ware Looms, H. Cooper, Manchester.

14,975. Can for Oils, C. C. de Waterford.—(*L. Bettenat, France.*)

14 976. Ball Bearings of Wheels, F. J. Lynam, Ireland.

14,977. Cycle Saddles, J. M. Starley and W. S arley, London.

14,978. Manufacture of Stockings, T. and J. Jones, and H. and A. Langdale, London.

14,979. Wax-thread Sewing Machines, F. W. Farr, London.

14,980. Apparatus for Sifting Cinders, &c , J. Squire, London.

14,981. Picks, W. H. Radford, London.

14,982. Dust-proof Bearings for Cycles, W. H Smith and J. W. Hill, Birmingham.

14,983. Colouring Matters, J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran, London

14 984. Hot-water Doll, G. L. Wilson, London.

14 985. Treatment of Bicarbonate of Soda, W. L. Wise.—(*Solvay and Co., Belgium* )

14 986. Bleaching Powder, W. L. Wise.—(*E. Solvay, Belgium.*)

14,987. Separation of Caustic Alkalies, W. L. Wise. —(*Solvay and Co., Belgium* )

14 988. Electrolytic Table, W. L. Wise.—(*E. Solvay, Belgium* )

14,989. Triggerless Small-arms Lock, G. H Beaumont, London.

14 990. Manufacture of Brushes, H. F. Reinhold, London.

14 991. Heating Calendar Rolls, H. H. Greenhill, London.

14,992. Rake Holders, A. J. Boult.—(*O. Ehlig, Germany.*)

14,993. Scoops for Groceries, A. J. Boult.—(*B. R. Eichler, Germany* )

14,994. Inkstands, A. J. Boult —(*M. Wiener, Apolda.*)

14 995. Apparatus for Obtaining Gas, P. Dvorkovitz, London.

14,996. Pedal Attachment for Cycles, R. L. Jenks, London.

14 997. Preserving Matrices, C. A. Allison.—(*J. A. Whitney, United States* )

14,998. Ornamental Coverings for Floors, W. W. Wagner, London.

14,999. Pneumatic Tires, H C. Webb, London.

15 000. Driving Electric Machinery, H. Soifranc, London.

15,001. Elastic Tires for Cycles, A. Fendt and A. Uzel, jun., London.

15,002. Lighting Miners' Lamps, W. Ackroyd and W. Best, London.

15,003. Attaching Buttons to Wearing Apparel, H. Fletcher, London.

15,004. Telephonic Installation, G. Ritter, London.

15 005. Adjusting Pulleys, B. Rosenfeld and H. Tschichholz, London.

15,006. Cooking and Roasting Ovens, F. Heinemann, London.

15,007 Type-writing Machines, H. G. Ashley and C. C. Leathers, London.

15 008. Steam Boilers, J. Moore and T. Spencer, London.

15 009. Artificial Legs, W. R. Honsuc'e, London.

15 010. Collar and Shirt Studs, C. H. Collins Birmingham.

15,011. Making Coal Vases, C. Stroud, Wolverhampton.

15,012. Blowing Apparatus, I. Kiralfy.—(*M. Ruble, United States.*)

15 013. Manufacture of Barrels, &c , C. E. Bratt, London.

*7th August*, 1894.

15,014. Vermin Trap, T. W. Moore, London.

15,015. Cycle Saddles, A. G. Brookes.—(*G. O. Draper, United States* )

15,016. Gas-heated Hand Iron, C. Kirby and J. G Liversidge, Leeds.

15,017. Steaming Textile Fabrics, T. Illingworth, Bradford.

15,018. Stoppers for Bottles or Jars, J. V. Clarke, Manchester.

15.019. Bottles, W. Breffit, Castleford.

15,020. Spray, D. Sinclair, Watford.

15,021. Window Conservatories, J. Tonry, Wolverhampton.

15,022. Production of Engraved Rollers, J. P. Hewitt, Stoke-on-Trent.

15,023. Self-acting Railway Signals, W. T. C. Pratt, Newport, Mon.

15,024. Gardening Forks, &c , J. W. Yates, Birmingham.

15,025. Attaching Scales to Knife Hafts, S. G. Richardson, Sheffield.

15.026. Coupling Railway Vehicles, T. Cheetham, Manchester.

15 027. Vacuum Controlling Apparatus, A. Shiels, Glasgow.

15,028. Belting, C. Kertland, Glasgow.

15.029. Advertising, A Standring, Manchester.

15,030. Brake Apparatus, P. Weir, Bristol.

15,031. Mounting Photographic Prints, H. Walker, Altrincham.

15,032. Combination Bottle Stopper, &c , W. Pearce, Birmingham.

15,033. Tires for Cycles, J. Tullo, Glasgow.

15,034. Measuring Electric Currents, W. Thomson, Glasgow.

15,035. Extension Cranks for Cycles, P. C. Noble, Grantham.

15,036. Cycles, F. M. Ketton, Nottingham.

15,037. Knitted Fabrics, R. Hutchinson and J. A. Wilson, Nottingham.

15,038. Attaching Handles to Cutlery, W. Bamford, Rochdale.

15,039. Water Tap, R. Aisbett, jun , and W. Wood, Sunderland.

15,040. Top Lug and Stem for Cycles, G. J Bowcock, Southport.

15,041. Producing Designs on China, Sir H. Doulton and J Slater, Longport.

15,042. Roundabouts, T. Clayton, Manchester.

15,043. Automatic Check Till, T. H. Wem, Birmingham.

15,044. Cradles, Cots, &c., G. Riley, Swinton, near Manchester.

15,045. Life-saving Grating, W. H. Hewett, Kingston-on-Thames.

15,046. Water-tube Boiler, T. Sumner, Liverpool.

15,047. Tie or Scarf Grip, J. Reid, Millom.

15,048. Fog Signals for Railways, R. Gascoigne, Worksop.

15,049. Railway Construction, F. Pfeiffer and C. Lier, Berlin.

15,050. Photographic Dark Slides, W. D. Pepper, Glasgow.

15,051. Laying Electric Cables, R. Middlemass, Scarborough.

15,052. Ticket Pocket, K. Leverkus, Leipsic-Gohlis, Germany.

15,053. Continuous Clockwork Alarum, F. Harrison, Houghton-le-Spring.

15,054. Toy, E. Lycett, Birmingham.

15,055. Fastener for Window Sashes, L. Turnock, Stockport.

15,056. Ropes or Cables, E. S. Bond and G. H. Cooper, Birmingham.

15,057. Fish-hooks, B. S. Martin, London.

15.058. Manufacture of Wire Ropes, W. B. Brown, Liverpool.

15,059. Distributing Soap, G. C. Dymond. —(*W. Wilclow, United States.*)

15,060. Furnaces, G. C. Dymond. —(*A. Albeser, Germany.*)

15,061. Hydraulic Engines, J. E. Schumacher, T. E. Pickering, A. Whittam, and S. C. Platts, London.

15,062. Boring Bit, D. Honeywood and E. L. Austin, London.

15,063. Gas Bracket Lamp-cock, T. Handel, Ilminster.

15,064. Colouring Matters, J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran, London.

15 065. Electrical Contact Apparatus, E. Tyer, London.

15,066. Making Variegated Candles, &c , J. David, London.

15,067. Making Acids, O. Imray. —(*The Farbwerke vormals Meister, Lucius, and Bruning, Germany* )

15,068. Fire-escape, A. Thamm, London.

15,069. Lowering Apparatus, A. H. G. Thamm and J. Leers, London.

15,070. Overhead Electric Conductor, W. J. B ewer, London.

15,071. Steam Boiler and other Furnaces, O. D. Orvis, London.

15,072. Submarine Signalling System, L. J. Blake, London.

15,073. Flower-bolting Reels, H. H. Lake.—(*S D. Barr, United States.*)

15,074. Nut with Cap or Capsule for Bolts, G. Bähr, London.

15.075. Governor for Steam Engines, L. H. Rutherford, London.

15,076. Feed Apparatus for Boilers, F. M. Sandillon, London.

15,077. Valve Mechanism for Engines, G. I. Rockwood, London.

15,078. Cycle Driving Gear, W. and E. Allday, London.

15,079. Invisible Stand for Photographs, S. W. Allen, London.

15,080. Combination of Pencils, C. H. Dumenil and W. H. Brigg, London.

15,081. Lamp Reflectors, E. Tilmann and C. K. Lexow, London.

15,082. Magneto-electric Machines for Cycles, E. Tilmann and C. K. Lexow, London.

15,083. Pneumatic Tires, W. and E. Allday, London.

15 084. Safety Belt for Bathing, H. Prague Bauer, London.

15,085. Yarn Washing and Scouring, J. Tattersall, London.

15,086. Oil Refining, B. J. B. Mills.—(*J. H. and C. H. Campbell, United States.*)

15,087. Controlling Motive Force, H. E. Newton.—(*C. C. Worthington, United States* )

15 088. Letter and other Envelopes, E. Lacôte, London.

15,089. Manufacture of Floor Cloths, A. Hagele London.

15 090. Reciprocating Mechanism, J. G. Lorrain —(*Z. G. Sholes, United States* )

15,091. Indicating Speeds of Shafts, A E. Edwards —(*Count Lippe's Administration Lindenhof, Germany.*)

15,092. Votes Counting Book, W. Watkins, Dorchester.

15 093. Coupling Railway Brakes, S. W. Carlton, London

15 094. Closed Arrangement for Gates, A. Helwig, London.

15,095 Composition for Paving Stones, C. Jost London.

15,093. Stoves for Heating Air, M. Jaeniigen London.

15,097. Winding and Gassing Yarns, H. B. Arundel, Manchester.

15 098. Apparatus for Mounting Diamonds, A. F. Richter, London.

15 099. Automatic Loom Stop Motions, H. Carnier, London.

15 100. Apparatus for Dealing Cards, W. Gedge, London.

15.101. Sowing or Distributing Grain, L. Doneuville, London.

15,102. Chimney Cowls, R. Haddan.—(*P. Perinnon, France* )

15,103. Skate Blades, T. W. Bryant London

15 104. Pulverisers, T. Parker, J. D. Wright, F. F. Stuart, and A. M Colquhoun, London.

15,105. Ink-wells, S H. Boyden and Messrs Cooper Denison, and Walkden, Ld., London.

15,103. Newspaper and other Files, A. P. Fggis, London.

15.107. Oil Heating and Vaporising, W. H. Pearson, jun., London.

15,108 Gun Locks, F. de W. Granger, London.

15,109. Gas Motors, G Schimming, London.

15,110. Stopping and Starting Vehicles, H. Goodwin, London.

15,111. Millinery Trimmings, S. Symons, London.

*8th August*, 1894.

15 112. Cake Baker, J. S. Marshall, London.

15 113. Brace or Suspender Button-hole, A. Breeze, London.

15 114. Spike Ball Puzzle, J. Hazel, London.

5 115. Tricycle, G. Whyte, Guernsey

15,116 Regulating the Action of Pistons, S. Wright, Monmouth

15 117. Velocipede Cranks, A. C. Davison and H. Lucas, London.

15,118. Locking Window Fasteners, R. Cough, London.

15,119. Making Tea and other Infusions, F. T. Bond, London.

15,120. Propelling and Steering Ships, T. Dargue, Glasgow.

15,121. Brushes, J. H. Godman, St. Albans

15,122. Marine Engines, G. W. Clark, Birmingham.

15,123. Chimney-pot and Ventilator, W. Peyton, Halifax.

15,124. Semi-collapsible Pontoon, J. B. Murray and J. P. Turnbull, Glasgow.

15,125. Apparatus for Fare-checking, A. L. Taylor, Liverpool

15,126. Fire-escape, R. H. Johnson, Derby.

15,127. Steam Engine, G. A. Newall, Bristol.

15,128. Flying Apparatus, P. E. Lautenschläger, Manchester.

15,129. Evacuating Lamp Bulbs, A. Malignani, Manchester.

15,130. Shield for Vaccination Spots, M. J. Phillips, Manchester.

15,131. Fittings for Baths, J. and L. W. Shepherd, Davenport.

15,132. Filters, R. Gringan and D. C. Smith, Glasgow.

15,133. Collapsible Crates for Cycles, E. Poizot, Liverpool.

15,134. Locking Stop-rod, W. Whitehead, T. Greaves, J. Dalton, and S. Greaves, Manchester.

15,135. Umbrellas, F. A. Wilshere, Manchester.

15,136. Hat Sweat Bands, L. Marshall, Manchester.

15,137. Advertising, T. A. Allen, London.

15,138. Working Swing Boats, W. Cartwright, London.

15,139. Shuttles, W. Schalck, Germany.

15,140. Deoxidising Textile Fibres, A. Gruschwitz, London.

15,141. Means for Holding Lamps, O. Krumbholtz, London.

15,142. Driving of Pulsometer Pumps, R. Sepp, London.

15,143. The Safety Tissue, V. Jetley and G. Jetley, London.

15,144. Construction of Indian Clubs, H. A. Newth, London.

15,145. Cab Lamp Signal, R. Macdonald, London.

15,146. Lubricating Machinery, C. H. Berry and J. Snowdon, jun., London.

15,147. Incandescent Gas Burners, R. Goehde, London.

15.148. Controlling Liquids, W. C. L. van Schaik, London.

15,149. Windows, L. Robson, London.

15,150. Gas Producers, B. Dawson, London.

15,151. Corset Fastening, W. T. Low and E. D. Hoyland, London.

15,152. Locomotors, C. A. Faure, London.

15,153. Ships' Course Indicating Lamp, N. L. Jacobsen, London.

15,154. Cinder Sifter, E. Geisenberger, London.

15 155. Heating System, A. J. Boult.—(*J. Sander and J. Kühne, Germany* )

15,156. Construction of Fire-proof Floors, J. Roy, Liverpool.

15.157. Musical Toys, A. R. Breial, London.

15,158. Repair of Stockings, A J. Boult.—(*C. Gunst, Germany.*)

15,159. Bicycles, Tricycles, &c., H. Claughton, Liverpool.

15.160. Walking Sticks, A. J. Boult.—(*A. Fiquet, France.*)

15,161. Bust Supporters, H. Schindler, London.

15,162. Removing Creases from Garments, E. M. Molyneux, Liverpool.

15,163. Washing Machines, A. J. Boult —(*W. Schubert and H. Hiltner, Germany* )

15,164. Cash Registering Appliances, C. S. Snell, Cornwall.

15,165. Spark Extinguishing Apparatus, G. Sommersberger, London.

15,166. Treating Eggs, J. Swan, London.

15,167. Detachable Protector for Pneumatic Tires, J. H. A. and E. T. Woods and W. T. Henley's Telegraph Works Company, London.

15,168. Preserving Extracts from Lemons, B. Biggs, London.

15.169. Puncture-closing Device for Pneumatic Tires, G. E. Osmond, London.

15.170. Arc Lamps, J. J. Rathbone and A. Chester London.

15,171. Manufacture of Scent Essence, P. P. Monnet London.

15 172. Inflatable Tires for Wheels, A. Pulbrook, London

15,173. Actuating the Notes of Pianos, H. H. Piffard and R. H. Bishop, London.

15,174. Electrical Rolling Contact-making Device, K. Ast, London.

15,175. Roofing Tiles, M. Bohn, London.

15,176 Ventilating Boots, E. Bills, London

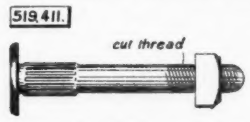
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**519,411.** Bolt, *W. C. North and S W. Sessions, Cleveland, Ohio.—Filed March 4th*, 18·2.

*Claim* —A bolt comprising a head and shank having screw threads cut on the end opposite the head, a portion of the remainder of the shank constructed with longitudinal ribs located a short distance from the head, and formed by the displacement of a portion of the stock constituting the shank, leaving a space between the head and ribs of less diameter than the latter, substantially as described.

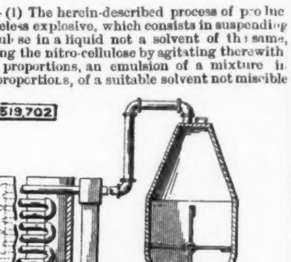
519,411.



**519,702.** Manufacture of Smokeless Powder, *F. G. Du Pont, Wilmington, Del.—Filed August 5th*, 1893.

*Claim.*—(1) The herein-described process of producing smokeless explosive, which consists in suspending nitro-cellulose in a liquid not a solvent of the same, granulating the nitro-cellulose by agitating therewith in proper proportions, an emulsion of a mixture in suitable proportions, of a suitable solvent not miscible to any great extent in the liquid used to suspend the nitro-cellulose and a volatile oil, with a liquid calculated to aid emulsion in proper proportions, hardening and rounding the grains by rotation in an atmosphere of steam, and removing the excess of solvent and the oil by distillation, substantially as described.

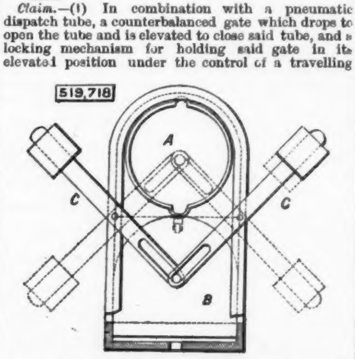
519,702



**519,718.** Gate for Pneumatic Dispatch Tubes, *S. F. Leake, Philadelphia, Pa.—Filed March 1st*, 1893.

*Claim.*—(1) In combination with a pneumatic dispatch tube, a counterbalanced gate which drops to open the tube and is elevated to close said tube, and a locking mechanism for holding said gate in its elevated position under the control of a travelling carrier for releasing said locking mechanism, substantially as set forth. (2) In combination with tube A, the end or outside guide frame $a$, gate B having pivoted counterbalancing levers C, locking pawl $d$, lever $d^2$, link $d'$ connecting said pawl and lever, and actuating mechanism for lever $d^2$ extending into the tube A and operated by a travelling carrier, substantially as set forth.

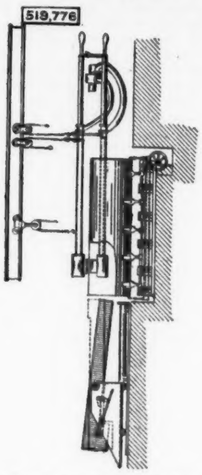
519,718



**519,776.** Welding Apparatus, *C. L. Rowland, Brooklyn, N.Y.—Filed December 22nd*, 1893.

*Claim.*—(1) The combination, substantially as set forth, of a non-travelling cradle having adjustable device for supporting the cylinder to be welded with the seam in the proper plane, facing furnaces movable along the seam, and a horizontally movable anvil also movable along and beneath the seam. (2) The combination, substantially as set forth, of the non-travelling cylinder-supporting cradle, the longitudinally movable facing furnaces, the longitudinally moving anvil, a way or track upon which it moves, and means for moving the anvil uniformly and gradually forward as the work proceeds. (3) In a cylinder welding apparatus, the combination, substantially as set forth, of a pair of horizontally movable over-balanced facing furnaces, their adjustable frame bars supported intermediate their ends, and adjustable connections between the frame bars independent of the frame bar supports and located at one side thereof, whereby the furnaces may be adjusted and locked in fixed relation to each other and to the seam of the cylinder lying between then.

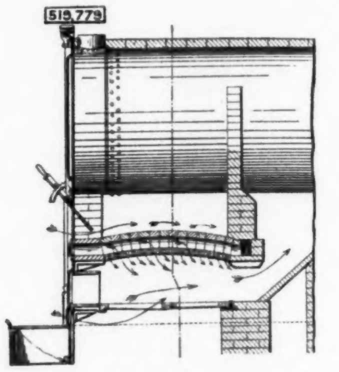
519,776



**510,779.** Smoke-consuming Furnace, *J. M. Thomas, St. Louis, Mo —Filed February 14th*, 1894.

*Claim.*—A steam boiler furnace having an arched down-draught fuel grate of refractory material, supported by the walls of the furnace independently of intermediate support and composed of bars arched longitudinally of the furnace.

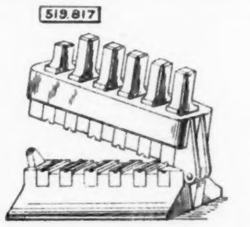
519,779



**519,817.** Swage, *C A. Mette, Santa Cruz, Cal.—Filed October 28th*, 1893.

*Claim* —In a device of the class described, the combination of a base provided with spaced sockets, stationary dies provided with depending tangs engaging said sockets, and lateral shoulders engaging the surface of the base, bracing blocks interposed between said dies a guiding arm hinged to the base and provided with spaced guides and interposed depending bracing blocks, movable dies fitted in said guides and provided with stops, and a finger carried by the base to engage a pocket in the guiding arm, substantially as specified.

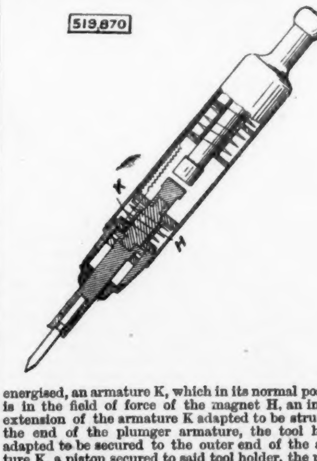
519,817



**519,870.** Magnetic Engine for Reciprocating Tools, *H. S. McKay, Boston, Mass.—Filed July 5th*, 1892.

*Claim.*—In an electro-magnetic engine for reciprocating tools, the combination with two or more magnets or solenoids, a plunger armature adapted to be reciprocated by the same, a magnet or solenoid H situated beyond the other magnets and connected with said magnets in series and so as to be always energised, an armature K, which in its normal position is in the field of force of the magnet H, an inward extension of the armature K adapted to be struck by the end of the plumger armature, the tool holder adapted to be secured to the outer end of the armature K, a piston secured to said tool holder, the piston cylinder, and a pneumatic cushion or spring for said piston and holder, all as and for the purposes set forth.

519,870



# NOTES ON THE STRENGTH OF FRAMED STRUCTURES AS AFFECTED BY ELASTICITY.

By C. F. Findlay, M.A., M. Inst. C.E.

(*Continued from page* 118.)

(7) When M has been determined by means of equations (II.) and (III.), the secondary stress $t$ is obtained from it by the relation $t = \frac{M}{I} r$, where $r$ is the distance from the axis of figure of the link to the extreme edge at which the stress is $t$. When the cross-section is symmetrical $r = \frac{d}{2}$, $d$ being the width of the link in the plane of flexure. This shows the important influence that $d$ has upon the secondary stress. If, for example, in any frame, the depth of each member be doubled, the cross-sectional areas, &c., remaining unaltered, I will be increased in a nearly constant ratio for all the links—about four times—and equations (II.) and (III.) show that M will be increased in the same ratio as I. $\frac{M}{I}$ remains constant, but since $t = \frac{M}{I} r$, $t$ will be doubled. If one link alone be increased in depth, the others being unchanged, the bending moment in all the links united with that one, as well as in the altered link itself, will be increased, and, in a smaller degree, the moments in other links which do not intersect the altered one will also be increased. We thus see that, as far as secondary stress alone is concerned, it is an advantage to make all tension members as narrow as possible in the plane of flexure, and not to give a greater depth to compression members than their length as columns really requires.

This is the advantage gained by the use of eyebars. It is not true, although it has often been said, that the use of eyebars does away with secondary stress, because with the scantlings commonly used for them, the secondary stress in riveted flat bars of the same dimensions would be no greater than the friction of the pins actually used may cause. The advantage of the eyebar, as regards secondary stress, is that it enables bars of small width and considerable thickness to be used, which it would be difficult to unite by rivets, so as to maintain the full strength of the bar. With such bars, whether the joints be hinged or not, the secondary stress is so small as to be negligible. With the wide bars so commonly used in England, this is by no means the case. This point being important, let us illustrate it by considering the simple case of the truss, shown in Fig. 4, uniformly loaded. Suppose the tie-rod in the first instance to be a flat bar, 4in. by ¾in., with a primary stress of five tons per square inch. Let the tension bar C D have also a stress of five tons, and the rafter A C 2·5 tons per square inch. Our object being only to show the effect of varying the section of the tie-rod, suppose the joints at A and B to be hinged, in order to simplify the calculation. For A D, $l$ = 124in., and I. = 4 in inch units. By equation (I.)

$$E \times \theta_{12} = (-2{\cdot}5 - 5) \cot 30 \text{ deg.} + (-2{\cdot}5 - 5) \cot 45 \text{ deg.} = -7{\cdot}5\,(\sqrt{3} + 1) = -20{\cdot}5.$$

By symmetry there is no secondary stress in 2 with a symmetrical load, and therefore equation (II.) gives

$$6 \times -20{\cdot}5 = -\frac{124}{4} \times 2\,M_D^1.$$

$$\text{Therefore, } M_D^1 = \frac{123}{62} = 2 \text{ inch-tons,}$$

Since $r = 2$ and $I = 4$, $t = \frac{M r}{I} = \frac{2 \times 2}{4} = 1$ ton per square inch.

Suppose now that instead of a bar 4in. × ¾in. we use a bar 8in. × ⅜in. in order more conveniently to make a riveted joint, I becomes 16 and $M_D^1$ becomes $\frac{123}{15{\cdot}5}$ or 8 inch-tons. Since in this case $r = 4$ and $I = 16$, we have $t = \frac{8}{16} = 2$ tons per square inch.

(8) If, instead of a simple succession of triangles, we have to deal with such a case as that shown in Fig. 5, or with a lattice girder, it may be shown that the bending moments in the booms will be very much the same as for a simple triangulated girder of the same depth and section. For the web members the case is different. The angles between the vertical posts and the boom will undergo the same deformations as for the simple girder if, as may be assumed, the stresses per square inch are the same in both cases. If the web members are not connected to each other where they intersect, the compression links, such as the post A B in Fig. 5, will require the same width as for the simple girder, and the secondary stresses will be unaltered. If the verticals and diagonals in Fig. 5 are connected at their intersection, $l$ in equation (II.) will be reduced by one-half, and this will cause M to be largely increased. The general conclusion, then, is that if the web members are not connected together at their intersections, the secondary stresses in them will be much the same as in the simple girder, with bracing at the same angles; if they are connected at their intersections, the width of the links must be reduced in the same proportion as their free length, if the secondary stress is not to be increased. This reduction of width would be a perfectly legitimate proceeding from all points of view. The post A B in Fig. 5, if it be riveted to the diagonal tension bar at C, is, as a column, of half the length it would have without that connection, and therefore it only requires to have, in the plane of the figure, half the width and half the radius of gyration it required for the length A B, while its cross-section must be the same in area. Probably the most severely strained from secondary stress of all girders are the lattice girders, sometimes built, of small depth, and with wide lattice bars firmly riveted to each other at every intersection.

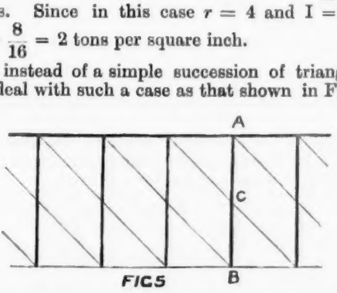


FIG. 5

(9) The idea might suggest itself that secondary stress could be compensated by purposely making the primary stresses excentric to the axes of the links, shifting one of the links at any joint to a definite distance from the intersection of the others, so that the primary stress would produce a bending moment equal and opposite to that of the secondary stress. This would be quite impracticable, even in theory. The only method of avoiding secondary stress would be by introducing initial deformations in constructing the frame, and therefore initial secondary stresses, opposite to those which the load will bring into play. This would present no difficulty to the template maker, but would considerably perplex the erector of bridges. It would mean that the lengths of all the members should be taken from the unstrained diagram of the bridge and the angles between them from a diagram of deformation, or, which is the same thing, that the angles should be taken from the ordinary working drawings, and all the lengths of the various members increased or diminished by quantities equal and *opposite* to the primary strain produced in them by the loads. Considerable force would be necessary then to make the members take the curvature necessary to fit them to their places. An arrangement requiring such delicacy of adjustment could never be carried out successfully in practice. Taking from Table II. the largest of the values of E $\theta$ (which is + 14·9 for the angle between 4 and 16), we see that $\theta$ will be rarely so large as $\frac{15}{12{,}000}$ or ·0012 in circular measure. This angle has an arc of only ·03in. at a radius of 25in., from which it is seen that errors of workmanship may easily produce stresses of similar magnitude to the secondary stresses arising from the loads.

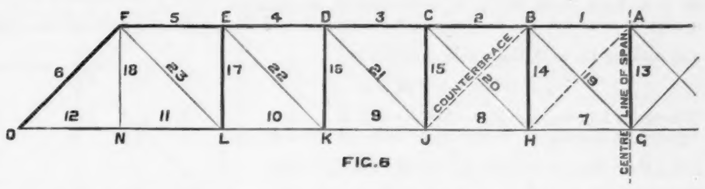

FIG. 6

(10) With regard to the struts, for which it is found that the secondary stress is most serious, it is to be observed that the secondary stress is entirely independent of those considerations which lead to the usual formulæ for the working stress in columns.' These formulæ are empirical, and most of the published experiments on columns are not of a nature to enable deductions to be made from them as to the behaviour of columns within the elastic limit. Whatever be the theory or practice adopted, however, the flexure from deformation of the frame, and the consequent secondary stress must be regarded as superadded to the flexure and stress, arising from other causes, and not as one of the elements allowed for in the column formulæ.

We will now proceed to show how equation (II.) may be made use of for numerical determinations of approximate correctness. If the coefficient $\frac{l}{I}$ be calculated for all the members of a girder, it will be found to be very large for all the members of the web—and where eye-bars are used for the lower boom also—compared to its value for the upper boom. The value of $\frac{l}{I}$ for some of the members of the web will usually be much larger than for others, while still small compared to its value for the upper boom. In those links for which $\frac{l}{I}$ is large, it follows that, other things being equal, M is small. For a first approximation, then, *in determining the values of* M *for the upper boom*, we may neglect altogether the resistance to flexure of many of the web members, and for others we may neglect the resistance at the lower end, since in equation (II.) the coefficient of $M_B^2$ is only half of that of $M_O^2$. With these simplifications the values of M for different points in the upper boom can be determined from equation (II.) with small labour. If the lower boom be of such construction that it is desirable to determine the secondary stresses in it also, a similar method may be applied to it separately. Having, then, the values of M for both booms we can determine them for any web member we may choose by applying equation (II.) to the angles which that member makes with the two booms. If it is desired to go to a second approximation, we should have to go through the booms again, using the values already determined for M in the web members, where in the first approximation M was neglected. It will generally be found, however, that the first approximation is sufficient for practical purposes. The method will be more clearly understood by applying it to one or two cases, and we have chosen for that purpose two railway bridges of about the same span—150ft.—characteristic respectively of American and English practice, and taken at random from published drawings. The loads from which the primary stresses are calculated are the maximum loads the bridges are designed to carry. In the English bridge the equivalent distributed load is:—

| | | |
|---|---|---|
| Dead ... ... ... ... ... ... ... | 1·13 | tons per foot. |
| Live ... ... ... ... ... ... ... ... | 1·39 | „ |
| Total ... ... ... ... ... ... ... | 2·52 | „ |

In the American bridge it is:—

| | | |
|---|---|---|
| Dead ... ... ... ... ... ... ... | ·65 | tons per foot. |
| Live ... ... ... ... ... ... ... ... | 1·42 | „ |
| Total ... ... ... ... ... ... ... | 2·07 | „ |

Take, first, the case of the English design, which is represented in the diagram in Fig. 6.

The necessary data for the calculations are given in the second and third columns of Table I. The third and fourth columns contain the results of a first and second approximation to the values of M in the various members. The fourth and fifth columns contain the values of $r$ and I, which are necessary to deduce from M the values of the stress; and the last column contains the values of the secondary stress for one end of each member at which it is largest.

Table I.

* Of the two values of M at opposite ends of each member, the larger only is given in the table. Where the cross section is symmetrical the sign of M is immaterial. In the upper boom, which is of inverted-trough section, the stresses resulting from M are different at the upper and lower edges, and both are given in the last column.

The deformations of the various angles are given in Table II., in which the values of E $\theta$ have been calculated according to equation (I.), and in which E is in tons per square inch and $\theta$ in circular measure.

Table II.

In the first place let us neglect all values of $\frac{l}{I}$ greater than 2 in calculating M for the booms. This cuts out all the web members except the three tension bars, 21, 22, and 23, and one post 17. Further, in calculating M for the upper boom, assume that, in the four web members retained, M is zero at the lower end of them. Similarly when calculating M for the lower boom, assume that M vanishes at the upper end of the web members. Applying equation II. to the angle between 1 and 13, $44{\cdot}4 = 0{\cdot}09\,(2\,M_A - M_B^1)$, since by symmetry $M_A^{13}$ and $M_G^{13}$ are zero. Also $M_B^1 + M_B^2 = 0$, and therefore $M_A^1 = 247 - \frac{1}{2} M_B^2$.

The similar equation for 1 and 2 at B is

$$76{\cdot}2 = 0{\cdot}09\,(2\,\overset{2}{M}_B - \overset{2}{M}_C - 2\,\overset{1}{M}_B + \overset{1}{M}_A.)$$

Whence, substituting for $\overset{1}{M}_A$ and $\overset{1}{M}_B$ from above we have

$$\overset{2}{M}_B = 171 - \tfrac{2}{7}\,\overset{3}{M}_C.$$

In a similar way we get $\overset{3}{M}_C = 148 + 0{\cdot}27\,\overset{3}{M}_D$.

At D we have $\overset{3}{M}_D + \overset{4}{M}_D + \overset{21}{M}_D = 0$ where $\overset{21}{M}_D$ is given by applying equation II. to the angle between 3 and 21, and making $\overset{21}{M}_J = 0$, the result of which is

$$\overset{21}{M}_D = -\,18{\cdot}5 + 0{\cdot}06\,\overset{3}{M}_D.$$

Whence it follows that $\overset{3}{M}_D = 17{\cdot}4 - 0{\cdot}94\,\overset{4}{M}_D$.

Applying equation II. to the angle between 3 and 4, and using the values of $\overset{3}{M}_C$ and $\overset{4}{M}_D$ already found, we get

$$\overset{4}{M}_D = 134 + 0{\cdot}3\,\overset{4}{M}_E.$$

Proceeding in this way we obtain the value of M at each joint in the boom in terms of its value at the next joint to the left, and eventually we find

$$\overset{6}{M}_F = -\,3{\cdot}3 + {\cdot}43\,\overset{6}{M}_O.$$

Starting again for the lower boom at the joint G, and proceeding from joint to joint, we obtain eventually

$$\overset{12}{M}_N = 37 + 0{\cdot}28\,\overset{12}{M}_O.$$

For the angle between 6 and 12, equation II. gives

$$27{\cdot}6 = 0{\cdot}36\,(2\,\overset{12}{M}_O - \overset{12}{M}_N) - 0{\cdot}52\,(2\,\overset{6}{M}_O - \overset{6}{M}_F),$$

where $\overset{6}{M}_O + \overset{12}{M}_O = 0$, and $\overset{6}{M}_F$ and $\overset{12}{M}_N$ are given above in terms of $\overset{6}{M}_O$. Making these substitutions we find $-\,\overset{6}{M}_O = \overset{12}{M}_O = 3$[illegible] Knowing $\overset{6}{M}_D$ and $\overset{12}{M}_O$, the preceding equations determine the values of M at all the joints in the boom successively.

For the web members the values of M can easily be found when those of the boom members have been determined.

Take the tension bar 22 for example :—

Equation II. applied to the angle between 4 and 22 gives—

$$40{\cdot}8 = 0{\cdot}11\,(-\,100 - 119) - 0{\cdot}96\,(2\,\overset{22}{M}_E - \overset{22}{M}_K),$$

whence $2\,\overset{22}{M}_E - \overset{22}{M}_K = -\,67{\cdot}6$.

Similarly the angle between 10 and 22 gives

$$2\,\overset{22}{M}_K - \overset{22}{M}_E = -\,23{\cdot}0,$$

from which $\overset{22}{M}_E = -\,52{\cdot}7$ and $\overset{22}{M}_K = -\,37{\cdot}9$.

The analysis has here been carried out for the purpose of illustration with a minuteness which would be unnecessary in practice. For instance, the values of M at A and G will not be altered appreciably by supposing the joints at E and L, and all others to the left of them, to be hinged. According to the equations on the previous page, we find that $\overset{1}{M}_A = 179{\cdot}4 - 0{\cdot}001\,\overset{4}{M}_E$, and therefore $\overset{4}{M}_E$ can be neglected in determining $\overset{1}{M}_A$. $\overset{1}{M}_A$ being known, the other values follow in succession.

In general it will not be necessary to proceed to a second approximation; but it is a simple matter to do so if desired. We merely repeat the calculation of M for the joints of the booms, using the numerical values already found for M for the web members in those cases where M had hitherto been neglected. Then, having thus found corrected values for M at all points of the booms, we can recalculate it for the web members. For instance, on the first approximation, in applying equation II. to the angle between 3 and 21, we considered $\overset{21}{M}_J$ as zero. We write it $-\,18{\cdot}6$ when proceeding to a second approximation. Also, at the joint D, instead of

$$\overset{3}{M}_D + \overset{4}{M}_D + \overset{21}{M}_D = 0, \text{ we have}$$

$$\overset{3}{M}_D + \overset{4}{M}_D + \overset{21}{M}_D - 28{\cdot}6 = 0.$$

In Table I. the complete results of a second approximation are given, and it is seen that in all the cases where the secondary stress is considerable the first approximation gave very good results. We have confirmed the validity of the method by working out the results for a small struss rigorously, and comparing them with those given by approximation.

Tables III. and IV. give the data and results for the American bridge represented in Fig. 7.

TABLE III.

| No. of member in Fig. 7. | Primary stress in tons per square inch. | $\frac{l}{I}$ in inch units. | M in inch-tons. 1st approximation. | M in inch-tons. 2nd approximation. | $r$ in inches. | I in (sq. in.)$^2$ | Secondary stress in tons per sq. in. (from 2nd approximation). |

| 13 | +4·2 | 13·5 | 1·3 | 1·3 | 2·5 | 29 | ±0·11 |

The bridge is pin connected, but the bending moments have been calculated on the assumption that all the joints were rigid. It may be seen by examining the results that the friction of the pins would probably be sufficient to prevent any rotation at the joints. For instance, take the joint O at the bearing. The strut 4 has a primary stress of 86 tons. M = 5·5 at O, and the radius of the pin is $2\frac{17}{32}$in. Therefore the coefficient of friction necessary to prevent rotation is $\frac{5{\cdot}5}{86 \times 2\frac{17}{32}}$, or $\frac{1}{23}$. With the post 10 the total stress is 21·8 tons, M = 24, and the radius is $2\frac{7}{32}$ in. Coefficient of friction necessary to prevent rotation $= \frac{21{\cdot}8}{24 \times 2\frac{7}{32}} = 0{\cdot}4$.

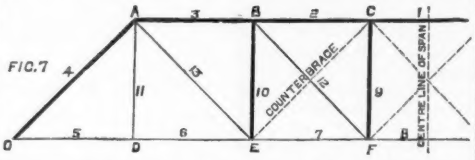

FIG. 7

Considering that the pins are usually a driving fit, the coefficient may easily be higher than this.

As was said previously, the eye-bars in this bridge are of such scantlings that equation II. does not apply, and in practice it would be unnecessary to calculate the secondary stress in them.

TABLE IV.

| Joint of boom. | Angle between | E θ | Angular deformation of boom × E. | Joint of boom. | Angle between | E θ | Angular deformation of boom × E. |
|---|---|---|---|---|---|---|---|
| C | 1 and 9 | + 4·6 | +13·5 | F | 8 and 9 | + 6·6 | −15·4 |
|  | 9 ,, 2 | + 6·9 |  |  | 9 ,, 12 | − 2·9 |  |

| O | 4 ,, 5 | + 7·8 | + 7·8 |  |  |  |  |

Table III. has been calculated by applying equation II. throughout, but the values it gives for M in the eye-bars must be considerably in excess of the real values.

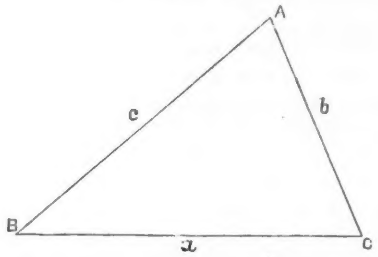
The results tabulated for these two bridges may be studied with some advantage, since the bridges in question are typical of their kind. We have no desire to enter into any comparison of the merits of these types of designs in any other respect than that which we are now discussing. We are fully aware that secondary stress is only one consideration of many that have to be regarded in choosing a type of girder, and we have refrained from giving such references as would identify the bridges we have used for our illustrations, lest it should seem that we wished to suggest such comparisons.

## APPENDIX.

(i.) *To find the change in any angle of a triangle caused by given small changes in the sides.*

The angle A is given in terms of the sides by the equation:

$$2\,b\,c \cos A = b^2 + c^2 - a^2.$$



If A become A + Δ A owing to changes in $a$, $b$, and $c$ amounting to $\delta a$, $\delta b$, and $\delta c$ respectively, we have, by the principles of the differential calculus,

$$-b\,c \sin A \times \Delta A + \cos A\,(b\,\delta c + c\,\delta b) = b\,\delta b + c\,\delta c - a\,\delta a,$$

$$\text{or}\quad b\,c \sin A \times \Delta A = a\,\delta a - a \cos C\,\delta b - a \cos B\,\delta c$$

$$= (b\,\delta a - a\,\delta b) \cos C + (c\,\delta a - a\,\delta c) \cos B,$$

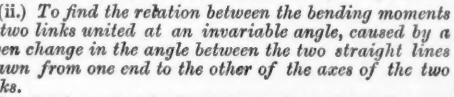
$$\text{whence } \Delta A = \left(\frac{\delta a}{a} - \frac{\delta b}{b}\right) \cot C + \left(\frac{\delta a}{a} - \frac{\delta c}{c}\right) \cot B.$$

When $\delta a$ is due to a stress $t_a$, $\frac{\delta a}{a} = \frac{t_a}{E}$, &c.

Therefore, $E \times \Delta A = (t_a - t_b) \cot C + (t_a - t_c) \cot B$.

(ii.) *To find the relation between the bending moments in two links united at an invariable angle, caused by a given change in the angle between the two straight lines drawn from one end to the other of the axes of the two links.*

Let O A be a straight line joining the ends of the axis of any link, O and A being the points at which it is intersected by the axes of other links forming part of the same frame. Any external forces acting on the link are supposed to be applied at O and A. All the forces acting on the link must be equivalent to two equal and opposite forces P, except in the special case where they are reducible to two equal and opposite couples, a case which we need not consider. Let $p_1$ and $p_2$ be the perpendicular distances from the line of action of P, of O and A. $P p_1$ and $P p_2$ are the bending moments at the ends of the link, which we will call $M_1$ and $M_2$. As drawn in the figure $M_1$ and $M_2$ are both positive, as also are the angles $a_1$ and $a_2$ made with O A by the tangents to the axis in O and A.



Take O as origin and O A as axis of $x$ in employing Cartesian co-ordinates. The moment of P about any point $x$, $y$, on the axis is

$$P \times \left\{p_1 - (p_1 + p_2)\,\frac{x}{l} - y\right\}$$

Therefore, the static equation of equilibrium is

$$\frac{E\,I}{P} \cdot \frac{d^2 y}{d\,x^2} = -\,p_1 + (p_1 + p_2)\,\frac{x}{l} + y.$$

Supposing P—as in the figure—to be positive, and writing $k^2$ for $\frac{P}{E\,I}$, the solution of this equation, subject to the conditions that $y = o$ when $x = o$ and when $x = l$, is:

$$y = p_1 - (p_1 + p_2)\,\frac{x}{l} + \frac{p_2 + p_1\,e^{-kl}}{e^{kl} - e^{-kl}}\,e^{kx} - \frac{p_2 + p_1\,e^{kl}}{e^{kl} - e^{-kl}}\,e^{-kx}\,;$$

When $x = o$ $\frac{d\,y}{d\,x} = a_1$. Therefore,

$$a_1 = -\,\frac{p_1 + p_2}{l} + \frac{k\,\{2\,p_2 + p_1\,(e^{kl} + e^{-kl})\}}{e^{kl} - e^{-kl}}$$

Now, $k^2\,l^2 = \frac{t}{E} \times \left(\frac{l}{\rho}\right)^2$, where $t$ is the primary stress per square inch, and $\rho$ the radius of gyration of the cross section. Whenever the link is of sufficient width to make the secondary stress considerable $k\,l$ will be small enough that $e^{kl}$ and $e^{-kl}$ can be expanded in powers of $k\,l$ and the higher powers neglected. If this be done,

$$e^{kl} + e^{-kl} = 2\left(1 + \frac{k^2\,l^2}{2}\right) \text{ and } e^{kl} - e^{-kl} = 2\,k\,l\left(1 + \frac{k^2\,l^2}{6}\right)$$

Therefore, the above expression becomes:

$$a_1 = -\,\frac{p_1 + p_2}{l} + \frac{1}{l}\left\{p_2 + p_1\left(1 + \frac{k^2\,l^2}{2}\right)\right\}\left(1 - \frac{k^2\,l^2}{6}\right)$$

$$= -\,\frac{p_1 + p_2}{l} + \frac{p_1 + p_2}{l} + \frac{k^2\,l\,(2\,p_1 - p_2)}{6},$$

$$\text{or}\qquad a_1 = \frac{l\,(2\,M_1 - M_2)}{6\,E\,I}.$$

When $x = l_1$ $\frac{d\,y}{d\,x} = a_2$. Therefore,

$$a_2 = -\,\frac{p_1 + p_2}{l} + \frac{k\,\{2\,p_1 + p_2\,(e^{kl} + e^{-kl})\}}{e^{kl} + e^{-kl}}$$

This is the same as the value of $a_1$ with $p_2$ and $p_1$ exchanged each for the other. Therefore,

$$a_2 = \frac{l\,(2\,M_2 - M_1)}{6\,E\,I}$$

If P be negative or the primary stress in the link compressive, the solution of the differential equation is:

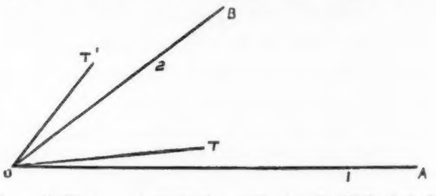
$$y = p_1 - (p_1 + p_2)\,\frac{x}{l} + p_2\,\frac{\sin k\,x}{\sin k\,l} - p_1\,\frac{\sin k\,(l - x)}{\sin k\,l},$$

where in this case $k^2 = -\,\frac{P}{E\,I}$.

Differentiating and expanding in powers of $k\,l$ as before, we obtain exactly the same results.

It is to be observed that these values of $a_1$ and $a_2$ are the same as would have been obtained by neglecting the flexure as affecting the moment at various points in the link, *i.e.*, by putting $y = o$ in the differential equation, but we have preferred the more rigorous method in order to exhibit the degree of accuracy of the results.

If, now, O and B be the ends of the axis of another link united at an invariable angle to the link O A, let these links be distinguished by the letters 1 and 2.



According to what has just been proved,

$$a_1 = \frac{l_1}{6\,E\,I_1}\left(2\,\overset{1}{M}_O - \overset{1}{M}_A\right),$$

where $a_1 = A\,\hat{O}\,T$, O T being the tangent to the axis of the link 1 in O.

$$\text{Similarly,}\quad a_2 = \frac{l_2}{6\,E\,I_2}\left(2\,\overset{2}{M}_O - \overset{2}{M}_B\right),$$

where $a_2 = B\,\hat{O}\,T'$.

Now, $a_1 - a_2 = A\,\hat{O}\,B - T\,\hat{O}\,T' = \theta_{12}$, where $\theta_{12}$ is the change that would occur in the angle between 1 and 2 were there no resistance to deformation at the joint.

Therefore,

$$6\,E \times \theta_{12} = \frac{l_1}{I_1}\left(2\,\overset{1}{M}_O - \overset{1}{M}_A\right) - \frac{l_2}{I_2}\left(2\,\overset{2}{M}_O - \overset{2}{M}_B\right)$$

(*To be continued.*)

---

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Staff Engineers: James Shirwell, to the Terror, additional; Richard Harris, to the Shannon; J. Fielder, to the Victory, additional, for the Pallas. Chief Engineers: George G. Goodwin, to the Bellona; William J. Anstey, to the Pembroke, additional; John Kerr, to the Calypso; Wm. J. Mabb, to the Barrosa; Allan V. Blake, to the Iron Duke; Allan H. Slade, to the Penelope. Engineers: Samuel Godbeer, to the Pembroke, additional; Charles E. Eldred, to the Terror, additional; A. R. Pattison, to the Royal Sovereign; F. W. Highton, to the Wildfire; F. M. Cottam, to the Alarm; Charles J. James, to the Havock; George Ramsay, to the Blanche; Henry E. Tregenna, to the Bellona; W. A. P. Smith, to the Barrosa; Colin M'K. Norris, to the Niger. Probationary Assistant Engineer: H. R. S. Hughes, to the Trafalgar.

## THE IRON AND STEEL INSTITUTE BRUSSELS MEETING.

The autumn meeting of the Iron and Steel Institute was commenced on Tuesday morning at Brussels, under the presidency of Mr. E. Windsor Richards, supported by a large number of past presidents and other members of the Council, and about 400 members, including, besides those from this country, a considerable contingent of German, American, and other foreign members. The proceedings were inaugurated with a reception on Monday evening held by the Communal Council in the Town Hall, where the visitors were received by the Burgomaster and his colleagues; and the formal business began at 10 a.m. on Tuesday, when the President, Council, and members were received by Professor Gillow, the President, M. Briart, the Vice-President, and other members of the local reception committee, in a short but very appropriate speech, which was acknowledged by the President with equal felicity or brevity, so that very little time was lost in compliments.

After the treasurer had given notice of an alteration in the bye-laws to be proposed at the next annual general meeting, to allow members to compound for their subscriptions, and pay a single payment of thirty guineas, the reading of papers was commenced by Professor Gillow, who gave a short sketch of the recent developments in the manufacture of iron and steel in Belgium, dwelling more particularly on the changes wrought by the Thomas and Gilchrist process, illustrating the various points by a well-selected series of statistical data. This occupied only a few minutes, as on account of the paper not being in the hands of the members, it was read from a manuscript in French, no discussion or inquiry being possible. He was followed by M. A. Briant, the president of the Society of Engineers in the Province of Hainault, who may, without dispute, be said to stand at the head of the mining engineers of the country, who read a paper

### "On the Mining Industry of Belgium."

This was an admirable sketch, dealing with all the points of interest in the working of coal in Belgium, where the difficulties are perhaps greater than in any other country, on account of the great amount of disturbance to which the strata have been subjected, and the obstacles to be encountered in sinking through the water bearing dead measures, on the eastern portions of the coalfield where the axes are most developed. These circumstances have led to the necessity of working seams as little as 10½in. thick, while the thickest do not exceed 5¼ft. From the engineer's point of view the most interesting of these details are those connected with the methods of sinking through the cretaceous and Wealden strata, the arrangements for obtaining an adequate output from a deep pit without unduly increasing the speed of winding, and the deep-lift underground pumping engines. Of these parts we give an abstract.

"*Sinking shafts.*—In new winnings great difficulties are sometimes encountered. These include (1) the large amount of water; (2) the loose nature of the rocks. When there is simply much water, while the rock stands well, work can be carried on in the usual manner, by removing the water; it is only a question of unwatering, sometimes difficult, it is true, and always costly, but in itself offering nothing absolutely impossible. Nevertheless, economy in this case causes us to turn to the methods in which the shaft is left full of water. When, however, quicksand is encountered in addition to water, the direct method is no longer possible, and recourse must be had to other processes. Of these the principal ones are the Kind-Chaudron method, long since known in Belgium, and the Poetsch process, which has only recently been introduced. The author shortly described the recent application of both these methods to especially difficult cases.

*Shaft at Ghlin in the Nord du Flénu collieries.*—The following is a section of the strata that had to be passed through:—

| | Metres. |
|---|---|
| Quaternary and Tertiary: sandy clay, sands and gravels | 18·00 |
| Mons limestone, firm ... ... ... ... ... ... ... ... | 6·00 |
| Chalk, white and grey, more or less compact, flint, green sands and blue clay of the upper chalk ... ... | 268·50 |
| Quicksands and gravels with clay intercalated, especially near the bottom... ... ... ... ... ... ... ... | 14·50 |
| Total ... ... ... ... ... ... ... ... ... ... ... ... | 307·00 |

This statement shows how difficult it is to get through the overburden, especially near the bottom. It may be mentioned that the natural water level is 0·50 metres below the surface. The bottom of the tubbing has to bear a pressure of more than thirty atmospheres. Never before had such conditions been experienced, and the problem was the more difficult to cope with as the conditions were altogether unexpected. It was thought that the coal measures would be met with sooner, as they were believed to have been reached at a depth of 292 metres, whence the boring tools had brought up the *débris* of black and grey clay, shale, and fragments of coal resembling cannel. This was only the Wealden clay and lignite (*Aachénien* of Dumont), which was immediately followed by the bed of sand shown on the section. There was then, says Mr. Chaudron, a moment of discouragement, or, at least, of cruel deception. But, he adds, as soon as the first instant of dismay passed, we ardently set to work to find a means for getting through these Aachen sands. The work of sinking, then, comprised two quite distinct stages: (1) Sinking with the shaft full of water down to 292 metres; (2) sinking through the quicksand, and into the coal-bearing rocks to a depth of 324 metres, where a bottom for the tubbing was found.

This is not the place to enter into full details of this subject. It will be understood that the idea of Mr. Chaudron and the engineers who assisted him in his arduous task was to prevent the caving in of the sand as the boring proceeded. They succeeded in sinking telescopic sheet iron cylinders, as had already been done for the sands nearer the surface, but the operations were of course more difficult. Five columns of tubes were thus successively sunk to line the lower 38 metres. After this, the final tubbing was sunk to line the whole shaft to a depth of 324·30 metres, an operation that was crowned with success. Two shafts were sunk in this way to the coal measures. Work was begun in May, 1873. In January, 1874, the sinking plant was ready for work at No. 1 pit. It was finished in 1886, and No. 2 pit in 1887. These shafts are 50 metres apart from centre to centre. The interior diameter of the tubbing at the bottom is 3·65 metres, and this is increased to 4 metres higher up by putting in conical rings at different heights. The total weight of the tubbing amounts to 5000 tons, which cost from 25 to 27 francs. The thickness of the moss-box is 110 millimetres. These latter particulars were given by Mr. Sohier, the present director of the colliery, who has also stated that, according to the account books, the total cost of the sinkings amounted to 4,027,000 francs (£161,080), or an average of 6365 francs (£254) per metre run. This undertaking, Mr. Chaudron says, is by far the most important that has been entrusted to him since his system of sinking with water standing in the shaft has been in use. With this really remarkable example, it may be said that to-day any sinking might be undertaken by this process with every chance of success.

*Shaft at Houssu.*—A more recent process has been applied at the Houssu colliery under similar conditions as regards the stratification, but under much more difficult circumstances. This process was originated by Mr. Poetsch, a German engineer, who had already applied it on several occasions in his own country. Its principle consists in freezing a cylindrical mass in the watery quicksand, and in sinking the shaft in the solid. The means for doing this consist in sinking outside the periphery of the shaft a number of metallic tubes closed at the lower end. These tubes penetrate as far as the impermeable strata which is to constitute the foundation for the tubbing. Inside these tubes, which are about 0·20 metre in diameter, are placed smaller tubes open at the bottom, and extending nearly to the bottom of the outer tubes. A liquid, passing a very low freezing point, is forced into the inner tubes by a pump, and rises through the annular space between the two tubes. The cold liquid acting through the walls of the tubes lowers the temperature of the surrounding ground and freezes it into solid masses, isolated at first, and then joining into one large mass as the operation is prolonged. Finally a resisting cylinder is formed, and permits the shaft to be sunk within it down to the impermeable strata. The shafts at Houssu, as at Ghlin, have to pass through sands belonging to the Wealden formation, which are encountered at a depth of 61 metres below the same cretaceous strata. These sands are of various colours, sometimes clayey near the bottom, but always excessively loose and watery. Their thickness is 11 metres and they rest immediately on the coal series. When the quicksand was reached, the flow of water amounted to 16 cubic metres—3520 gallons—per hour, and it rose to a height of 7 metres. The shafts were to be 4 metres in internal diameter. Eighteen double freezing tubes were sunk in a circle of 5·12 metres in diameter. They started at a depth of 54 metres and reached a depth of 75 metres. A freezing machine on Kropff's system, using the alternate liquefaction and vaporisation of ammonia, was installed on the surface and started December 5th, 1885. It was of a size intended to freeze 450 kilos.—990 lb.—of water per hour; but as it was unable to cool the refrigerating liquid, which was a solution of chloride of magnesium, to − 10 deg. C., a second machine was added seven months afterwards. The lowering of the temperature could then be forced down to − 25 deg. C., which allowed the work to be successfully performed. The operation of freezing lasted from December 5th, 1885, to August 5th, 1887, at which date sinking was commenced. The pit was carried down to the coal measures, after which it was tubbed. The work was completely finished December 22nd, 1887. I would add that in February, 1888, the ground was sufficiently thawed for the withdrawal of the freezing tubes.

Such is a *résumé* of the work made from information supplied by Mr. Alexander, director of the Houssu colliery. The freezing process had not then been applied under such difficult circumstances, and it may be said that this success, which had been preceded by several failures in Germany, has decidedly caused it to rank as a workable method.

*Working at great depths in Belgian coal mines.*—In Belgium the necessity of carrying our coal workings to a great depth in the near future was forced upon us some time ago. Fifty years ago the science sections of the *Academie Royale de Belgique* discussed the means to be employed if workings were carried to a depth of 1000 metres. Professor Devillez, of the Mons School of Mines, whose recent decease is regretted alike by science and industry, answered this question, and proved that the means for extraction, sinking, and ventilation which existed at that time would suffice all needs. Since then these means have been improved, and the ideas of the illustrious professor are as accurate now as they were then. This statement is confirmed by recently installed plants, which I propose to briefly mention. Very shortly after the professor made these assertions, mining engineers no longer hesitated to attack these great depths.

*Shaft at Viviers.*—A shaft was sunk at the Viviers Consolidated Colliery, Charleroi, to a depth of 1140 metres—3750ft.—but unfortunately the expected deposit was not found, and the shaft was abandoned.

*Shaft at Viernoy.*—More recently the Viernoy shaft at the Anderlues Colliery was deepened to 1000 metres—3300ft.—and provisionally abandoned for the same reason.

*Produits shaft.*—The Produits Colliery has lately deepened the St. Henriette or No. 8 shaft, at the north of the royalty, to 1150 metres—3800ft. From this point an incline has been driven to a depth of 1200 metres—3950ft.—the greatest depth as yet reached in the Belgian coal field. In spite of the somewhat restricted dimensions of the shaft, it is hoped that a considerable output will be reached. The workings, however, are in a preparatory stage only, so that I cannot dwell further on this subject. In all instances where the workings are comparatively important, and it is desired to increase the output, it has to be done at depths which, if they do not actually reach 1000 metres, are not far from it. Quite recently this question has presented itself under a different aspect. Apart from the power of the winding engine itself, the quantity extracted diminishes in proportion to the depth, on account of the fact that the original dimensions of the shaft have to be preserved as it is deepened. The shafts are thus somewhat narrow throughout, and this state of affairs will have to be remedied, as it is impossible to use cages carrying two tubs abreast.

*Shaft at Marchiennes.*—Here a problem was presented to Mr. Alfred Soupart, director of the Marchiennes Colliery, and he solved it in a daring and somewhat unexpected manner. The circumstances were as follows:—There were two shafts at this colliery, one 900 metres—3000ft. deep—elliptical in cross section, and from 2·60 to 2·80 metres long; the other circular, with a maximum diameter of 3 metres. From these shafts a very good deposit was worked, giving a large output. Mr. Soupart determined to use both of these as winding shafts, the upcast continuing to be used as such by applying Briart's ventilation trap. In the future these shafts will be carried to a depth of 1200 metres at least. The condition of large output—say 1000 tons daily—could not be met by the then existing four-decked cages, carrying one tub on each deck, except by increasing the engine speed beyond the permissible limit. It was therefore determined to increase the height of the cages to ten and twelve decks respectively. The landings at the surface and the insets at the bottom of the shaft have been increased in number, and the pit-frames are 25 and 30 metres high at the two shafts. The guides are solidly constructed of Vignoles rails in two ways. At No. 1 shaft the rails are opposite one another, and consequently the cages are guided at their ends. As the passing of the cages is very difficult in some confined portions of the shaft, recourse is had to the Soupart system. At No. 2 shaft, Briart guides have been put in. The cages with ten decks weigh 3500 kilos.—7700 lb.—and the twelve-deck cages weigh 4000 kilos.—8800 lb. The dead weight with the empty tubs are 6000 kilos. and 7000 kilos.—13,200 lb. and 15,400 lb.—respectively. The loads amount to 5000 kilos. and 6000 kilos.—11,000 lb. and 13,200 lb. The time occupied in changing is 120 seconds at No. 1 shaft, and only eighty seconds at No. 2. For winding, 120 seconds are required. The total time for each journey of a cage is thus four minutes or more. The output at the present time is from 700 to 800 tons per day, and shortly a total of 1000 tons will be reached. In case of accidents at No. 1 shaft, No. 2 shaft will still give a very considerable output.

*Introduction of machinery in the mines.—Underground haulage.*—Numerous applications of steam-power to transport and drainage have been made in English mines. In Belgium, however, we have long hesitated to introduce underground engines on account of the relatively large excavations required for such machines in England, to which it was thought, and justly so, that our rocks would not lend themselves. It is therefore necessary to limit the excavation and to reduce the dimensions of the motors, of which the construction has to be modified, in order to suit the new conditions imposed upon them. I shall only very briefly mention haulage machinery which is thus introduced in the mines. The engines often occupy a very limited space, although they work the haulage over several kilometres. These machines are now part of our regular equipment, and they work the several known kinds of rope or chain haulage.

*Machinery for underground drainage.—Pumps at the St. Katherine shaft at Bascoup.*—Pumps were slower in becoming acclimatised on account of the difficulty in reconciling the conditions of restricted space with mechanical efficiency. This has been done, however, and as an example I may cite the drainage machinery at the St. Catherine shaft of the Bascoup Colliery, which lifts the water to a height of 360 metres—1180ft. It is installed in a brick-lined gallery of 2·25 metres in interior diameter. The usual foundations, which take up so much room, are omitted, and instead, the machinery is bolted down on strong iron beams solidly built into the masonry. The principal parts of the engine, steam cylinder, condenser, and pumps are arranged tandem-fashion. The principal dimensions are as follows:

| | |
|---|---|
| Diameter of steam cylinder... ... ... ... | 0·67 metres |
| Stroke of steam piston and pumps ... ... | 0·65 ,, |
| Revolutions per minute... ... ... ... ... | 40 to 50 |
| Diameter of the pump cylinders, which are placed side by side ... ... ... ... ... | 0·175 metres |
| Diameter of the condenser ... ... ... ... | 0·320 ,, |
| Diameter of delivery pipes ... ... ... ... | 0·147 ,, |
| Diameter of steam pipes ... ... ... ... | 0·143 ,, |
| Theoretical yield per revolution ... ... ... | 26·16 litres |
| Theoretical yield per minute at 50 revolutions ... ... ... ... ... ... ... ... | 1·308 cub. metres. |

An air reservoir is placed at the bottom of the water column to lessen shocks.

*Pump at La Louvière.*—Another underground pump installed at the La Louvière collieries is still more remarkable, as much on account of its power as of the height of throw, which is 576 metres in a single lift. The following are some of the principal details:—

| | |
|---|---|
| Diameter of motor cylinder ... ... | 0·75 metres. |
| Stroke of piston and pumps ... ... | 0·60 ,, |
| Diameter of air pump .. ... ... | 0·26 ,, |
| Diameter of pump piston... ... ... | 0·11 ,, |
| Diameter of lift pipe... ... ... ... | 0·15 ,, |
| Diameter of steam pipe ... ... ... | 0·195 ,, |
| Revolutions... ... ... ... ... ... | 48 to 68 metres. |
| Theoretical yield per hour ... ... | 43·77 to 62·01 cu. metres |
| Practical yield per hour ... ... ... | 32 08 to 59 55 ,, ,, |

| | |
|---|---|
| Indicated power, horse-power... ... | 117·5 to 167·24 |
| Work in water raised, horse-power | 83·40 to 127·24 |
| Efficiency ... ... ... ... ... ... | 71 to 76 per cent. |

A Baer accumulator replaces the air reservoir to reduce shock and to regulate the movement of the water in the pipes.

Many other underground pumps are at work in Belgium at the present time, all of which are constructed on analogous principles on which it is unnecessary to dwell further.

*Electricity.*—Electricity also has found its way into our mines for generating both power and light. I do not think that the time has yet come to say much about it. All that can be said is that tentative efforts are full of promise for the future.

*The treatment of coal—coke and briquettes.*—Perhaps it is for the reasons set forth above that we find ourselves forced to push the treatment of coal to such extreme limits. It was in Belgium that the classification of coal was primarily carried on to the extent that is seen at the present, and that mechanical sorting originally found such an extended field. It is here that the need for washing the coal, not only prior to its direct sale to the public, but especially before its manufacture into coke and briquettes, was first felt; and it is here also that coke ovens and briquette presses were investigated and improved in order to give the greatest degree of economy. Fifty years ago the manufacture of agglomerated coal, or briquettes, was installed in the district of Charleroi. This industry has grown largely in our country, and it will grow more and more. The need for turning part of the small coal into a more useful form has begun to appear even in more favoured coalfields. It is about thirty years ago that the Belgian engineers, Smets, Dulait, and Coppée, recognised the necessity for using, in the manufacture of coke, those coals which until then had been rejected as insufficiently bituminous. All of them sought to improve the coke oven, and the latter invented the type which we now see adopted everywhere. These apparatus are too well known for us to dwell on here, and I must hasten on to the principal point of which I have to treat.

*Fire-damp and ventilation.*—The history of fire-damp in Belgium can be subdivided into two entirely distinct periods. The first extends from the earliest times up to the year 1847, when the first sudden outburst took place in the Mons seam; and the second from that year until the present time. Several years ago, experiments made in Wales drew the attention of engineers to the function of the very fine and often impalpable coaldust suspended in the air of mines. The experiments were repeated in other coal-producing countries, and in spite of the sometimes contradictory results that they have given, it is now admitted that if these dusts are not explosive by themselves, yet they greatly aggravate explosions of fire-damp when mixed with it, and that, above all, they act to propagate the explosion.

*First period: Slow disengagement.* — Let us here recall the fact that Belgian coals are more dusty than any others, and that this condition tends to increase with the depth. This first period was characterised by gaseous liberation more or less active, but always increasing, and without abruptness. It was admitted in principle that, besides the precautions necessary to protect the gas from contact with any kind of flame, a sufficient and continuous ventilation was sufficient by itself to preserve the miners from the attacks of their constant enemy. The introduction of the Davy lamp into collieries, in spite of the improvements embodied in it, only offered a relative and sometimes doubtful security. The real safeguard consisted in removing the gas from the workings in proportion to its production. I believe I can say with truth that although the glory of having given us the safety or Davy lamp belongs to England, Belgium, in spite of the small extent of her territory, has produced the greatest number of ventilating appliances. Amongst us was first felt the necessity for getting rid of the inefficient and dangerous ventilating furnaces. I must not, however, recall all that has been done in this way, as it has scarcely more than a historical interest. In order to restrict myself to one apparatus that has lived, I will merely mention the Guibal fan, which is universally known and applied. For several years other apparatus, whose chief feature is their smaller bulk, have come to us from other countries, and are running side by side with it. I may instance the Rateau fan, which in addition appears to have the advantage of greater efficiency. If this is really so we shall cordially adopt it, in the belief that we must above all things keep in view the good ventilation and safety of our mines. But if the Guibal fan has to give place to other and more perfect apparatus, the illustrious professor of Mons will still retain the lasting glory of having contributed more than any one to the establishment of the true principles of ventilation and circulation of the air in mines. I must, however, not forget to remind you of what has been done to prevent the ignition of fire-damp by explosives. In this connection I may mention mechanical drills, which, when used in conjunction with wedges, allow us to get through substances that have been the cause of so many accidents. I must also refer to the Thomas-François apparatus, which has replaced explosives not only in the seam itself, but also in driving stone-drifts.

*Second period: Sudden outbursts.*—According to Mr. Gustave Arnould, no outburst of gas had been observed prior to 1847. At first such outbursts occurred on a small scale, and attracted but little attention. In 1865, in a colliery in the Mons district, the first outburst of this kind took place, under strange and altogether extraordinary circumstances. Other explosions soon followed, and caused some of the most dreadful catastrophes that have ever occurred in mining history. The gas showed itself under entirely novel conditions, of which our country seems to have kept the sad and terrible monopoly. Sudden outbursts of enormous quantities of fire-damp occur simultaneously with the extensive projection of broken coal, and this takes place without any warning signs. Floods of inflammable gas invade the roads, the intakes, as well as the return air-ways, driving back the air current, rushing up the down cast shaft, and sometimes taking fire at the furnaces on the surface. It is needless to say that in such a case everything is destroyed, especially the winding gear, which is so urgently wanted on these occasions for getting the men out of the mine. Everyone is overwhelmed in the presence of the enormous jet of flame rushing out of the pit, and lasting as long as the outburst itself. The quantity of gas evolved during this phase of the phenomena has been estimated at 2400 to 3000 cubic metres—84,700 to 106,000 cubic feet—per minute, an astonishing amount that is, however, only an average. What, then, can be the volume in the first stage of the outburst, at the moment of explosion? In the presence of such accidents, it has been and still is asked whether science can ever succeed, not in preventing their recurrence, but in rendering them harmless. To increase the ventilation is altogether illusory in the presence of such enormous quantities of gas to be diluted with air. The best means that has been found up to the present is to keep boreholes in advance at every working face with the idea of draining out the gas from the strata, to restrict the advance, and to so dispose the air-ways that the air-current cannot be reversed. According to official statistics, the application of these measures has already had good results, and the number of victims has sensibly diminished. In all cases, in spite of the most disadvantageous conditions, and above all, of the extremely dangerous work in our collieries, it would be erroneous to suppose that accidents are proportionately more numerous than in other coal districts. As a matter of fact, we find in the *Statisque des Mines, Minières, Carrières*, published by Mr. E. Harzé in 1891, a table giving the average of the number of miners killed yearly during the decade 1881-90 in Belgium and in the neighbouring countries. The average is:—

| | | |
|---|---|---|
| Belgium ... ... ... | 19·92 | per 10,000 workmen employed |
| France ... ... ... | 18·53 | " " |
| Great Britain ... | 19·36 | " " |
| Prussia ... ... ... | 29·34 | " " |

I will stop at this point, gentlemen, and pray you to pardon me if I have wasted the time that you could perhaps have better employed, but you will remember that if coal is the bread of industry in general, it is peculiarly necessary for metallurgy. I have attempted to show you our coalfields as they are, and to demonstrate the difficulties that we have to overcome, difficulties that are unquestionably greater than elsewhere. If we keep our ground under such unpropitious circumstances we can only attribute it, I think I may safely say, to the initiative of our manufacturers, to the knowledge and experience of our engineers, whether in private practice or in the public service, and to the remarkable skill that, in consequence of the difficulties themselves, our industrial population has acquired. Nor must I forget the instruction in mining and in the collateral sciences that is afforded at the two older Mining Schools of Belgium, that of Liége and that of Mons. They have had the good fortune to have had for very many years the instruction entrusted to men of the highest eminence. I have already had occasion to cite the names of Devillez and Guibal, and may be permitted also to refer to that of Mr. Trasenster, who was entrusted with the instruction at the Liége School of Mines at about the same period. A man eminent for his knowledge and for his clear perception of practical requirements, he was a professor without an equal, and deserves to remain life-long President of the Society of Engineers who have graduated from that school."

Sir Lowthian Bell's paper "On the Use of Caustic Lime in the Blast Furnace" was a continuation to that "On the General Economy of the Blast Furnace," read at Darlington last autumn, and besides the special subject indicated in the title, incidentally touched upon the irregularities due to want of uniformity in heat caused by the use of fire-brick stoves, and the increased liability to "hanging" of the charge consequent on the introduction of very hot air in melting. He is still of opinion that the production of pig iron for Cleveland ore can scarcely be effected by less than 20 cwt. of coke per ton for any long continued period, and at Clarence he has scarcely brought it below 21 cwt. As regards the main question of the paper, observations carried on for nineteen weeks on two furnaces using limestone, and two others for seventeen weeks on lime not perfectly calcined, showed that 1·87 units of coke less were required for 20 units of pig with caustic lime. The quality of the work was about the same in each case, and the coke saving was 8·55 per cent. As a matter of commercial policy there was not much to choose between coke in the furnace and coal in the kiln. Small coal used in the kiln is only half the price of coke, but twice as much of it is required to do the same amount of work. To obtain 10,988 tons of lime 2922 tons of small coal were required, costing £838 15s. 9d., or 1s. 6½d. per ton of lime, or per ton of iron made 7·59d. The labour cost is small, but something must be added for wear and tear of the kiln.

In the discussion the President called upon Mr. David Evans, who stated that experiments carried on for six months, thirty years since in Cleveland, showed that no appreciable advantage was to be obtained from the use of caustic lime. Mr. Julian Kennedy and M. Jules Greeiner made a few remarks, without contributing any matter of importance to the discussion; the only speaker on the other side of the question being Mr. C. W. Wood, who stated that he began using caustic lime in his furnaces twenty-five years ago, and had found it sufficiently advantageous to continue the practice ever since. He has, however, introduced an important modification—to which probably his success is largely due—namely, the calcination of the ironstone and limestone simultaneously in the same kiln, which, as pointed out by Sir Lowthian Bell in his reply, utilises the heat developed by the oxidation of ferrous to ferric oxide, after the decomposition of the carbonate of iron. A long note from Mr. Cochrane, in reply to the paper, was presented to the meeting; but as it was impossible to read it, it was decided to print it, so that the discussion on the question may for the present be considered as adjourned.

The third paper read on Tuesday was by Mr. T. W. Hogg, of Newburn Steelworks,

### "ON THE INFLUENCE OF ALUMINIUM UPON THE CARBON IN FERRO-CARBON ALLOYS."

The question, the author said, whether aluminium of itself is capable of producing a change in the condition of the carbon when added to ferro-carbon alloys is one of considerable interest, and as it appears to be generally accepted that the addition of aluminium to white iron causes the carbon to be changed to the graphitic state, it is important to ascertain whether the results which have been obtained by different observers are particular cases only, or whether this property of aluminium may be taken as a general law. Having detailed the results obtained by previous observers, the author went on to say that it appeared that the preparation of a series of alloys containing aluminium in different proportions, and as far as possible keeping out the silicon and manganese, would give results of much interest; and for the opportunity of carrying this out he had to thank Mr. J. W. Spencer, the managing director of the Newburn Steelworks. Two kinds of pure Swedish pig iron were used, one a highly saturated grey pig, and the other a white variety showing a litle grey towards the centre of the pigs. The composition of each is shown in the following table:—

TABLE I.

| | Grey. | White. |
|---|---|---|
| Iron (by difference)... ... ... ... ... | 94·707 | 95·665 |
| Manganese... ... ... ... ... ... ... | 0·22 | 0·11 |
| Carbon (graphitic) ... ... ... ... ... | 3·75 | 0·40 |
| Carbon (combined) ... ... ... ... ... | 0·58 | 3·27 |
| Carbon (total) ... ... ... ... ... ... | 4·33 | 3·67 |
| Silicon ... ... ... ... ... ... ... | 0·70 | 0·48 |
| Sulphur ... ... ... ... ... ... ... | 0·005 | 0·01 |
| Phosphorous ... ... ... ... ... ... | 0·038 | 0·065 |
| | 100·000 | 100·000 |

The several alloys were prepared by fusing the iron in clay pots, and with the exception of the one containing 1 per cent. aluminium, this metal was separately melted and the iron poured into it; the mixture was then again poured back into the pot, and this operation was repeated twice. The alloy was next poured into two moulds, one of iron and the other of green sand, in order that one portion should be cooled rapidly, and the other slowly, and this was done without the addition of any aluminium. The alloys were prepared in quantities of about 60 lb. each, and cast into 3in. square moulds. The quantity of graphite, carbon, and silicon determined in each case were given in a tabular form.

It is to be observed that the most effectual primary change in the condition of the carbon is obtained by the addition of 1 per cent. of aluminium, and each addition after this causes more and more of the carbon to pass into the combined state, until practically the whole of it is in this condition in the 12 per cent. alloy. In all cases the rapidly cooled alloys show a remarkable excess of graphitic carbon over that contained by the slowly cooled alloys; this is the most decided in the case of the alloy with grey pig iron containing 4 per cent. aluminium. As there are so many examples of this, it would be interesting to have a satisfactory explanation, as the phenomena is quite unique. May it not be that the aluminium has actually caused a precipitation of carbon in the molten alloy, and the more slowly cooled portions have partially taken up the carbon again by cementation? It is also to be observed that the total carbon in the case of the white pig alloys is not diminished, any more than that produced by admixture of an element not containing carbon; but in the case of the grey pig high percentage alloy there is a decided loss. The addition of 12 per cent. aluminium to pig iron containing 4·33 per cent. carbon should cause this element to be reduced to 3·80 per cent., whereas only 3·44 per cent. was found.

The general effect of the more rapid cooling upon the fractures has been to produce a much closer grain, and here an interesting fact is well illustrated. He alluded to the deceptive nature of the fractures as an indication of the proportion of graphitic carbon, a circumstance first pointed out by Bell.

In the case of the higher percentage alloys there was an evolution of large quantities of gas on solidification, and although the lower portions of the ingots were perfectly sound, the top portions even on the outside showed numerous honeycombs, completely filled with minute glistening flakes of graphite; in this respect, therefore, the high aluminium alloys resemble the high silicon alloys. This phenomena, however, is not a case of actual separation of graphite from the alloy, but decomposition of the issuing carbonic oxide.

Hadfield has described an interesting experiment wherein aluminium was added to spiegeleisen, with the result that the condition of the carbon and appearance of the fracture was greatly altered, but as it is well known that prolonged fusion of spiegeleisen itself may produce an alloy which is often more or less graphitic in its nature, and in addition to this the quantity of silicon present in his alloys seemed high in proportion to the aluminium, it appeared to be of interest to ascertain the effect of remelting a 4 per cent. aluminium alloy alone, and also with the addition of a considerable quantity of manganese; in each case two ingots were cast to determine the difference between rapid and slow cooling, as in the other alloys.

There is three times as much graphitic carbon present in the more rapidly cooled portion of the alloy; the slowly cooled alloy is very unsound, and the general appearance of the fracture would certainly lead one to expect to find it the reverse of what is actually the case; so far as

"THE ENGINEER" SWAIN ENG

the proportion of graphite is concerned, this alloy is a beautiful illustration of the fact noticed by Bell, and previously alluded to. To ascertain the influence of aluminium upon a high silicon alloy, ferro-silicon was fused and mixed with 4 per cent. aluminium also previously fused; two ingots were prepared as in the other alloys to determine the difference, if any, between rapid and slow cooling. Beyond showing a great change in the grain of the alloy, the result does not give any further important information. The slowly cooled portion was much honeycombed, the cavities being lined with graphite. The rapidly cooled portion appears to be perfectly free from any unsoundness, and the change from the original appearance of the alloy is most marked.

In conclusion, it is shown in the present paper that in the purer classes of pig iron all tendency for carbon to be retained in the combined state is prevented in the most decided manner by the addition of 1 per cent. of aluminium, and that every increase upon this quantity tends to reverse this effect, until, with a large proportion of aluminium, the carbon in white pig iron is retained in its original condition, and the graphitic carbon present in grey pig is entirely changed to the combined state. It is suggested that the exact points for the complete change in each case will vary with the different kinds of iron and the degree of saturation with carbon. The interesting fact is described that the more rapidly cooled ferro-carbon alloys containing aluminium contain a larger proportion of graphite.

Mr. Snelus said that Mr. Hogg's efforts were worthy of much praise. It was only by experiment that advances could be effected in science. Mr. Hogg's results opened new ground for inquiry and investigation. It was very remarkable that an increase of aluminium above 1 per cent. should neutralise the effect produced up to that percentage. Aluminium had previously been tried with steel, and it produced a remarkable effect, but it did not form an alloy; it was all burned out, removing oxygen. Mr. Hogg did form an alloy. More time and experiment were needed. He suggested that some of the large surplus funds of the institution should be devoted to the purpose. Indeed, he did not think the money they had could be more usefully employed than in carrying out experiments. Mr. Perry Nursey supported this suggestion.

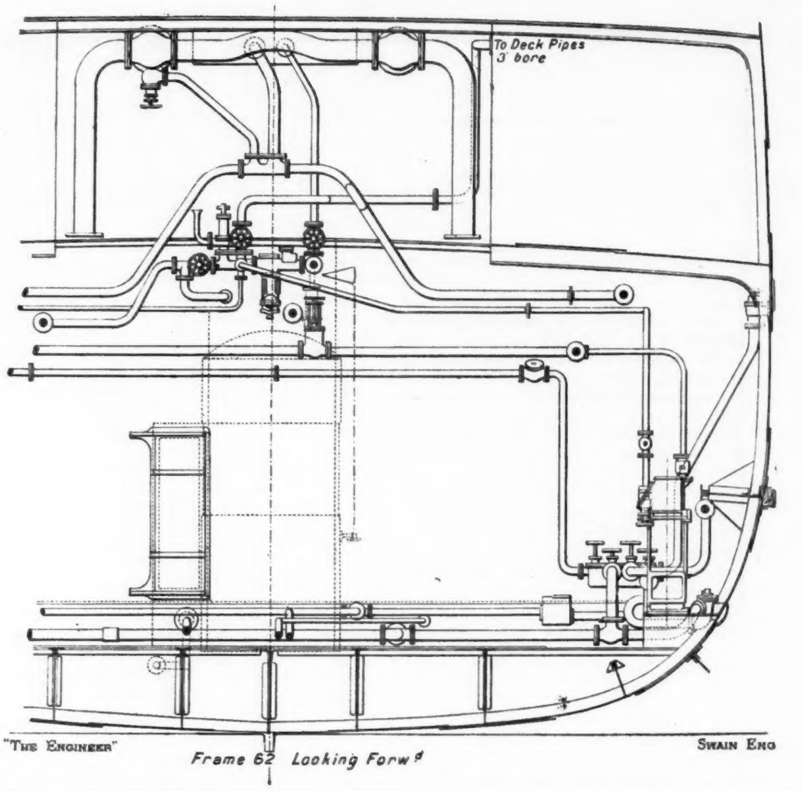
Professor Howe said that under certain conditions aluminium did no doubt favour the separation of graphite, and it was used on a commercial scale in the United States on certain classes of castings for that purpose. He did not think the result of sudden cooling, considered by Mr. Hogg to be unique, was really so. The idea that sudden cooling reduced segregation was little more, he considered, than a theory. There was no doubt that in some forms of pig iron slow cooling and segregation went together, but that was, so far, exceptional.

Professor Turner referred to the effect produced by silicon, which, used in small quantities, produced an effect which was diminished by further additions. He cited Holgate's very complete series of analyses, and was surprised that Mr. Hogg had not mentioned them. Manganese tended to make certain common irons with a strong tendency to whiteness and chilling grey. Some years ago there was used in Birmingham and the district a powder which, when put into a cupola, greatly improved the castings. The composition of this "physic" did not long remain a secret. It turned out to be nothing but ferro-manganese in powder.

Mr. Hogg very briefly replied. The graphite, he said, was found in the cavities, not in the mass of the iron. The cavities were filled with it. What Professor Turner had said was interesting but indefinite. The President proposed a vote of thanks both to Mr. Hogg and to Mr. Hadfield, whose valuable paper was taken as read. These were passed unanimously, and the meeting adjourned, proceeding to Antwerp by a special train at 2 p.m.

## S.S. DUKE OF YORK — CONDENSER AND HEATER CONNECTIONS

(*For description see page* 147 *ante*)



## THE BRITISH ASSOCIATION AT OXFORD.

A DISTINCTIVE feature of the recent British Association meeting at Oxford was the unusually good attendance at the more technical of the Sections, showing better education among the temporary members in particular directions. On the first day of the meeting of the Sections, Section A is usually well attended for the first hour, probably because the letter A has precedence over the letter B, but after the first morning Sections A and B are usually pretty severely let alone, and the temporary floating population of the Association gravitates to the Geographical Section and to the Anthropological Section; in the latter a discussion on men and monkeys, or on prehensile babies, or on the phenomena of ticklishness, are sure to draw a full house. At Oxford, not alone were there large attendances throughout at Section A, but the papers therein were so numerous that for the first time in the history of the Section, on some days it was obliged to sit in triplicate—in three divisions at the same time—to get through the work. Nor was this all; every day it began its work either an hour or half an hour earlier than the other Sections, and sometimes sat later than its neighbours. This was to the inconvenience of those members who wanted occasionally to be elsewhere, and on some days the proceedings were so prolonged as to be thoroughly wearisome. The fact is that the title of Section A, "Mathematical and Physical Science," includes too many subjects, and the meetings of the Section have attained unwieldy and unmanageable dimensions; Section A needs breaking up into smaller permanent divisions, so that for the comfort of the members of the Association it shall keep the same hours as its more fortunate brethren. The application of "the closure" to some of the discussions might expedite work; it was frequently desirable at Oxford

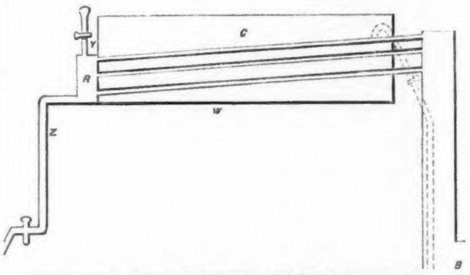
One or more of the London daily newspapers had an announcement of "two" great discoveries made known at the British Association on the same day; the one was the "new gas" in the atmosphere; the other, so it was published, is that the atomic weight of carbon is six, as it was considered to be in the olden time, and not twelve. This announcement originated with a paper read at Section B by Mr. J. A. Wanklyn, in the course of which he said:—"I have now to announce that as the result of most laborious investigation carried on conjointly with my friend and colleague, Mr. Cooper, there exists a multitude of carbon compounds wherein the quantity of carbon in the standard volume is not a multiple of 12, but is a multiple of 6. And the consequence follows that the atomic weight of carbon is 6, as was commonly believed by chemists a third of a century ago. Here is one of these carbon compounds which we have labelled Aa, its formula is $C_{7\frac{1}{2}}H_{15}$, writing the notation in vogue at the present day. We have six other half-carbon substances, viz., $C_{8\frac{1}{2}}H_{17}$; $C_{9\frac{1}{2}}H_{19}$; $C_{10\frac{1}{2}}H_{21}$; $C_{11\frac{1}{2}}H_{23}$; $C_{12\frac{1}{2}}H_{25}$; $C_{13\frac{1}{2}}H_{27}$. The following are the vapour-densities as found and as required by theory:—

| Found. | Theory. |
|---|---|
| 3·69 | 3·63 |
| 4 08 | 4·11 |
| 4·59 | 4 59 |
| 5·02 | 5 08 |
| 5 51 | 5·56 |
| 6 08 | 6 04 |
| 6·53 | 6·52 |

These hydrocarbons exist in the Russian kerosene of commerce, from which they have been extracted by laborious and methodical fractional distillation. Further particulars of the investigation, which has occupied nearly two years, are to be read in the *Philosophical Magazine* for the month of May last, to which reference may be made."

Dr. William Odling, F.R.S., who for so long has disappeared from the Royal Institution and other halls of science in which his face was once so familiar in London, has been for several years, and is now, a Professor at Oxford. In his criticism of the paper, he said:—"In order to arrive at a conclusion of such importance, we must have a great deal more than the boiling point and vapour density. We know that a great number of vapours are mixtures of closely allied bodies, and that the boiling points may be for a long while perfectly invariable, and nevertheless not be the boiling points of one substance, but the boiling point of a mixture of several substances. As I understand, this body in the bottle before us contains of 7½ atoms of carbon, or 15 atoms to the value of 6. If Mr. Wanklyn had from this produced a chloride in which one-fifteenth of hydrogen had been replaced by chlorine, and if from that he had got the alcohol and the aldehyd acid, and so on, and made out the metamorphic relations of these compounds, it would have been very different. But it seems almost preposterous for one to give up such well-established conclusions on such very slender evidence; the evidence must be much stronger in order to convince chemists that the body before us is constituted of 7½ atoms or 15 reduced atoms of carbon."

Messrs. Wanklyn and Cooper used a remarkably ingenious still, of their own invention, in their fractional experiments. Outside it looks like an ordinary still, but it automatically distils liquids in a partial vacuum of its own production, so that low temperatures can be used. Its construction may be explained by the accompanying diagram, in which B is the boiler, and C are three rows of condensing tubes—about a dozen in each row—passing through the tank W. The distillate falls into the receiver R, and conveyed through the pipe Z into a storage tank; Y is an air tube with a stop cock. The inventors say that they find in practice that a great economy of fuel attends the entire arrangement. An important feature of the improved still is that it admits of the easy performance of the distillation at pressures below the ordinary pressure of the atmosphere. If the pipe Z be so prolonged as to furnish a vertical column of liquid 40ft. in perpendicular height, then the distillation may be so managed as to be distillation in approximate vacuum. And if the receiver R be furnished with a suitable pressure gauge or monometer, the distillation may be conducted at any desired degree of reduced pressure by proper manipulation of the two stop cocks in Y and Z. The still creates and maintains its own vacuum. They find that a marked improvement in the quality of the product is obtained by working their improved still at reduced pressures. When heating petroleum liquid, say, for example, "Russian kerosene," the liquid is boiled in the boiler B, and the condenser W is filled with that liquid in a cold condition. The distillate is received in the receiver R, and conveyed through pipe Z into a storage tank, and the liquid employed for cooling is drawn off and replaced.



WANKLYN AND COOPER'S FRACTIONAL STILL

One part of the report of the British Association Committee on "Meteorological Photography," read before Section A by Mr. A. W. Clayden, set forth that—so far as it knew—the only measurements of cloud altitudes which have been systematically organised in this country are those which were begun some years ago at Kew, and it is desirable to have them from other places than near London, for comparison. It has been found easy to obtain well-defined images of clouds, even when the sun is in the centre of the field of view. If, then, two such photographs be taken simultaneously by a pair of cameras some distance apart, there will be a displacement of the image relatively to that of the sun, the amount of which displacement will depend upon various conditions. It will be increased by adding to the focal length of the lens, and by increasing the distance between the cameras. By knowing these values, and the altitude and azimuth of the sun, the distance of the cloud and its altitude above the ground may be calculated. The azimuth and altitude of the sun at the time may be ascertained by calculation, or by direct observation. There seems to be a manifest advantage in thus using the sun as a fixed point of reference, since it provides a means whereby any error in the observation of altitude and azimuth may be effectively checked. The Committee has therefore provided suitable cameras, with lenses of 18in. focus, covering a whole-plate size; the lenses have adjustable shutters which can be simultaneously freed by electrical attachment. At the short distance of 35 yards, they give a displacement of half an inch with clouds 3780ft. distant; this is too small for very accurate measurement, especially with high-level clouds, so it is intended to use them on a plot of level ground by the side of the South-Western Railway near Exeter; this strip of ground is over a quarter of a mile in length, and the cameras can be placed due east and west. This is a different method of measuring the height of clouds to that employed at Kew.

## IMPROVEMENTS AT THE WEST INDIA DOCKS.

The new Blackwall entrance to the West India Docks was formally opened on Thursday, the 16th inst. This well-known dock, the Act for which was passed in 1799, was opened in 1802, and is situated between Limehouse and Blackwall on the Thames, and, as will be seen from the accompanying small map, Fig. 1, by its existence gives the Isle of Dogs an insularity which it never otherwise possessed. It occupies an area of 164 acres, 70 of which are water, and really comprises two docks, which run parallel to each other, viz., the West India Import Dock and the West India Export Dock, each having an entrance to the basin at Limehouse and the basin at Blackwall, and thence from each basin to the river. Adjoining the Import Dock on the north side are eleven warehouses which, with this vast shipping basin, have for many years practically been lying idle, owing to the depth and entrance capacity of the latter being quite insufficient. In March, 1892, the Joint Committee, on the recommendation of Mr. H. W. Williams, the manager, decided, in consequence of the increasing size of vessels, to construct a new and larger entrance at Blackwall, and plans were prepared by Mr. Robert Carr for the construction of a new lock, 480ft. long, 60ft. wide, and 30ft. over the sills. When Messrs. Lucas and Aird, the contractors, commenced to drive the dams for the entrance lock, Mr. Carr was taken ill, and at the end of 1892 was appointed consulting engineer, the actual work of supervision being untertaken by Mr. H. F. Donaldson.

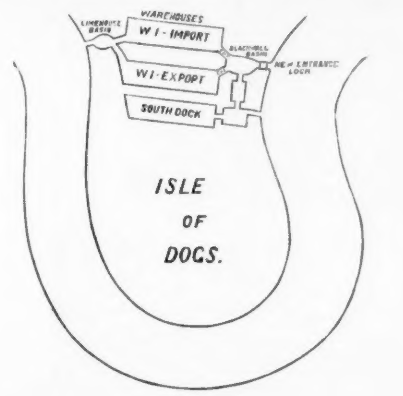


Fig. 1

The new entrance lock opens from the river into the Blackwall basin, and communicates from that basin by means of two new cuts with the Import and Export docks respectively. As at first planned, the cuts were to have been short locks, but the directors decided that they should be open, without gates, the length being insufficient to provide lockage, while, except as a safeguard, locks were considered unnecessary. It was also proposed at the outset that the entrance lock, which is 60ft. wide, should be 450ft. long, but eventually it was resolved that the lock should be 480ft., while the uniform depth of 30ft. over the sills will enable the docks to receive the largest merchant vessels trading to the Port of London. The dock gates, like those at Barry and elsewhere, are opened and closed by means of powerful direct-acting rams, which obviate the difficulty caused by the fouling of the twin screws of steamships when chains are used. Each direct-acting ram, of which there are four, one to each gate, works upon a bridle attached to the heel post, and to a point about two-thirds the length of the gate from the heel post, which has a sufficient amount of play to take up any wear in roller path or heel, or any flotation should such occur from an exceptional high tide. These rams, together with all the hydraulic machinery at the Entrance Lock, have been supplied by Sir W. G. Armstrong, Mitchell, and Co., of Elswick, Newcastle-upon-Tyne. The sluices are ten in number, six being hydraulic direct-acting rams supplied by the same firm, and four hand paddles for use in case of a breakdown. These last were made by the Joint Committee in their own works.

The general design for the lock has not been departed from, except that the effective length has been increased by 50ft., but the Import and Export cuts have practically been entirely remodelled. The original design, with a view to economy, was for the adoption of sheet pile campshedding along one side of each cut, and the removal of the old wall, thus increasing the width to the above-named dimensions. The old wall on the other side was to have been left, and a portion only of the sills removed by divers. In this case the whole of the work would have been done in the wet, without the introduction of dams or excavation, other than the removal of the old wall, which would also have been done by divers. After mature consideration, however, the Joint Committee decided that this should be altered, and the whole of both walls removed from each cut and re-erected upon new lines with two concrete walls of approved section. These walls were designed to do without an invert except under the two railway bridges, where from the jar of the trains it was thought advisable to put in a piece of concrete invert. The widening of these cuts necessitated the lengthening of the railway bridges, which has been carried out by Sir W. Arrol and Company, without interfering with the railway traffic.

It may perhaps be of interest to quote the sizes of the old lock, which were, as to the Blackwall entrance, 191ft. 6in. long, 45ft. wide, and 23ft. 3in. deep, and as to the Import and Export cuts, the former was 162ft. long, by 37ft. 3in. wide by 24ft. 3in. deep, and the latter 160ft. long, by 38ft. wide, by 21ft. 9in. deep. The effective depth is to give an entrance throughout and in the Import Dock for vessels drawing 24ft. to 25ft. of water, which can be increased to 26ft. or 27ft. at pleasure. It must of course not be lost sight of that 18in. of the greater depth will be due to pumping; this pumping machinery, in addition to maintaining the increased level of the water in the dock, makes good the loss of water occasioned by the docking of ships in the neighbouring dry dock. The suction in connection with the pumps is drawn from the river, and the delivery is of a somewhat novel description, on the principle of the domestic bath. We describe it further on. Our plan and elevation—Fig. 2—show the general arrangement of the pumps, with their suction and delivery channels. As already mentioned, everything in the shape of walls, inverts, and so forth, has been carried out by the contractors. The following particulars of the pumping plant constructed by Messrs. Easton, Anderson, and Goolden, may be of interest.

There are four vertical spindle centrifugal pumps, driven directly by horizontal compound condensing engines. The delivery of each pump is 5000 cubic feet per minute, or about 8303·5 tons per hour, on a mean lift of about 7ft., which makes an hourly total for all four pumps of 20,000 cubic feet or 33,214 tons. The pumps will commence two hours previous to high water, and will continue during the two hours of the ebb. The speed of the pumps and engines on the maximum lift. will be 110 revolutions. The fans of the pumps are 74in. diameter, 20in. deep. The special feature in the arrangement of the engines is that the cranks are set opposite each other, the pistons moving in opposite directions, so that the moving parts being approximately the same weight, balance each other. The diameter of the high-pressure cylinder is 15in., that of the low 29in., and the stroke is 16in. The steam and exhaust pipes are so arranged that any one or more of the engines might be worked at a time. An independent horizontal air pump engine is provided, the injection water being taken from the outlet of the culvert from the pumps. The delivery from the pumps passes out of the engine house towards the dock to an 8ft. culvert close to the dock, through which it descends to the bottom of the dock, where a pipe 9ft. in diameter is laid across the bottom of the entrance to the dock, having four vertical outlets with hoods above them which deflect the water, the idea being to distribute it so that it shall not interfere with shipping. At the trial run made at the opening, it was observed that no disturbance was noticeable at the surface of the water. It is also hoped that this arrangement may tend to keep the entrance clear of mud. The steam for the engines at 100 lb. pressure is provided by single flue Cornish boilers 6ft. 6in. diameter, 33ft long, each fitted with eight Galloway tubes and Adamson's rings. The firing is effected by Vicker's mechanical stokers, into the hoppers of which the coal is raised by a Jacob's ladder and screw traverser. The gates have been designed by Sir Alexander M. Rendel, and constructed by the Thames Ironworks and Shipbuilding Company, and are semi-floating and double-skinned, built of iron where exposed to the water, and on steel frames where not so. The heel and mitre posts on the closing sill are of greenheart, and the hollow quoins and stone sill are of granite.

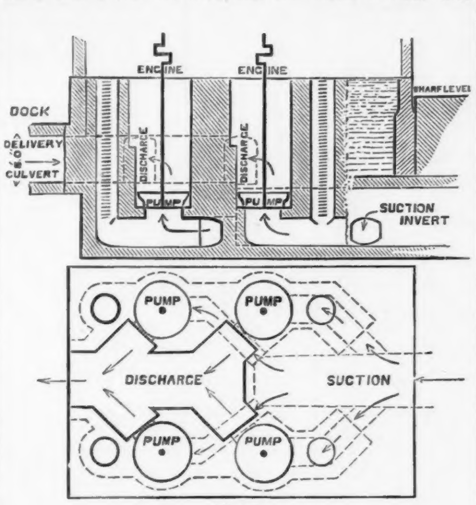

Fig. 2

It being necessary to deepen the Import Dock, a certain amount of dredging has had to be done to give the requisite depth. Before this work was commenced there were two rows of buoys in this dock, the majority of which have now been removed, and a lesser number of screw moorings of the most approved type are in course of being laid down in their place. It was also considered that the North Quay would not provide sufficient facilities for the class of vessels which it is hoped will now frequent this dock, and the extension of the quay for about half a mile of its length has been constructed for the Joint Committee by Mr. John Price, of Great George-street, Westminster. This extension is now being equipped with hydraulic movable cranes by Messrs. Tannett, Walker, and Co., of Leeds. These cranes will each be capable of dealing with 30 cwt., and any heavier lifts will, as in other docks, be dealt with by floating cranes.

It may be of interest to note that the original estimate for the work, viz., £200,000, has not been exceeded, and that the work has been actually completed within both the cost and time specified, notwithstanding that several material and costly additions have since been made to the design. The new entrance will be opened for the docking and undocking of vessels and barges on the 1st September, 1894.

## HARBOURS AND WATERWAYS.

*Harbour accounts.*—The returns of shipping for the past year which have been published show a decided improvement on last year. At Bristol the net amount to be met out of the city rates is £3964, against £18,288 in the previous year. The payments include a considerable sum which has to be paid to a sinking fund for repaying the money borrowed. If this be excluded, and the concern treated as an ordinary joint-stock company, the net revenue would be equal to paying a dividend on the capital of £2,100,000 of 2½ per cent., after allowing 4 per cent. on a proportionate amount of debentures and preference stock. The registered tonnage of vessels entering the port was 780,485, being the highest ever recorded, and an increase of 124,636 tons over the previous year. Including coastwise tonnage the total is 1,541,713. The increase is due chiefly to the expansion of the grain trade, the imports reaching 3,485,365 quarters, or more than a million greater than in the previous year. The import of petroleum also increased from 39,771 tons in 1893 to 42,141 tons last year. The imports of timber have increased, but provisions have decreased. On the Mersey there has been an increase during the past year of 40,231 tons, but this is 27,000 tons less than in 1892. The amount of tonnage on which rates have been paid during the year has been 9,960,902 tons, against 9,468,539 tons last year, and 9,968,697 tons in 1892. The coastwise tonnage constitutes about 28 per cent. of the whole trade. Coasting sailing vessels have fallen off 67,678 tons, but steamers have increased 22,620 tons. As at Bristol, the revenue depends largely on the import trade. The recent want of development in the shipping trade at Liverpool is accounted for by the greater facilities given on the Clyde and in the Thames and the Humber. It is estimated that the population for the district for which Liverpool is a distributing centre ten years ago was nine millions, about the same as that round London, but while the population round both centres has increased about one and a-half millions, the tonnage of the port of London has risen to 12,860,109, while that of Liverpool has only reached 10,600,076 tons. The recent report of the Chamber of Commerce of Liverpool seems to indicate that high charges, want of facilities for handling and transporting goods, and high railway rates, as compared with other ports, are the causes which are checking the growth of the trade of the docks. At Dundee there has been a falling off of revenue of £4630. This is accounted for principally by a diminished import of jute. On the Tyne, at the Commissioners' docks, for the first half of this year there has been an increase of ninety-two vessels, of 109,000 tons, in the vessels loaded and despatched, but a decrease of 8700 tons in the merchandise handled, and an increase of 149,800 tons in coal and coke. Owing to the erection of the new staiths at Dunston, the increase in the traffic in the upper part of the river has been very large. The Commissioners have given instructions for the dredging above Newcastle to be proceeded with as rapidly as possible.

*Aberdeen.*—A report has lately been made to the Harbour Authority as to the removal of the rock which constitutes the bed of part of the navigation channel, in order to obtain a depth of 30ft. at high water or spring tides, or 18ft. at low water. This rocky shoal extends continuously along the south side of the channel for a length of 1600ft., continuing westward for 300ft. in irregular detached masses. It consists principally of mica schist and gneiss. The surface is very irregular, being interspersed with cavities filled with clay. The total quantity of rock to be removed is estimated at 52,000 cubic yards. One hundred and thirty-five trial borings have been made, of which eighty-six were blasted, at a cost of £447, or £4 9s. 4d. per hole, the quantity of rock disturbed by blasting being 3½ cubic yards per hole. The estimated cost for blasting and dredging the rock with a single drill was 30s. per cubic yard. The rock drill used was suspended from the gantry of one of the hoppers, and was lifted at the rate of sixty strokes a minute by a steam winch.

*Leith.*—After the works for the construction of the new dock sea wall had been in progress for some time they were stopped, owing to the death of the managing partner in the firm of contractors who had undertaken the contract. The work was subsequently given to Mr. John Best, who has since been engaged in carrying it out. The amount to be paid to the representatives of the retiring contractors was left to be settled by Sir A. Rendel, the engineer of the Commissioners, and he has awarded that the sum of £8000 is due from the Commissioners to the late contractor for work done and plant on the ground. Messrs. Kinnear, Moodie, and Co. will lose several thousand pounds from this unfortunate stoppage and transfer of their contract.

*The Clyde.*—A commencement has been made with the new graving dock at Cessnock. It is to be 800ft. long, and will open into the new dock.

*Portsmouth.*—Mr. Kinniple has made a report to the Corporation on the proposed improvement of the Camber. The full scheme suggested is estimated to cost £70,000. It is now only proposed to dredge a channel 50ft. wide, and to widen the Camber so as to provide an increased water area of 2900 square yards, and also an improvement in the berthing accommodation available for large vessels at all states of the tide. The estimated cost of this work is £30,000.

*Workington.*—Negotiations have been going on for some time past between the Town Council and Lord Lonsdale as to the purchase of the dock at this port, which is his property. A report has now been obtained from Mr. Meik, C.E., as to the value of this dock and the cost of construction of a new dock. Mr. Meik puts the value of the existing dock at £75,066, and the cost of enlarging and making necessary alterations to bring it up to the requirements of the port at £149,000, a total of £224,066. The cost of converting the harbour into a dock and buying up Lord Lonsdale's interest he estimates at £279,706. The course Mr. Meik advises as giving the greatest advantage is the construction of an entirely new dock, the cost of which, with parliamentary and other expenses, is estimated at £214,282. The proposed dock would be 630ft. long by 500ft. wide, and to accommodate vessels 320ft. long, 40ft. beam, and 22ft. draught, capable of carrying 4000 tons.

*Copenhagen.*—It is expected that the new free port will be opened in the course of this year, or about twelve months before the opening of the North Sea and Baltic Canal. It is not intended that this new port shall be exempted from harbour and dock dues, but from customs duties. The new free port, with a certain amount of adjoining territory, will be totally exempted from all customs examination and control, and also from all customs duties, it being intended solely for the transit trade. Copenhagen has steamship communication with all the Baltic ports, with West Sweden and Norway, and with the most important European harbours, and with North America. Foreign steamers, of a total burden of 745,200 tons register, discharge at Copenhagen, a considerable part of their cargoes being passed on to the Baltic ports. The idea of establishing a free port for this transit trade is of long standing, but the construction of the North Sea and Baltic Canal, and the danger to Denmark from the threatened competition of Hamburg when the canal is opened, finally decided the Danish Government to undertake the works for the construction of the port, which will now soon be opened. The site of the new Free Port is to the north of the old harbour, and it has been constructed on land reclaimed from the sea. The water area is about 57 acres, and about 95 acres are included in the free territory. There are two basins, one 1300ft. long by 620ft. wide, with a depth of 24ft.; the other is

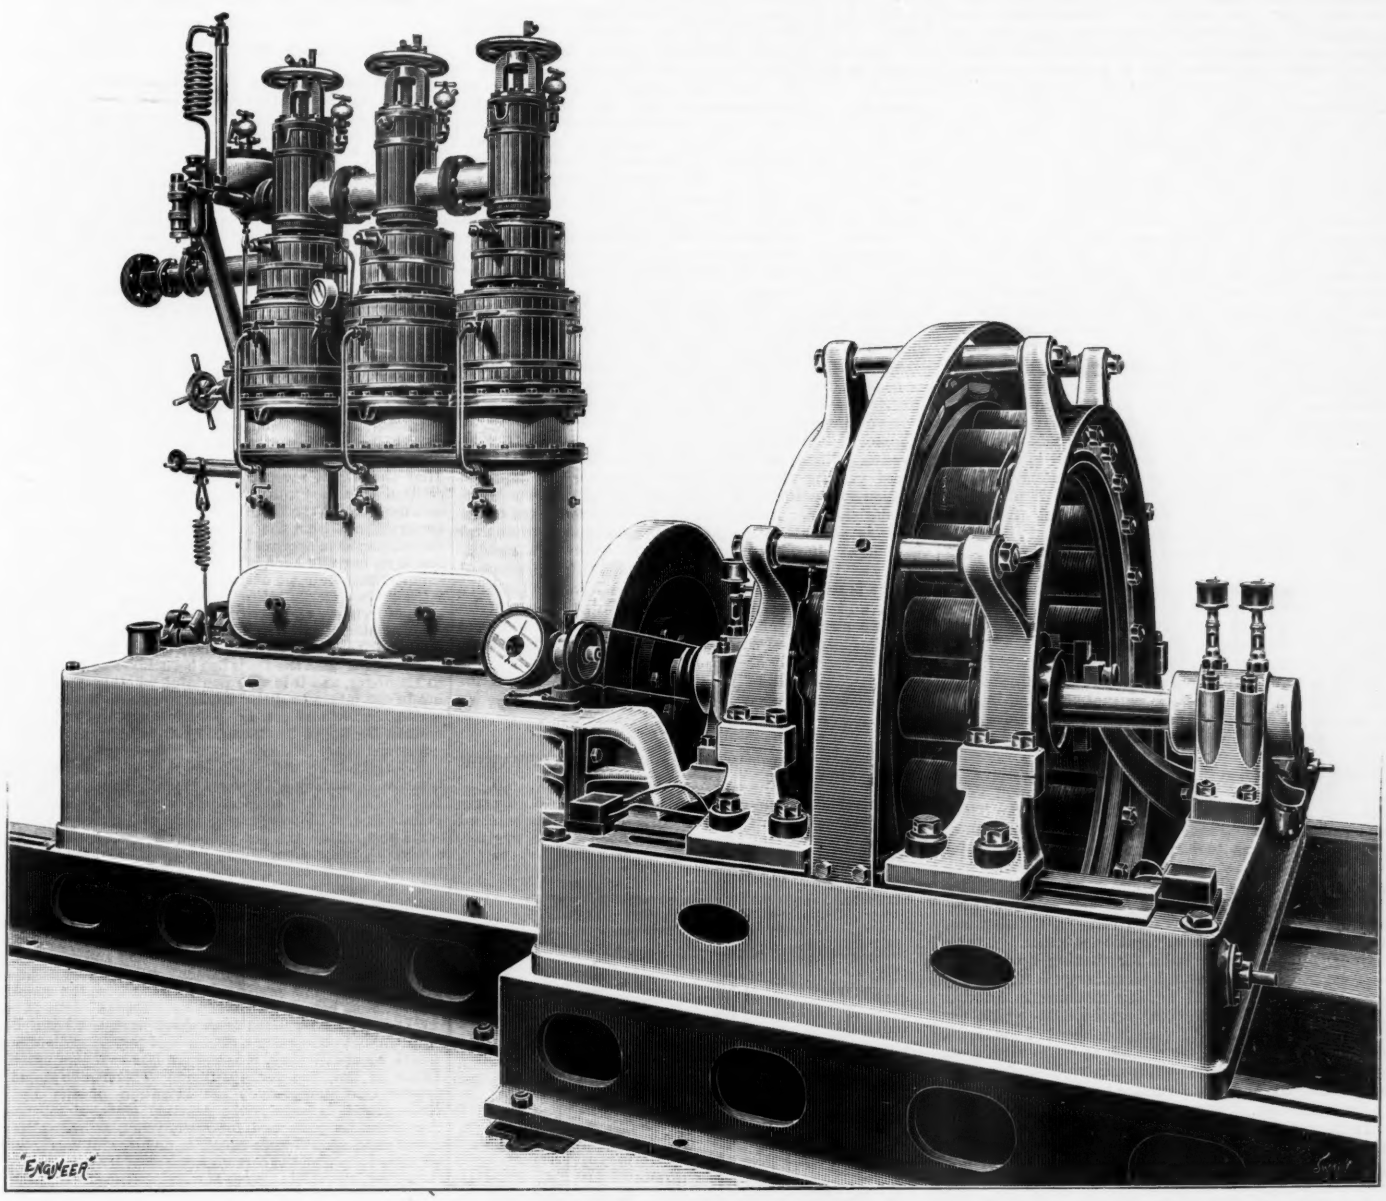
MESSRS. WILLANS AND ROBINSON AND MESSRS. SIEMENS BROS. LONDON, ENGINEERS



divided into two, one branch being 980ft. long by 460ft. wide, and the other 2650ft. by 800ft., with a depth of 30ft. A breakwater is built outside the entrance to protect it from the north and east. The quays will be accessible for ocean steamers drawing over 30ft. As there is no tide in the Sound, and only rarely for a short time ice enough to block the navigation, the harbour will be accessible at any time. The great advantage claimed for Copenhagen as a port and distributing centre is this accessibility at all times. Hamburg is about seventy miles from the mouth of the Elbe, and Bremen, fifty-six miles from the mouth of the Weser. These rivers are only navigable for large vessels during tide time, and in winter are often closed for long periods by ice. The Sound, through which access to Copenhagen is obtained, has only been closed for any considerable period during two winters. From 1881 to 1888 it was open all the winter through, and from 1889 to 1891 was only closed by ice for ten days. In spite of the increased traffic, the stranding and wreck of vessels in Danish waters round the Scaw and through the Sound is decreasing. This is due to better lighting and more efficient pilotage. Still the number of wrecks is very large. Out of the 30,000 vessels which annually pass through the Sound, 210 are stranded, in addition to which nearly 200 vessels are lost at the entrance to the Elbe and the Weser and in the adjacent seas. These accidents generally occur to vessels without pilots. The German authorities claim that the decrease in distance for vessels trading to German ports, and passing through the English Channel, or from any port between Dover and the island of Bornhalm, and using the new Baltic Canal instead of the Scaw route, will be 200 miles. This, at a speed of ten miles an hour, shows a saving of twenty hours. From this, however, has to be deducted about ten hours, caused by the reduced speed at which the vessel will have to pass through the canal. From the ports on the east coast of England north of the Humber, from which a considerable part of the coal for the Baltic is exported, the saving in distance will be very little, while from the Scotch ports the distance by the Scaw will be less than that by the canal. A pamphlet has recently been issued by Mr. C. K. Hausen, of Copenhagen, in which is fully set out the advantages of the port of Copenhagen, as compared with the German free ports, when the North Sea and Baltic Canal is opened, in which he contends that, considering that the charges at Copenhagen will be lower than those of Hamburg; that any saving in distance by the canal to the southern ports of this country, or to transatlantic ports, will be absorbed by the slower rate at which steamers will have to navigate the canal, as compared with the Sound; and that any small saving in time will be more than compensated by the payment of the canal dues; that the access to Copenhagen is at all times safer and less obstructed by ice, and that the draught of water is much greater than to either Hamburg or Bremen; the free port of Copenhagen will be a much more advantageous distributing centre for the transit of goods to the Baltic ports than those to which the new canal will give access.

*Canals.*—In compliance with a memorial from the traders on the Royal Canal of Ireland, the Board of Trade have sent General Hutchinson to hold an inquiry at Dublin, and to make an inspection of the waterway. The matters complained about by the traders are, that the canal is so choked with weeds and mud that the draught of the canal is reduced in summer from 4ft. 6in. to 2ft. 8in.; that the tow-paths are out of order, and dangerous for the horses; that the lay byes and wharfage accommodation have been allowed to deteriorate; and that the accommodation in the Spencer Dock is quite inadequate. At the inquiry at Dublin evidence was given in support of these allegations, and afterwards the inspector proceeded to view the canal.

*American canals.* — The completion of the Manchester Ship Canal has given a stimulus to similar enterprises which have been before the public for some time past in America. Thus both Washington and Baltimore have schemes for connecting those cities by means of a ship canal with New York. It is said that previous to the opening of the Erie Canal, Philadelphia was the first city in the States, and that her commercial supremacy was lost when that great waterway was opened. Since then she has fallen to the third place, and if the proposed canal connecting Baltimore with New York should ever be carried out, Philadelphia would only take the fourth place. At present large steamers take three tides to get out of the long and tortuous river leading from Philadelphia to the sea. It is therefore proposed to construct a ship canal 44 miles long, 11 miles of which would be through the existing Delaware and Raritan Canal, which would have to be enlarged. The proposed width is 90ft. bottom and 150ft. top, with a depth of 20ft., the summit level being 50ft. above the sea. The exit from the canal at the New York end would be near Sandy Hook. The cutting would be principally through low alluvial soil. There would require to be two tidal locks and four lift locks. The estimated cost is about three million pounds. The other scheme is for a canal across the peninsula intervening between the Chesapeake and Delaware Bays, doing away with the present detour of 200 miles round by the capes, and saving from 175 to 200 miles in distance. It is not intended to follow the Chesapeake and Delaware Canal, as it is considered that the relief to the port of Baltimore would be small. Seven different lines of direction have been surveyed for the proposed canal, the distances varying from 106 to 149 miles, the actual cutting varying from 14 to 53 miles, and the estimated cost from about two to ten millions of pounds. Three to five locks would be required. There is also a projected scheme for uniting the Hudson River with the Great Lakes, by a waterway of a size suitable for large vessels, towards which a vote of £10,000 has been granted for the necessary surveys.

## BRISTOL ELECTRIC LIGHT WORKS.

In The Engineer of the 25th of May last we published an account of the Bristol Electric Light Works, with which were given a number of engravings from the working drawings of the station. We now publish above and on page 172 a general view from a photograph of the engine and dynamo-room, and a separate view of one engine and alternator. For a description of the plant now illustrated, we may refer to page 435 of our impression of the 25th May last.

The Federated Institution of Mining Engineers.—The annual general meeting of the members of the Federated Institution of Mining Engineers will be held in Newcastle-upon-Tyne on Wednesday, September 5th, at 12 noon, in the Wood Memorial Hall of the North of England Institute of Mining and Mechanical Engineers, Newcastle-upon-Tyne. Arrangements have been made for visits to collieries on September 6th. The following papers will be read, or taken as read:—"The Stetefeldt Furnace," by Mr. C. A. Stetefeldt; "Walling and Sinking simultaneously with the Galloway Scaffold," by Mr. John Morison; "Timber Bridges and Viaducts," by Mr. Morgan W. Davies; "Explosions in Nova Scotian Coal Mines," by Mr. Edwin Gilpin, jun.; "The Shaw Gas Tester for Detecting the Presence and Percentages of Fire-Damp and Choke-Damp in Coal Mines, &c.," by Mr. Joseph R. Wilson. The following papers, which have been printed in the "Transactions" of the Institute, will be open for discussion:—"Geology of the West Yorkshire Coalfield," by Professor Lupton; "The Transmission of Power by Compressed Air," by Professor Goodman; "The Baum Coal-Washing Machinery," by Mr. F. Baum; "Notes on Coal-Getting by Machinery," by Mr. T. H. Wordsworth; "Photography in Coal Mines," by Mr. H. W. Hughes; "The Coalfields of Sonora, Mexico," by Mr. James Overend; "The Oil Shale Industry of France," by Mr. G. Chesneau; "Spontaneous Combustion in Mines," by Mr. W. S. Gresley; "The Friction of, or the Resistance to, Air-Currents in Mines: Addenda," by Mr. D Murgue.

## BELGIAN MACHINERY AT ANTWERP EXHIBITION.

(*From our Special Commissioner.*)

Messrs. J. Jaspar and Co., of Liége, have one of the most varied sets of exhibits in the Machinery Hall. In the railway material class they show two instruments, to which they give the names of "Dromoscope" and "Dromopétard." The first of these is an apparatus for measuring the speed of trains, and is intended principally to act as a check on drivers, and to prevent them going too quickly at certain parts of the line. It consists of a standard carrying a dial, on either side of which hangs a weight. Fifty yards before the locomotive reaches the instrument the front wheel presses down a lever, connected with the dromoscope by a wire, and thus releases a finger on the dial, which is caused to turn by one of the weights. When the same wheel is level with the instrument it depresses a second lever, which releases the weight on the opposite side of the standard and stops the pointer on the dial. The apparatus is so regulated that the pointer makes one complete revolution when the train is travelling the desired speed. If this speed be exceeded, the dial is so marked that the finger points to the velocity in miles—or kilometres—per hour at which the train passed over the fifty yards between the two levers. This apparatus might be useful in England, but it is hardly possible to conceive a train travelling too quickly on Belgian lines, excepting where there are crossings or points; and in this case the arrangement of wires would have to be modified, and made more complicated. The dromopétard is an appliance intended to give drivers warning of excessive speed. When the velocity is normal, a fog-signal is placed in position to be detonated by the engine; but when it is too great, the wheel, in pressing down a lever, causes a pendulum to swing and draws back the signal out of the way.

At their principal stand, besides a large assortment of perforated plates, steel, iron, brass, copper, and zinc, with every variety of perforation, they show several dynamos and arc lamps. They also exhibit a working model, which they have made for the University of Liége, of a 2000-ton hydraulic press at Messrs. Cockerill's works. It is one-eighth of the natural size, and beautifully executed. But their most interesting exhibit is a Boulengé chronograph, for measuring the velocity of rifle bullets.

Several Belgian firms have very good exhibits of machine tools. Amongst the largest exhibitors of these are Messrs. Ant. Fétu-Defize and Co., of Liége. Their newest tool is a planing machine, for cutting the teeth of bevel wheels. It has two cutters—one for the shoulder and the other for the root of the tooth. Another is a very solidly constructed double boring machine intended chiefly for boring the two ends of locomotive connecting-rods at the same time. They also show a circular saw for metal, a band saw with automatic movement of table in both directions, a large lathe for turning up a pair of wheels, several other lathes, a hydraulic press for railway wagon wheels, and several milling machines. Another exhibit is a grindstone dressing machine, in which the tool travels backwards and forwards in front of the stone. A steam hammer which they exhibit is suspended from steel springs, like carriage springs, by means of leather straps passing through the hammer head. This hammer has a leather brake, at the end of which is a wheel. This wheel acts as a counterbalance, and at the same time the driving strap passes over it, so that by tightening it the blows are made heavier. Messrs. Fétu-Defize also exhibit some Otto gas engines, in which the governor differs from the Otto engines by other manufacturers. It is an ovaloid disc, with balls underneath, and working in a pan. A small brass model of their gas engine runs at 350 revolutions a minute.

Messrs. J. and M. Demoor, of Brussels, show some large milling machines. One of these, vertical, with automatic table, will work 26in. by 12in. and 19in. deep. Another has two cutters, which can either be 10ft. apart or can approach to within 26in. of one another. This tool has two circular tables, which have independent automatic movements in all directions. A horizontal double miller for plummer blocks, &c., has a table which, besides the usual movements, can be made to oscillate. Another horizontal miller will take 28in. wide by 16in. high, for a length of 7ft. 6in. A boring lathe, 26in. above the bed, has ball bearings throughout. The table has all the movements, including the circular, either automatic or by hand.

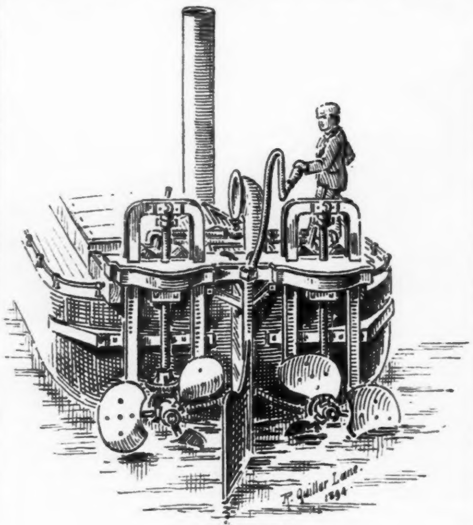
Another lathe which also has ball bearings is a turret lathe, which will turn up to 2ft. diameter by 5ft long.

One of Messrs. Demoor's specialities is their screw-cutting and bolt-making tools. For screw threads, instead of the usual dies, straight cutters are employed. An ordinary stock, for screwing by hand, is replaced by a circular tool-holder with three cutters. Each of these cutters has several grooves, and when once set, they cut the thread at one operation. Larger machines, driven by hand or power, and cutting up to any diameter of screw, are on the same principle. In one which is exhibited with five fixed cutters, there is an automatic stop. This stops the machine directly the bolt head reaches the tool-holder. Whatever the size or shape of the thread, it is cut to its full depth at the first stroke. The other bolt-making tools are intended for producing machine-made bolts when it is required that heads, nuts, &c., should be absolutely identical in shape. In these, one machine turns the bolt to the exact diameter required; or, if necessary, different parts to different diameters, faces the underside of head and the point of the bolt; another machine shapes the sides of the bolt heads and nuts, automatically bringing them to an exact gauge; whilst a third faces the nuts and the tops of the bolt heads. A 40in. circular saw for hot iron, and a band saw, like that shown by Messrs. Fétu-Defize, also form part of this exhibit.

The most interesting appliance shown by Messrs. Demoor is a 25-ton testing machine, the invention of M. Delaloe, of Paris. It can be used for testing tension, compression, or torsion; and as the pressure employed is registered in three separate and independent manners, the probability of accuracy is greatly increased, since the three can be compared continually throughout the trial. The machine, which occupies a space of 7ft. 4½in. by 2ft. 3½in., stands on a cast and wrought iron frame. It consists chiefly of two cylinders, with which are connected the jaws holding the piece to be tested, and a pump or compressor to force the liquid which is used—generally oil—into the front cylinder. This pump is driven by a screw connected with two hand wheels. The smaller of these, which works direct, serves to start the pump, or for returning the compressor after a test. The larger one, which drives the screw of the pump by means of a worm-wheel and pinion, is intended to be used when greater force is needed. Either of these hand wheels can be put into gear as required. On the side of the machine is a steelyard with a sliding weight. This is attached to the piston of the back cylinder, with which, as mentioned above, the jaws holding the piece to be tested are connected; so that, by sliding the weight, the strain may be read on the steelyard. The cylinder is filled with an incompressible liquid, and in communication with it is a pressure guage. As the guage has been graduated from the steelyard, it is not necessary to allow for friction, &c., or to consider them as possible causes of error. The third method of recording the stress is by means of an apparatus similar to a Richards steam-engine indicator. The piston of this is also in connection with the back cylinder, so that it rises with the stress; whilst a cord passing round the barrel carrying the paper is fastened to a point on the piece to be tested, at a determined distance, In testing, the pencil first makes a line which is almost vertical, as the prolongation is at first very slight; but at the elastic limit there is a sudden bend, and the curve gradually flattens, till the point of rupture is reached. The maximum needle on the pressure gauge, and the weight on the steelyard, each show the breaking strain; but the diagram shows how the prolongation has varied with the stress throughout the whole test, and especially at what stress the elastic limit was reached. With slight modifications, the procedure for compression or torsion is the same as when testing for tension.

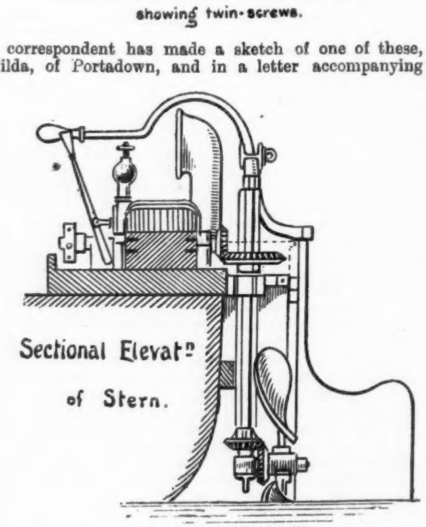
## TWIN-SCREW PROPELLERS WITH ADJUSTABLE IMMERSION.

Under this title we published, on the 10th inst., a paper by Mr. Barcroft giving the results of trials of barges fitted with these screws and driven in some cases by oil engines.



Stern view of "Hilda" of Portadown, showing twin-screws.

A correspondent has made a sketch of one of these, the Hilda, of Portadown, and in a letter accompanying the sketch, which we here reproduce, he says:—"Each screw is driven by a separate engine—a Vosper two-cylinder engine—placed as shown, and driving the vertical shaft by means of bevel gear. The propeller is driven by a pair of mitre wheels, the screw revolving freely on the short horizontal stud shaft fixed to the footstep, as shown in the section, which is not to scale, however. The rest explains itself, I think. The barge is shown 'light,' and the screws very little immersed. When she was loaded the water would, I think, cover the bosses, but probably no more. The man in charge seemed to have her under complete control, and steered by simply making one screw revolve much faster than the other."



## GERMAN STEAM SHIPPING IN SOUTH BRAZIL.

The British Consul at Rio Grande Do Sul, in a recent report on the trade of that State, observes:—"The continued steamship competition by German lines has had disastrous results to British steam shipping to the ports of Porto Alegre, Rio Grande Do Sul, and the South of Brazil, the Germans having succeeded in getting the bulk of the carrying trade of this State—previously British—and the only trade of importance the former had not got into their own hands. The steam trade with South Brazil is one of growing importance, and one which might have been surely held with the same determination and energy, such as was shown by the German companies when they found that British shipowners were apathetic and careless; but, judging by what has occurred here, it looks as if British energy, enterprise, and foresight, were things of the past.

"When the recent revolution compelled the entire Brazilian merchant fleet to remain idle in port, it was felt certain that this coast would in a few weeks be served by a mass of steamers under the British flag, and that they would find an opening into Brazilian trade which would last long after peace had been restored, but this has not been the case. One British steamer came out in competition in 1892, and though a financial success, was not followed by others. After the recent revolution, beyond the entrance into competition of a very mild nature with the German steamers now carrying on the Brazilian coasting trade, of four British steam lighters from the River Plate, no steamers under the British flag have appeared, and although one of an influential line is on her way here, she has been so badly supported by shippers that no more of the same line are likely to follow.

"The two German lines have combined as to agents and rates of freights, and have sent out here four huge lighters, each capable of carrying 600 tons of cargo, and a powerful steam tug to tow them on the lake to and from Porto Alegre. The result is that the trade has been diverted from Liverpool to Hamburg, and it is very doubtful whether that port will not in the future hold the entire Southern Brazilian steam traffic. The decrease in British shipping entering Rio Grande Do Sul in 1893 was 17,199 tons, or 33·82 per cent. under the entry of 1892.

"German trade with Porto Alegre is increasing and British trade is diminishing to some extent, owing to the better facilities afforded by the German steamship companies from Hamburg, and the lower freights by sailing vessels from the same port, which are generally much less than those from Liverpool, ruling from £1 7s. 6d. to £1 15s. per ton for the former, as against £1 15s. to £2 5s. per ton, and 10 per cent. primage, together with an additional 6 to 7 per cent. on these amounts, cost of lighterage, &c., for the latter.

"The trade in wrought iron, and to a great extent in steel, has been diverted from England to Germany in consequence of this. The machinery for a large cotton and wool mill here was recently all got from Germany, though this is probably mainly due to the foreman, by whose advice the machinery was selected, being a German.

"It is to be regretted that there have not been British shipowners to carry out a determined policy, and although it would be uphill work, it is not too late to regain much that has been lost, and perhaps more. This can be stated with greater confidence, since the intention of the Brazilian Government to restrict the coasting trade to the national flag must be postponed for many years, and the Brazilian merchant fleet will have much to do before it can regain the position it held at the commencement of 1893."

Railways in China.—Last summer the railway from Tientsin was carried to a point just inside the Great Wall, and trains now run so far. The engineers are occupied with the section, 100 miles long, between the Great Wall and Chin-chou Fu, an important city on the coast, some distance to the west of Newchwang. This is the most difficult portion of the whole line, and will require two years to complete. As soon as it is finished an extension will be made from Chin-chou to some place near Moukden, and simultaneously a branch line will be constructed between the Moukden neighbourhood and the port of Newchwang. After the completion of these, the next step will be to take the line on from Moukden to Kirin *viâ* Kuanchengtzu, the most important inland market in Manchuria. The annual sum devoted by the Imperial Government to the construction of the line is £400,000. There is a considerable population in the three provinces together, 20,000,000 on a very moderate computation—and many more are ready to join them from Shantung, just across the gulf. The railway will thus not merely aid in bringing down produce, but will carry settlers to the lands where they are wanted."

Performances of White Star Steamers.—The White Star Line steamer Britannic, on her last homeward trip, leaving New York at 7.8 a.m.—12.8 p.m. Greenwhich mean time—on Wednesday, the 1st August, arrived at Queenstown at 9.56 p.m. on Wednesday, the 8th inst., thus occupying 7 days 9 hours 48 minutes on the passage. The Britannic has excelled this on three or four occasions during the twenty years of her running, but having regard to the length of time she has been at work, it is certainly remarkable enough to call for special notice. This was her 207th round voyage. In September, 1890, the Britannic crossed from New York to Queenstown in 7 days 6 hours 55 minutes, and the striking uniformity of her daily runs in both instances is shown by the following comparison of her logs:—

The Britannic reached the Mersey on Thursday afternoon week, shortly after two o'clock, and her mail was being delivered in Liverpool at four o'clock the same afternoon. The same company's steamer Teutonic arrived at New York on Sunday morning at 2.30, having performed the passage in 5 days 20 hours. The Majestic also has made an excellent run homewards. She left New York at 2.20 p.m.—7.20 p.m. Greenwich mean time—on Wednesday, the 8th inst., and arrived at Queenstown at 7.16 on Tuesday night, having crossed in 5 days 23 hours 56 minutes.

## RAILWAY MATTERS.

Engineers are already at work making surveys for the railway which is to be constructed between Samarkand and Tashkend.

It is reported that a railway will be constructed by Northern and English capital from Atlanta to South Brunswick, a place possessing capital shipping facilities, about five miles from Brunswick, Charleston.

The Hungarian Minister of Commerce, according to the *Standard*, has granted a concession for the construction of an underground electric railway in Pesth, which will be two English miles in length, and will pass from Giselaplatz to the Thiergarten. It will be the first electric underground railway in Continental Europe. It is to be opened on the 1st of April, 1896.

It is proposed that the new line to be constructed by the South-Eastern Railway Company, co-operating with the London, Chatham, and Dover Railway Company, should commence by a junction with both systems at Maidstone, thence to Headcorn, Tenterden, and Appledore; there would thus be junctions with the South-Eastern Railway, both at Headcorn and Appledore.

Although it is less than eight years since the first cable car line was established in St. Louis, since that time rapid transit by cable and electricity has been generally adopted, and there are now only two horse-car lines in the city, one of which is soon to be changed into an electric line. During 1893 about fifty miles were added to the truck mileage, £1,000,000 spent in reconstruction and improvements, and 95,180,550 passengers carried.

The Paris, Lyons, and Mediterranean Railway Co. is building forty compound locomotives with "cut-water" shaped shields in front of the boiler, the funnel, dome, cab, &c., all being similarly wedge-shaped. We doubt if much more than excessive ugliness is obtained by the design, our own experiments in England having shown that a train with the front and hind vehicles so shaped showed hardly any decreased resistance, the side resistance or friction being the principal cause of loss of effect.

A correspondent, writing from Forfar concerning the West Highland Railway carriages, says:—"I have nothing but praise for the rolling stock, from a passenger's point of view at least, except in the matter of ventilation. The windows of the corridor coaches are fixed immovably in their frames. The ventilators used do work, but the air supplied to them enters above the windows so far above the part of the compartment occupied by passengers that the effect is inappreciable." Differences of opinion are, however, so great, that what our correspondent thinks inappreciable might be quite sufficient for others.

The Russian Government has lately received applications from several large foreign manufacturing firms for permission to build workshops in Russia for the manufacture of rails and locomotives. The applicants urge that, in view of the present extension of the Russian railway system, Russian factories are no longer in a position to supply the demands of the railway companies, who are therefore frequently compelled to place their orders abroad. The *Railway News* says that owing to the customs tariff at present existing in Russia, the companies have to pay much higher prices for foreign than for home material, and it is represented that the establishment of foreign factories in Russia will obviate this drawback.

Mr. Charles Liddell, the eminent railway engineer, died on the 10th inst. in his 82nd year. He was associated with George Stephenson in the construction of the old North Midland line from Derby to Leeds in 1835. His latest work was the Manchester, Sheffield, and Lincolnshire extension to London. He was the chief engineer of that company's Derbyshire lines from Beighton to Heath—constructed by Messrs. Logan and Hemingway—and from Heath to Annesley, constructed by Messrs. Balding and Yerburgh. Mr. Liddell was connected with others in the construction of the Danube and Black Sea Railway, and the Novara and Lake Orta Railway, and he laid the Varna and Balaclava cables during the Crimean War, and some cables in the Levant. Railway construction was, however, his favourite work.

There are twenty railways working in Colorado, with over 5270 miles of line, at a rateable value of £6,400,000 and employing 12,000 workmen. These railways pass through a district presenting many difficulties not met with in other sections of the country, yet accidents are very rare. The total earnings of the Denver and Rio Grande Railway, the largest system in the State, for 1893, were £1,559,876, a decrease of £284,471, or 15·43 per cent. under those of 1892. According to the British Vice-Consul at Denver, although the earnings of the other lines cannot be obtained, it is safe to say that they suffered from the commercial depression in a similar proportion. During the year the Atchison, Topeka and Santa Fé system, working the Midland Railway in Colorado, the Rio Grande Southern Railway, and the Union Pacific Railway, went into the hands of receivers.

In the year 1892 one rail broke for every seventy-five miles of line in the United Kingdom; or, taking England alone, one rail broke for every sixty-two miles of line. The London and North-Western Railway broke one rail for every 75½ miles; the London and South-Western, one for every 31½; the London, Chatham, and Dover, one for every 17½; and the Metropolitan, one for every five miles of line. *Indian Engineering* says that on the Rajputana Railway one rail broke for every 164 miles of line; on the North-Western, one for every 248 miles; on the Eastern Bengal, one for every 126 miles; and on the O. and R. Railway, one for every sixty-nine miles. On the four Indian railways referred to, the breakages amounted to 4·399 iron and 31·41 steel rails; or, 35·809 steel and iron rails per annum, on a length of about 5500 miles. That is, one rail broke on an average per annum on each 153 miles of line. This compares well with the seventy-five miles average of English railways.

The following interesting details in connection with the Great Western Railway Company's Works were given to a party of members of the British Association on recently visiting the establishment at Swindon. The construction of the locomotive works was commenced in 1842. In 1861 were erected rolling mills for the manufacture of iron rails. From 1875 the quantity of iron rails manufactured was gradually diminished, and the last lot was rolled in 1878. Since then the mills have been used for the manufacture of merchant iron, the average turn-out being from 160 to 200 tons per week. The carriage works were commenced in 1868, and have been enlarged from time to time. In 1873-4 new foundries were built and additions made to the locomotive works; and the total area now occupied by works and yards is 208 acres. Upwards of 300 tons of chairs are cast every week for the permanent way. At the time of the change of gauge, in May, 1892, a few hundred wagons were sent to the Bridgwater workshops, and, with that exception, all the broad gauge rolling stock was sent to Swindon to be converted or broken up. In order to receive it, thirteen miles of additional sidings were laid down. There were 195 broad gauge locomotives, and of these 130 had been so constructed that they were readily convertible to narrow gauge. In July, 1892, when the work of conversion was in full progress, the total number of hands employed in the locomotive department was 5758, and in the carriage, wagon, and stores departments 4157, making a total of 9915. Since the completion of this work some reductions have been made, and the numbers in July, 1894, were: Locomotive department, 5388; the other departments, 3972; total, 9360. In addition there are about 300 men employed in the traffic and permanent way departments at Swindon.

## NOTES AND MEMORANDA.

A number of Government surveyors who have been engaged in a survey of Popocatepetl have reached the summit of the volcano, whose altitude they have fixed at 19,643 Spanish feet above the level of the sea. The circumference of the crater is 14,000ft. An elaborate study is being made of the smoking rents and other phenomena of the volcano.

At a recent meeting of the Paris Academy of Sciences a paper was read on "Direct Autographic Record of the Form of Periodic Currents by means of the Electrochemical Method," by M. P. Janet. A battery of fifteen steel styles, connected with fifteen points of the circuit taken, so that the difference of potential between consecutive points was about four volts, gave traces on prepared paper which indicated the characteristics of the discharge through the circuit.

In their report of the composition and quality of the London water supply for the month ending July 31st, William Crookes, F.R.S., and James Dewar, F.R.S., state that in the report for June they recorded an excess of 0·58in. of rain over the average. July, they say, has been a still wetter month, the rainfall having been 3·27in.—an excess of 0·89in. over the twenty-five years' average of 2·38in. No wonder it seemed to be a wet month when we learn that the rainfall was 37 per cent. more than the average.

A basket for melting out lead joints formed of three pieces of old sheet iron is mentioned in the *Engineering Record*. Two of the pieces, one for each end of the basket, are V-shaped, the inner semicircle fitting around the pipe so that the piece acts like a flange about 10in. larger than the pipe. The third piece of iron is 18in. long and bent to fit the ends, a basket being formed in this way having the shape of the casing of a gate valve. A number of inch holes are punched in the bottom for draught, and handles attached to the sides, through which an iron rod is passed over the main to hold the basket in place when in use. It was intended to employ hot coke in burning out the joints, but owing to the small body of fuel and its consequent rapid cooling, this was found unsatisfactory, and dry wood is used.

A boy eats two ounces of ice. Let us see what is the approximately thermodynamic equivalent of the work he has made his interior do, assuming he takes five minutes to eat it. In melting the ice, taking the latent heat of fusion at 143 units, and the specific heat the same for the colouring and sweeting admixture as for the ice, he will require eighteen units to reduce the ice to water. To raise it in temperature to that of his inside, he will require seven more units, or a total of 25 British thermal units. Taking the mechanical equivalent as 777 foot-pounds, this will be equal to 19,425 foot-pounds. If the boy weighs 100 lb., he will have called upon his stomach to do as much heat work as would, with a machine having unit efficiency, raise him 194ft. high, or a rate of heat extraction equal to nearly an eighth of a horse-power.

In a recent number of the *Comptes Rendus* is a contribution to the study of the structure of steel, by M. F. Osmond. With moderately hard steel, containing 0·45 per cent. of carbon and 0·35 per cent. of manganese, the structure was found to vary gradually in samples all originally heated to 825 deg. C., and quenched in water at 15 deg. C. after cooling to 720 deg., 690 deg., 670 deg., 650 deg., and 640 deg. respectively. Hardening from 640 deg. left the structure almost the same as slow cooling. With hard steel, containing 1·24 per cent. carbon, the variation is more rapid; the temperature of maximum hardening lies very near to that of no hardening. The structure, as studied by polished surfaces, in steel of moderate hardness gives information concerning (1) the maximum temperature of heating, (2) the temperature from which it has been hardened, and (8) the rate of cooling.

Some slag cement experiments made by R. W. Mahon, at the Maryland Steel Company's Works near Baltimore, are reported in a recent issue of the *Journal* of the Franklin Institute, and show unusually good results. The limestone used in the blast furnaces of the company is procured near Baltimore, and is of two varieties, one low and the other rich in magnesia, the former being preferable for cement making. The slags were granulated carefully, and ground so as to pass through a 100-mesh sieve. They were then mixed together, the best combinations having less than 30 per cent. of silica and over 47½ per cent. of lime. To get the best results, to such a mixture was added a quarter of its weight of slacked lime. Briquettes made in this way, and allowed to harden for twenty-eight days in air, or one day in air and twenty-seven in water, broke under a tensile strain of from 210 lb. to 375 lb. per square inch, depending upon the conditions of hardening.

The "Interim Report of the Committee appointed to Inquire into the Proximate Constituents of the Various kinds of Coal," British Association, Oxford, August, 1894, shows that this Committee has started its labours. Coal from Hutton Seam, which is bituminous and used as a gas coal, has been used in the following investigations. Heated with ether it yields a yellow solution, with blue fluoresence. Alcohol, benzene, and petroleum ether dissolve but little from it, the solutions being similar to the ethereal solution. On this coal, acetic anhydride and glacial acetic acid have but little effect as solvents; but a solution of sulphur dioxide in glacial acetic acid, when heated at 100 deg. with the coal in a closed pressure flask, becomes dark in colour and—on the addition of water—yields a light yellow precipitate. The precipitate is soluble in ether, and the solution on evaporation leaves an oily residue. Turpentine heated in a pressure flask with the powdered coal, darkens and acquires a greenish-blue fluoresence. Aniline dissolves an amorphous solid from the coal when heated with it; the solid is precipitated from aniline by means of hydrochloric acid. This solid leaves resinous residues from its alcoholic and benzene solutions, is oxidised by dilute potassium permanganate yielding a dark brown solution, containing potassium carbonate and potassium salts of organic acids. The coal itself also reduces permanganate and yields a dark-coloured solution, containing amongst other things oxalic and other acids.

What is called a new branch of metallurgical science has just been opened up in France, which is likely to have an important influence upon the iron and steel industry in that country. This discovery is due to the researches of the Commission which was formed in 1891 by the French Government, with a view of determining upon some more accurate method of testing constructive material than at that moment existed in France, and to the absence of which was attributed—however groundlessly—the failures of important bridge and other works that had become unpleasantly frequent. A report upon the inquiry of the Commission has just been drawn up by MM. L. Baclé and Debray, who set forth results that are considered by them, and by those who thought the Commission necessary, to be of the greatest value to the metallurgical industry. By the aid of a microscope it is said to be found possible to detect molecular changes in metals, that vary according to the constituents of which they are composed. The changes of appearance are of almost infinite variety; and each of these appearances are said to show accurately the presence of certain elements, some of which may be in such small quantities as to be undetected by chemical analysis. For instance, the presence of phosphorus in tin bronze causes a characteristic granular appearance that cannot be confounded with any other constituent, and the smallest quantity of aluminium will produce a distinct change in the metal. The value of this new science of "Metallography"—as it is called—lies particularly in the fact that it will allow of the most delicate alloys being made, and it opens up a very wide field for metallurgical research; but its value in bridge construction seems remote, and does not point the way to design bridges that will stand with insufficient material, nor to avoid the necessity for experience in the proper disposition of material.

## MISCELLANEA.

The Gohna Lake rose 30ft. 2in. last week, and is now within 27ft. of the top of the dam.

Garbage treatment works at New Orleans have recently been started. The garbage is first steamed and then exposed to naphtha vapour, as at the cities of Providence and Cincinnati.

The Greenwich Hospital Pensions of £50 a-year for Chief Engineers, rendered vacant by the deaths of Fleet Engineer W. B. Minhinnick and E. O. Crichton, have been awarded to Fleet Engineers B. F. Pine and C. M. Collins, R.N.

A German tank steamer named the Heligoland recently sailed from Philadelphia to Hamburg, with a cargo of 1,200,000 gallons of naphtha in bulk. This is the first time that naphtha has ever been shipped in bulk across the Atlantic.

The tender of Messrs. John Penn and Sons, engineers, of Greenwich, for the construction of the propelling machinery, &c., of the new first-class battleship Illustrious, shortly to be laid at Chatham Dockyard, has been accepted by the Admiralty.

The first-class battleship Resolution, which has just returned to Sheerness from the naval manœuvres, is docked at Chatham for the purpose of being fitted with bilge-keels. The Royal Sovereign and the Empress of India, the two flagships of the Channel Squadron, are also to be fitted with bilge-keels.

There is a National Association of Master Bakers and Confectioners, but this is apparently not able to cover all the ground, and the London Master Bakers' Protection Society is discussing the project of standard samples of foreign flour, and at the last meeting of the Protection Committee a report was received, from which the following is a passage:—"It was necessary to fix a standard by which they knew they would get the same quality, be it higher or lower, as they were getting to-day, as fixed by the standard to be adopted."

A recent explosion, with a loss of seven lives, at Corfu, is stated to have been caused by a torpedo, which is believed to have escaped from the British Mediterranean Fleet, and to have been picked up and sold to a Jewish marine store dealer. We think this is hardly probable, as torpedoes under no circumstances carry their war-heads during practice. It might possibly have been a mine which had missed fire, but which, if it had been left in this dangerous condition, would point to most exceptional carelessness on the part of the naval officers engaged.

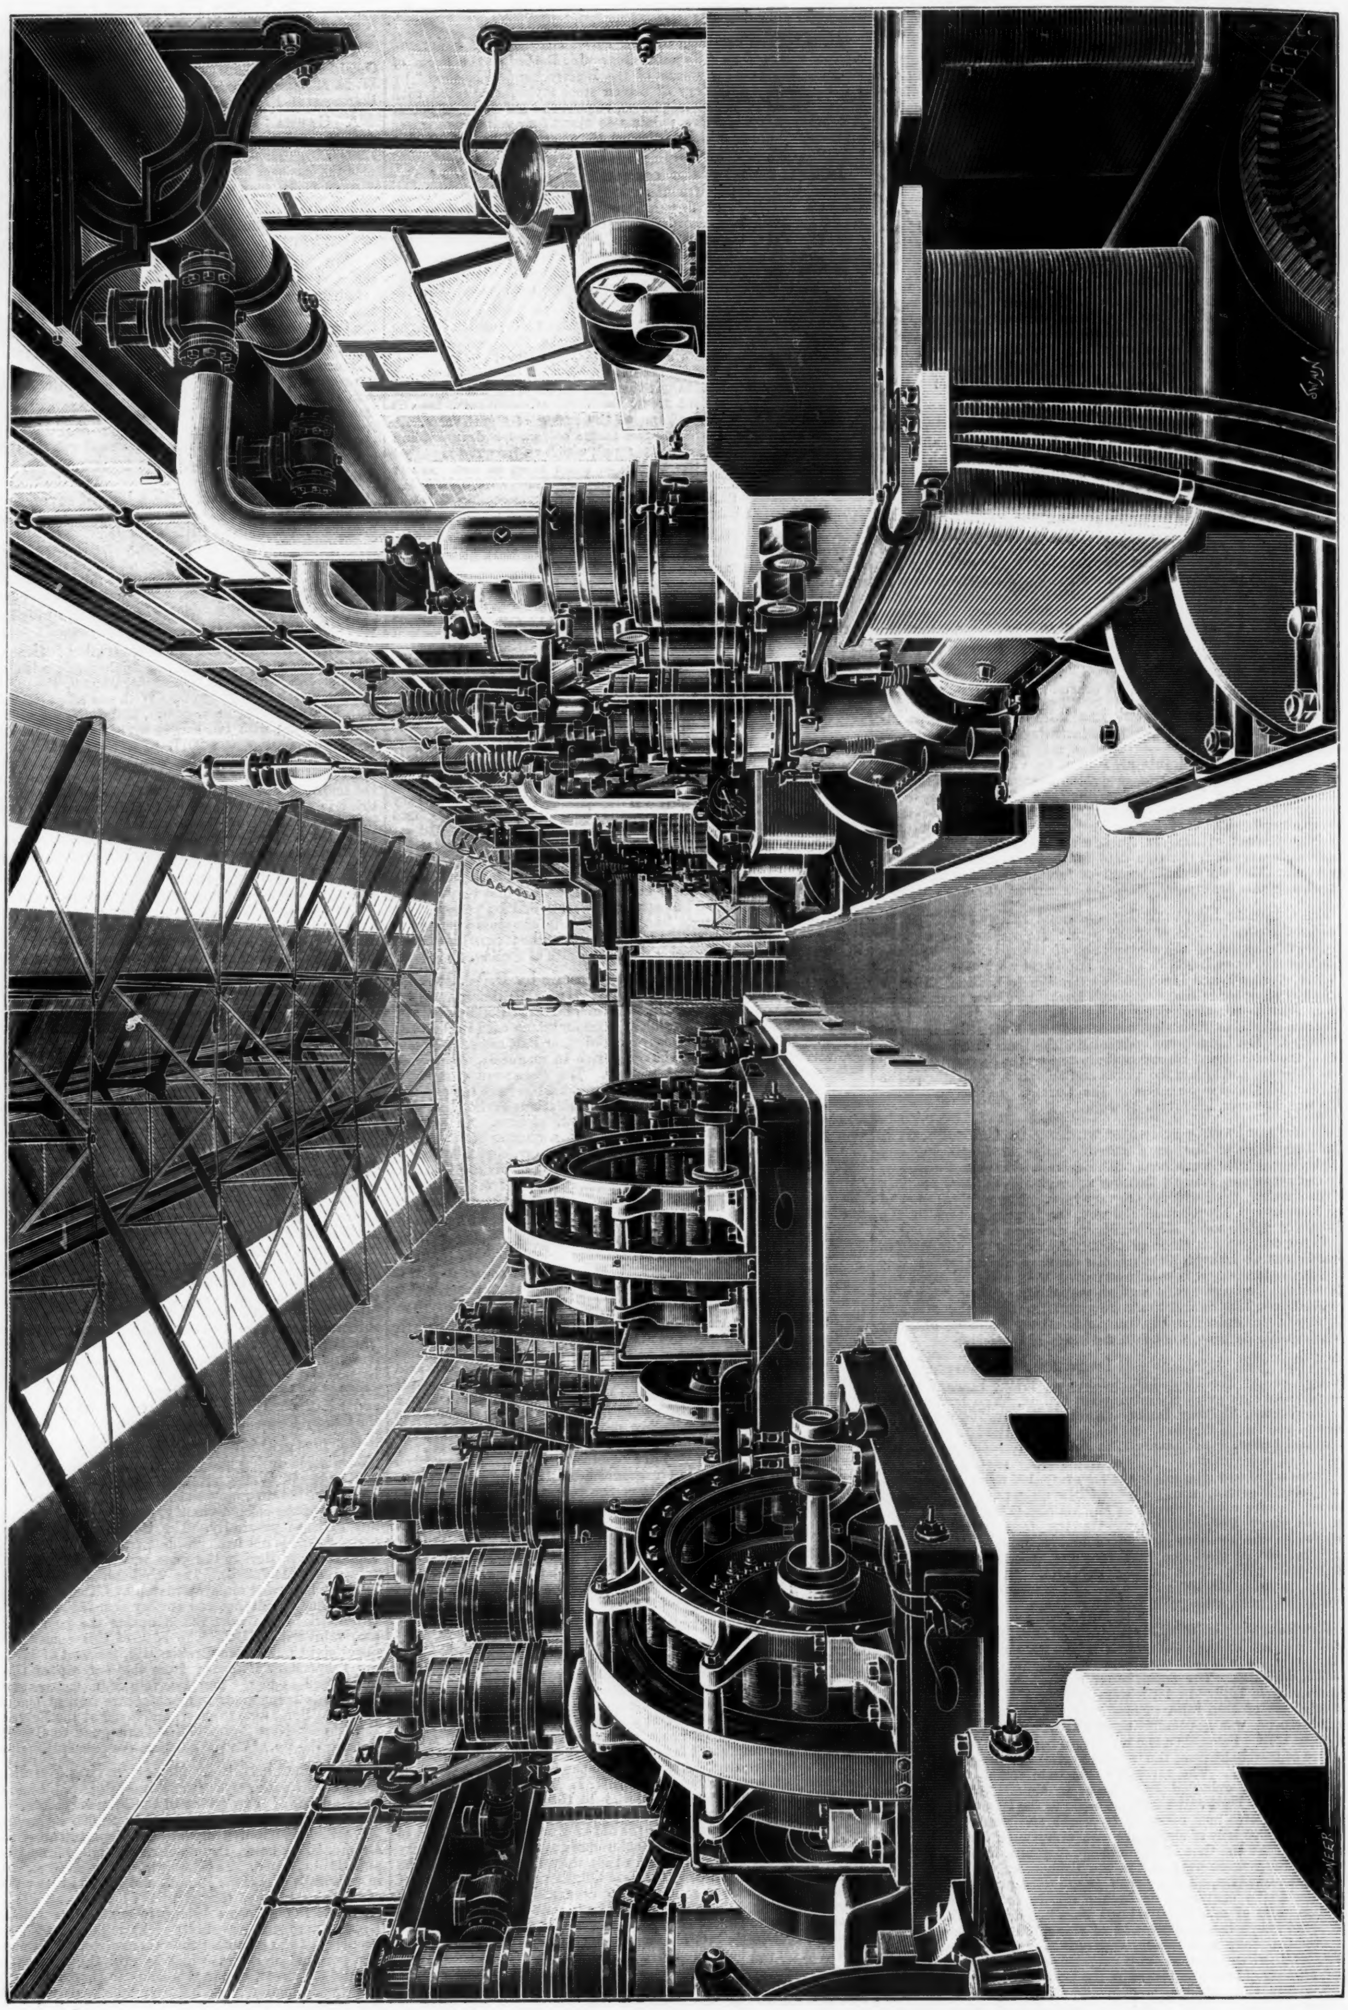
The official report of the trial of the U.S. cruiser Minneapolis gives figures of the trials made with one, two, and three screws. Each trial lasted eight hours, the speed throughout being a little under 10 knots. With one screw it was 9·73 knots, with 1920 indicated horse-power, and a consumption of 4630 lb. of coal per hour; with two screws the speed was 9·71 knots, the indicated horse-power was 2017, with a consumption of 4773 lb. of coal per hour. The third trial, with all the three screws, was made at a speed of 11·6 knots; the indicated horse-power was 2491, and the hourly coal consumption 6411 lb. An interesting point which this trial shows is that while it took something more than 2500 indicated horse-power to obtain 11·6 knots, it took more than eight times this power to give the ship a speed of 23·07 knots, showing thereby the great economy effected in low-speed running.

The East River tunnel built by the East River Gas Company has been completed, having been commenced in 1892. "The tunnel," *Engineering News* says, "is 2516·4ft. long, 8½ft. high by 10ft. wide, runs under Blackwell's Island, and comes out on the New York side at Seventy-first Street. The top of the tunnel under the channel on the New York side at the point of nearest approach to the bottom of the river is 40·93ft. below the river bottom; while under the channel on the Brooklyn side, the nearest approach of the top of the tunnel to the river bed is 82·33ft. The depth of water in the channel on the New York side is 65ft., and in the channel on the Brooklyn side is 30ft. The shafts are each 9 ft. square, the one on the New York shore being 135ft. deep, and that at Ravenswood being 147ft. deep. The tunnel under Blackwell's Island goes through solid rock. Under the river it is lined with iron plates surrounded by liquid concrete, which makes a solid bed. It will be used to convey gas to this city from gasworks on Long Island.

The annual report of Mr. George F. Lyster, engineer of the Mersey Docks and Harbour Board, which has just been issued, gives some particulars about the dredging operations at the bar of the Queen's Channel at the mouth of the Mersey. The report is interesting, both on account of the improvement effected at the bar and of the work performed by the great dredger Brancker. The total quantity of sand removed in twelve months was 4,407,150 tons, making a total of 6,845,860 tons removed since the beginning of operations. The depth of water in a buoyed channel 1000ft. wide is not less than 20ft. in any part at extreme low water of spring tides, and outside the buoys there is also considerable depth, 19ft. at one side and at least 15ft. on the other. The Brancker's size enables her to work during weather in which it would be impossible for smaller vessels to work. She has filled herself with sand in 35 minutes. In one period of 24 hours she received no less than 39,000 tons of sand, and in a week of five and a-half days 183,000 tons. Other dredgers have operated in the Crosby Channel.

So far nothing tangible has yet resulted from the efforts made during late years to establish the iron-making industry in New South Wales, although attention has from time to time been directed to many natural advantages possessed by several districts of the colony, namely, deposits of iron ore, with coal and flux in close proximity. The iron made in the colony at the present time is not from ore, but from scrap, and the quantity so manufactured during the year was 2190 tons 11 cwt. 1 qr. 4 lb., valued at £14,786 6s. The Eskbank Iron Works, where this industry is carried on, are situated at Lithgow, on the western side of the Blue Mountains, and employ about 150 men. In the Broken Hill district there were raised during the year 1051 tons of iron ore, valued at £1198. The bulk of this comes from Balaclava, about eight miles from Broken Hill, the rest of it being taken by the Proprietary Company from the outcrop of the lode. It is solely used as flux. The *American Manufacturer* says that a fresh attempt is being made to manufacture iron at Onehunga, in New Zealand. Some men formerly employed at the Eskbank Ironworks, at Lithgow, New South Wales, have gone to Onehunga, and are starting the works on the co-operative principle.

The French Silk Machine-weaving Syndicate, according to the *Moniteur Officiel de Commerce*, has published some interesting statistics of the working of the French machine loom industry. This working includes no less than 25,008 looms divided among 209 mills, distributed among ten departments—Ain, Ardèsche, Drôme, Isère, Loire, Puy-de-Dôme, Rhone, Sasne-et-Loire, Savoie, and Haute Savoie. The department of the Isère, which abounds in waterfalls, has alone 73 mills and 12,438 looms; the department of the Rhone comes second with 51 mills and 3778 looms. 141 mills and 15,041 looms belong to contractors who work for the Lyons manufacturers. Sixty-eight mills and 9967 looms are the property of the manufacturers themselves. This method of direct and personal working, which is still the exception, is gaining ground each year, and in this manner there is being accomplished the transformation of an industry which, only twenty years ago, was carried on at home in small workshops, both in the towns and country districts. The number of hand-weavers, which was from 50,000 to 60,000 at Lyons under the Restoration, scarcely reaches 10,000 at the present time; and, further, the weavers find little to do, as they are unable to stand against the progress of machine weaving.



THE BRISTOL ELECTRIC LIGHT SUPPLY WORKS—ENGINES AND MACHINE

MR. W. H. PREECE, F.R.S., AND MR. GISBERT KAPP, M. INST. C.E., ENGINEERS; MESSRS. WILLANS AND ROBINSON AND MESSRS. SIEMENS BROS., CONSTRUCTORS

## TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

N. C.—*The inside wheel in almost all cases.*

A.M.I.C.E.—*We believe that the drawings you want have already been published in more than one journal dealing with yachting.*

W. C. (Battersea).—*The engine would not be reversed simply by running it with the steam cut off. Engines have been reversed by the drivers when running at higher speeds than you mention.*

T. M. (Alleghany).—*There is no reason why the marine engine should not work as economically on land as in the ship. On land it might always have dry steam, which would give it an advantage as compared with the wet steam it might often get at sea.*

Cotswold.—*You would have very great difficulty in getting an appointment on the big liners, not having been trained in marine work. Examination will not help—that would come after. You could, however, enter the Navy by passing the examinations of the candidates for entry as probationary assistant-engineers. See advertisement in our issue of the 27th ult.*

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

| | |
|---|---|
| *Half-yearly (including double number)* | £0 14s. 6d. |
| *Yearly (including two double numbers)* | £1 9s. 0d. |

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

| | |
|---|---|
| Thin Paper Copies— | |
| *Half-yearly* | £0 18s. 0d. |
| *Yearly* | £1 16s. 0d. |
| Thick Paper Copies— | |
| *Half-yearly* | £1 0s. 3d. |
| *Yearly* | £2 0s. 6d. |

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

# THE ENGINEER.

*AUGUST* 24, 1894.

## RAILWAY TRAFFIC AND REVENUE.

The Railway Returns for 1893, presented to Parliament by the Board of Trade, and issued at the close of last week, present some striking features, reflecting the perturbations of labour and trade in the United Kingdom. The gross receipts for the year amount to £80,632,000, or £1,460,000 less than in 1892. If we eliminate the miscellaneous class of receipts, which of themselves show an increase, and confine our attention to the actual income from traffic, we find that the falling off is as much as £1,685,000. In the receipts from the conveyance of passengers there is an increase of nearly £187,000. It is therefore in the goods traffic that we find the cause of the deficiency, the receipts from that source being diminished by £1,872,000. The income from the goods traffic source has never been so low since 1888, whereas the receipts from the passengers have never been so high. The revenue from the former source last year was under 51 per cent. of the total receipts, a lower proportion than is recorded in any year since 1857. On the other hand, the receipts from passengers were in a higher proportion to the total last year than at any date subsequent to 1867. The working expenses in 1893 were £45,695,000, or a trifle less than in 1892, and taking 57 per cent. of the total receipts, a higher proportion than in any previous year. The net receipts were in the proportion of 3·60 per cent. to the total paid-up capital, a lower ratio than appears at any date since 1860, when this kind of reckoning was first available. On no occasion do we find the ratio reaching 5 per cent., the nearest approach being 4·74 per cent. in 1872. The total paid-up capital exceeds £971,000,000. Less than £35,000,000 was the amount which the capitalist received on this enormous investment last year. Above £53,000,000 of ordinary capital on constructed lines yielded no dividend whatever, whereas in 1892 the capital thus without return was barely £43,000,000. It is also to be observed that the capital per mile of line open was higher last year than at any previous date, the amount being £47,000. Only four years earlier it was £44,000. The traffic receipts per mile of line open were less than in any of the three years immediately preceding, and the amount per train mile was lower than at any previous date, though the difference compared with 1892 was only a farthing. The amount is now very nearly threepence under five shillings, whereas in 1856 it was only three farthings under six shillings, and as late as 1874 was 5s. 8d. The miscellaneous receipts, including proceeds from rents, tolls, navigation, and steamboats, show a continual increase, amounting last year to 4·70 per cent. of the total receipts.

The particulars as to the number of passengers carried during the year introduce us to the interesting problem as to the progressive variation among the classes. On the whole there was an increase of 8,741,664 in the number carried, exclusive of season ticket holders. In the first class there was a decrease of 553,342, and in the second a decrease of 1,858,173, making a total decline in these two classes of 2,411,515. Against this we have to put an increase of 11,153,179 in the third class. The enormous preponderance of the third class appears when we take the actual number carried. Thus, the first class were not much more than 30,000,000, the second class a little under 60,000,000, and the third class 783,000,000. If we go back a step, and compare 1892 with 1891, some facts of importance will appear. Whereas last year there was an increase of above 11,000,000 in the third-class journeys, in 1892 the increase was more than 20,000,000. The first-class passengers underwent some increase in 1892, but the loss in 1893 more than neutralised this advance. In the second-class there has been a continuous decline since 1891, the entire loss being 3,388,000. By way of summary, we may state that the increase of all classes taken together in 1892 was a little under 19,000,000, and that of the third-class alone more than 20,000,000. In 1893 the increase of all classes was 8,741,000, and of the third-class above 11,000,000. Coming to the pecuniary results, we find a decline in the receipts from the first and second class, and an increase in the third class, as also in respect to season tickets. An increase of rather more than £64,000 appears on the whole. Adding on the charges for excess luggage, parcels, and the receipts for the conveyance of carriages, horses, and dogs, together with nearly a million for the mails, the entire revenue from the passenger traffic becomes £35,849,449, being an increase of nearly £187,000. In the receipts from passengers, the holders of season tickets account for as much as £2,583,000. This shows an advance on the previous year. But the third class furnish more than two-thirds of the passenger revenue, apart from the mails and other miscellaneous items.

We have already remarked the decline in the receipts from the goods traffic. Out of the total decrease of 1,872,000, minerals are accountable for £1,425,000. In the carriage of merchandise there is a decline, and in live stock some increase. In Scotland there was an increase for the carriage of minerals, but in England the falling-off from this source was large, being as much as £1,479,000. With respect to the working expenditure of the lines, amounting to nearly £46,000,000, what are termed traffic expenses absorbed more than £14,000,000, while the cost of locomotive power exceeded £12,000,000. The maintenance of way and works took nearly £7,500,000, repairs and renewals of carriages and wagons £3,900,000, and general charges nearly £2,000,000. Rates and taxes continued to go up, and rose to £2,587,796. The number of miles travelled by the trains was nearly 323,000,000, equal to three times the distance of the earth from the sun, with more than 40,000,000 of miles to spare.

It is worth while looking back to see how this wonderful system of locomotion has grown. The length of line open for traffic at the end of last year was 20,646 miles. At the close of 1853, the length was 7686 miles. Accordingly there has a been growth of very nearly 13,000 miles in the space of forty years. The average has thus been 324 miles per annum, and it happens that the increase last year was 321 miles. The amount of capital paid up, per mile of line open, showed a tendency to decrease down to the close of 1870, at which date it had a lower proportion than that of seventeen years earlier, being little more than £34,000, per mile in comparison with £35,523. After 1870 the proportion rapidly rose, until now we find it just over £47,000, the highest figure yet on record. The gross traffic receipts per mile of line open have increased by more than one-half during the forty years from 1853, although the traffic receipts per train mile are now lower than in any previous year. In the same period the receipts from the passenger traffic have fallen from a proportion of one-half the total to less than 45 per cent., though this was higher than for the previous quarter of a century. The total traffic receipts in 1853 were singularly small, being only a little over £18,000,000, or more than £2,000,000 under the receipts a year later. We now witness a fluctuation in a contrary direction; last year showing a great falling off compared with the year preceding. But there is no doubt better times are coming, and there appears to have been considerable improvement during the past half year. Working expenses seem destined to increase, partly owing to the intervention of the Board of Trade in the matter of hours. The growing burden of rates and taxes is the subject of general complaint, the chairman of the Great Western Company denouncing it as "a horribly increasing expenditure." The chairman of the Great Northern has remarked that—during the last half year—the rates and taxes imposed on the principal railway companies considerably exceeded a million sterling, being an increase of £100,000 over the corresponding period of 1893. In the payment of Government duty the companies are, on the whole, effecting a reduction; apparently by the expedient of charging Parliamentary fares for third-class passengers. The large increase of the third class assists this measure of economy, and must tend to bring about other changes in due course. In many ways the railway system of the United Kingdom has been so modified as to make it widely different from what it was forty years ago, though that length of time extends scarcely so far back as the date of the Great Exhibition.

## OIL ENGINES.

Although the competitive trials recently carried out at Cambridge did not bring to light any essentially new form of oil motor, yet several engines which were only known as to details of construction by the makers, were not only exhibited, but ran through whole or part of the trials; and these engines were, with but one exception, made on the principle of direct conversion of the oil into a gas on its way to or in the cylinder. Great strides have been made in a few months towards the construction of a satisfactory and economical oil engine, and except in one or two cases simplicity has not been overlooked in the endeavour to produce an engine which will give good results, and not be a copy of other engines. Several different ways of arriving at a similar result were shown, but the difference was more apparent than real; one or two essentials were traceable throughout the changes of form of details which tended to hide them.

We are probably destined to see in a comparatively short time a great development in the construction and use of the oil engine, and the rapid progress of the past year or so warrants the belief that another year will witness equally great strides. The oil engine offers so many advantages for small powers and for portable and traction purposes, that even an increase in the price of oil will not much decrease its rapidly extending application. The fact that it needs no boiler, no fire, no gas holders, and very little water, and that its fuel can be bought everywhere, must make it the future motor for very many purposes, not excepting launches. The objections with respect to smell will gradually pass away with the improvements which will make the engine as clean as a corporation water works pumping engine, and as free from offensive smell.

Separating the engines as exhibited in the trial shed, into two main classes—namely, those which had and those which had not separate or independent vaporisers with vaporiser lamps—we have two classes which seem to be widely different, and which, in details of construction, are so, but which, in working, are not so. The simplest of all systems is, of course, that under which the heat of combustion of one working charge provides the heat for vaporising the oil for the next, and, when supplemented by the heat mechanically produced by the compression of the charge, fires it. Simplicity, it would seem, could go no further; and for economy, no better means could be imagined. Remarkably good results are achieved by the engine which works on this system, and one feels that it ought, and perhaps may, yet be the means of obtaining the greatest economy. At present, however, equally good or better results in this respect are obtained from engines which depend for their working on a distinct and separate oil-burning lamp for heating the vaporiser and ignition tube, or, in some cases, for heating the latter only. Some of the lamps used for this purpose consumed a quantity of oil which is small compared with the total, but even so it is a separate quantity which the first-mentioned system does not use at all. Now not only does the engine which employs the lamp use rather less oil per brake-horse power, but it does this with less oil in its cylinder by the quantity the lamp consumes. Further than this, it will be observed that the heat which is generated by this lamp, and only partly taken up by the vaporiser and ignition tube, passes away without any possibility of contributing to the heat converted into work in the cylinder. The question arises, How is it that the system by which the combustion of the whole of the oil used takes place in the cylinder, the presumably best possible condition for an internal combustion engine, does not secure, as yet carried out, the most economical results? The efficiency of the engine ought, one would say, to be higher by an amount somewhat greater than the entropy of the lamp oil and its vapour. Why is it not? If the oil were used with different kinds of burners to heat water in a steam boiler, we could understand differences dependent on the construction of the boiler and of the burners; but here we have the whole heat of combustion of the fuel used, absolutely confined within the walls of the working cylinder of the engine, and yet the efficiency of such an engine is inferior, or no better than that in which a not inconsiderable part of the heat of combustion of the fuel used must be lost.

We can imagine that a first consideration of this question would lead to the remark that the heat required for raising the temperature of the oil, and for evaporising it, is the same or as great in the simple engine as in the independent vaporiser engine, and that the entropy of the subsequently compressed charge of mixed working gases is the same. That, in fact, whether the entropy acquired during evaporation is due to heat supplied within the cylinder by combustion therein, or to heat supplied to a vaporiser by external combustion, its value is the same. This, however, only partly states the case, for apart from the less efficient use of the oil which is burned outside the cylinder, the engine in which the oil is heated and vaporised in this cylinder, merely loses or imparts so much less heat to the jacket cooling water, or may be supposed to do so.

The case is further modified in those engines which employ an external lamp only to maintain the incandescence of the ignition tube, the heat required to raise the temperature of the oil and to vaporise it being supplied by the working cylinder itself. The oil for vaporisation is contained in a jacket surrounding the combustion chamber. In this case almost the whole of the heat due to the combustion of the oil consumed in the lamp might be expected to appear as an excess over that used in the lampless engine, but it is not so. The question then arises, What is likely to be the difference between the entropy-temperature diagram of oil, gas, and air, for an engine in which the whole entropy change takes place in the cylinder, and that in which the same change takes place partly in the cylinder and partly in a separate apparatus, and in which the conditions are affected by a water jacket? The difference might be expected to be as great as it would be between two gas engines, one of which is supplied with gas in the ordinary way, and the other with gas distilled from coal in the working cylinder or chamber directly connected with and open thereto, by heat otherwise passed away in the jacket water and the exhaust.

In the simple engine vaporisation takes place under conditions which have not been included in any thermodynamic considerations yet published, simply because the conditions are new. In it entropy is acquired by the substance used, partly under conditions of constant pressure, and partly under conditions which are neither those of constant pressure nor constant volume. The resulting effect may be evaporisation under conditions which are similar to those of constant volume vaporisation, the effect of compression being merely a more rapid rise in pressure by accumulation. Instead of external work of vaporisation under constant pressure in the ordinary sense, there is vaporisation under constant volume conditions, with external work done upon the substance. With the influence of the water jacket always at work the entropy change during compression may be nil. It is not likely that the report of the Cambridge trials can afford much help on these questions. The figures with regard to the relative entropy change in the jacket water of the different engines could only be of use with oil measurements of great accuracy. From these and the indicator diagrams it may be possible to make some guesses as to cause of the highly economical results obtained by the independent vaporiser engines, and their great similarity in this respect, or even superiority over the simple engine, which might be called the internal entropy engine.

There are claimed for the independent vaporiser several advantages which relate to the working of the engines under varying conditions, and also to the easy determination of the period of ignition apart from other adjustments. In practice there may sometimes be advantages in this respect, but they were not called into play at the Cambridge trials. The simple engine to which we have alluded was represented only in the Hornsby-Akroyd engine, although the action on simple lines was shown by Messrs. Clarke, Chapman, and Co., one of whose engines was run for a considerable time without any separate means of ignition, the electric spark igniter being cut out. In this engine vaporisation is effected by exhaust heat, and is, of course, dependent on and affected by exhaust heat changes. The separately heated vaporiser and ignition tube have advantages where a very variable load has to be carried, because it is possible to reduce consumption by frequent misses which could not be permitted with the internal entropy engine. With the latter it may become necessary to start the vaporiser when a load varies much or falls for a considerable time below a minimum, but as against this it may be noted that the other engines burn a lamp not only at starting but always. The oil engine in its several forms presents many features of great thermodynamic interest, and the point to which we have referred is one of the first to which attention may be usefully directed, unless it be made second to the invention of better, cleaner, and simpler, if not quicker means of starting than are now available.

◆

### THE YORKSHRE COAL TRADE, THE SCOTCH STRIKE, AND THE PIT LADS' STRIKE.

One of the most remarkable circumstances in connection with the Scotch miners' strike is the little effect that it has had on the coal trade of the country. Some of the pits in Durham and Northumberland have been beneficially affected, but although the struggle has lasted nine weeks, it has had very little effect on the Yorkshire coal trade. This is an interesting fact for the Scotch miners and their advisers to consider. During the last fortnight many collieries in Yorkshire and Derbyshire have been set down owing to the revolt of the surface men and pit lads, and one of the largest in South Yorkshire is still idle. The local feast which has been celebrated during the week has caused the collieries within a radius of four or five miles to be stopped for two or three days, whilst Monk Bretton has suspended operations for a full week. Notwithstanding all these curtailed influences, there is plenty of coal stacked at the pits and in wagons awaiting orders. Although the mischief done has been great, the coalowners of the county, which met at Sheffield on Tuesday, failed to decide the question, and the miners' officials have made arrangements for a meeting of the Joint Committee of coalowners and men's representatives to be held at Sheffield to-day Friday, in order, if possible, to come to some definite arrangement respecting the rate of wages to be paid to the surface men and pit lads. These lads are the pony drivers and banksmen of the Yorkshire collieries, and they have risen in revolt against a 10 per cent. reduction. There is more reason for their strike than in many of the ruptures caused by their seniors in the coalfield. When the miners' leaders, by a series of strategical manœuvres well timed and cleverly carried out, succeeded in enforcing 40 per cent. advances, it was only the underground workers who participated in the sudden flush of prosperity. Now that it is necessary under the two years' truce to take 10 per cent. off, those who did not get it—the boys and the banksmen—not unnaturally ask, Why should we be required to give that which we have not got? The difficulty ought not to be of long duration. The meeting of the Conciliation Board to-day should settle it. Coalowners no doubt interpret the 10 per cent. reduction in wages as applying to all classes of workers. In fact. the miners' leaders interpreted the agreement in that light as well, so they issued an order that it was to be enforced all round. The pit lads and the banksmen, however, have had the courage to say "No; we got none of your 40 per cent. advances, and therefore it is not just to call upon us to make any reduction." The lads have the sympathy of the public on their side. The general feeling is that those who did not get the spoils cannot be expected to give any. If the 10 per cent. reduction is too little unless it is conceded by every class of workers, it is clear that sufficient should have been demanded to meet the emergency, but it should have been demanded from those who got the increased pay, not from those who got none. It is not the first time that collieries have been set down through the action of pit boys, and although it is an amusing instance of "the tail wagging the head," this time the tail wags with fair cause.

### COALS AND GAS MANUFACTURE.

The effect of the alteration in the condition of the coal trade and in the price of coals must be marked on the gas manufacture, though the effect is not yet fully evident. Some years ago we traced at length in The Engineer the course of the fall in the price of coals on gas manufacture in the case of a company close to the great coalfield of Durham; and it may be now interesting to glance at its statistics again. In the year ending with June, the company carbonised some 29,665 tons of coal. The total quantity of gas sold is not stated — part being for public lighting; but 240,040,900 cubic feet were sold apart from that contracted for, and judging by the receipts for the gas contracted for, the production was considerably in excess of the 10,000 cubic feet per ton, which once used to be aimed at, but is now generally surpassed. The cost of the coals deposited at the works is, of course, increased, and it now averages about 8s. per ton, but there is included a small quantity of Cannel coal for enriching purposes. It is noticeable that the yield of coke for the year was a little over 18,700 tons, and as over 4,700 tons were used in the manufacture, and there was a slight addition to the stock, the 13,500 tons or thereabouts sold for £5662 after the cost of labour, cartage, &c., was deducted, represents a fair price for the residual. Generally it may be said that concurrently with the rise in the price of the coals used in the manufacture of gas, there is some improvement in the receipts from the sale of residuals, though not always to a concurrent extent. It would appear that even on the verge of the chief of the gas coalfields, the cost of the coal is increasing to the gas companies, but there will be the counterbalance of an enlarging production and of better results from the residuals. Year by year an increase in the number of the gas stoves that are let out on hire, and thus the revenue is being derived not only from the gas used as an illuminant, but also from that used for purposes of heat and power. In the case of the company we have referred to, the rental of gas meters for the year was £1260, whilst that from gas stoves has already risen to £352, or more than a fourth of that of the meters, so that the enlarging use of gas for this method of consumption is now becoming very marked. And it is to be noticed that it is in very large degree a day consumption, so that it is doubly a benefit, giving a demand that occurs at a time when that for purposes of illumination is at its lowest. It would thus seem that though the gas manufacture has to pay more for its raw material, there is the opening out of the additional sources of use and of revenue that will in the end more than make up for any loss that follows from the use of electricity for the purposes of artificial light, and that will give an even better revenue to the companies engaged in the manufacture.

### TORPEDO-BOAT AND SHIPBUILDING IN FRANCE.

The new sea-going torpedo boat, Le Chevalier, constructed by M. Normand, of Havre, has lately been tried with excellent results, and its rate of speed was higher than any hitherto attained in France. The boat has a length over all of 44 metres, and its beam at the water-line is 4·38 metres, while its displacement is 118 tons. One of the principal modifications in the design of the boat is the placing of the rudder in front of the propeller, so as to avoid the necessity of extending the keel as a support for the rudder frame. The screws are placed in two transversal planes, and turn in the same direction. The machinery is composed of two triple-expansion engines, each one working a propeller, and they are supplied by two boilers upon the Du Temple system. M. Normand has profited by his own experiments, and the experiences of Messrs. Yarrow, in suppression vibration, and this is done partly by equalising the weight of the pistons. At the trials the engines developed 2800-horse power without forced draught, and the consumption of coal did not exceed 900 grammes per horse-power per hour. Under these conditions the speed attained was 27·22 knots. The famous boat, which ought to attain a speed of 30 knots, is still in its experimental stage, and M. Normand himself does not seem to be very sanguine as to its ultimate success. The law which was passed in France last year reducing the premium upon foreign-made vessels sailing under the French flag to the profit of vessels constructed in that country, has already given a stimulus to the native shipbuilding industry. Though only commenced at the beginning of this year, the Ateliers et Chantiers de Normandie, belonging to MM. Laporte et Cie., have just been inaugurated at Quevilly, near Rouen. The plant is very extensive and is of the newest description. There are five stocks upon which vessels of large dimensions can be built. At the inaugural ceremony the keel of a steel sailing vessel of 2500 tons was laid down for a new company at Nantes, which has been formed under the title of the Societe Anonyme des Voiliers Nantais. As several other contracts are being entered into, the prospects of the shipbuilding industry at Rouen are encouraging.

### HADFIELD'S PROJECTILES FOR TREATED PLATES.

Messrs. Hadfield have for some time past advocated a shot with a special form of head for the attack of treated plates, and Dr. White, the Director of Naval Construction, has given facilities for experimenting with it recently on board the Nettle. The details of the trial are not published, but Hadfield's shot behaved very well compared with those of the service form, showing considerable advantage in penetration. The projectile was broken up, but not to the same extent as those of service form. Further trials may be looked for, we presume, and we do not know the precise shape of head, so that it would be premature to venture an opinion on the prospects and merits of this shot. Our impression as to the action of treated plates, as we have before said, is that their power consists in fracturing the shot's point. When this, for any reason, is not effected the treated plate seems to offer no advantage. This has been illustrated by shot striking at low velocities and also at very high ones. The wrought iron cap assists the shot simply because it prevents fracture. Consequently the wrought iron cap when tried in Russia against non-treated plates offered no advantage, being fired under conditions when the shot would not break without the cap; indeed, under these circumstances it must offer a slight additional obstacle to its penetration, but imperceptible in its amount. It is easy to see that Hadfield's blunt point is less likely to break than a sharp one. On the other hand, any device which enables a sharp point to remain unbroken ought to offer advantages over a blunt-pointed shot for direct penetration. The question of service conditions has, however, to be considered. We should much like to see more firing at an angle with treated plates.

## LITERATURE.

*The Next Naval War.* By Captain S. Eardley-Wilmot, R.N. London: Edward Stanford.

We cordially welcome this latest addition to the literature of this class for several reasons. Anything, whether written or spoken, which will help to stimulate the public mind to an intelligent interest in the first line of defence of the country is a subject for gratitude, for the ignorance and apathy of the mass of the inhabitants of these isles where the Navy is concerned is to the last degree astonishing and deplorable. When we have a book, notwithstanding that it be small such as this, by an officer of great and recent experience in his profession, his statements and opinions should be doubly interesting and instructive. We are glad to see that the book before us is now in its third edition, for whatever expectations the politician may have for the future, the more widely the strictly naval points are driven home the better. In his story of the defeat of the unsupported Mediterranean Squadron by the stronger French fleet, Captain Eardley-Wilmot emphasises points upon which there should be no real difference of opinion. They are the insufficiency of our system of manning the fleet, the divided control of War-office and Admiralty in the defence of our ports, and the lack of co-operation generally between the two services, and perhaps in a less degree, the want of accommodation at Gibraltar for the temporary repairs of our ships. The last difficulty might be met to a large extent by the increase of our Mediterranean fleet, for the rest a good deal more is wanted. They are matters vitally affecting our position as a naval power. We shall not attempt to tell the author's story; that should be read and re-read. The torpedo attack on the ships in Portsmouth Harbour may strike some as improbable, but it is quite possible under the existing system, and as might be expected when Captain Eardley-Wilmot is the writer, a good deal is made of the torpedo as a weapon of attack.

*The Junior Engineering Society.* Record of Transactions. Volume III. Twelfth Season 1892-3. Edited by W. T. Dunn, Secretary. London: The Society.

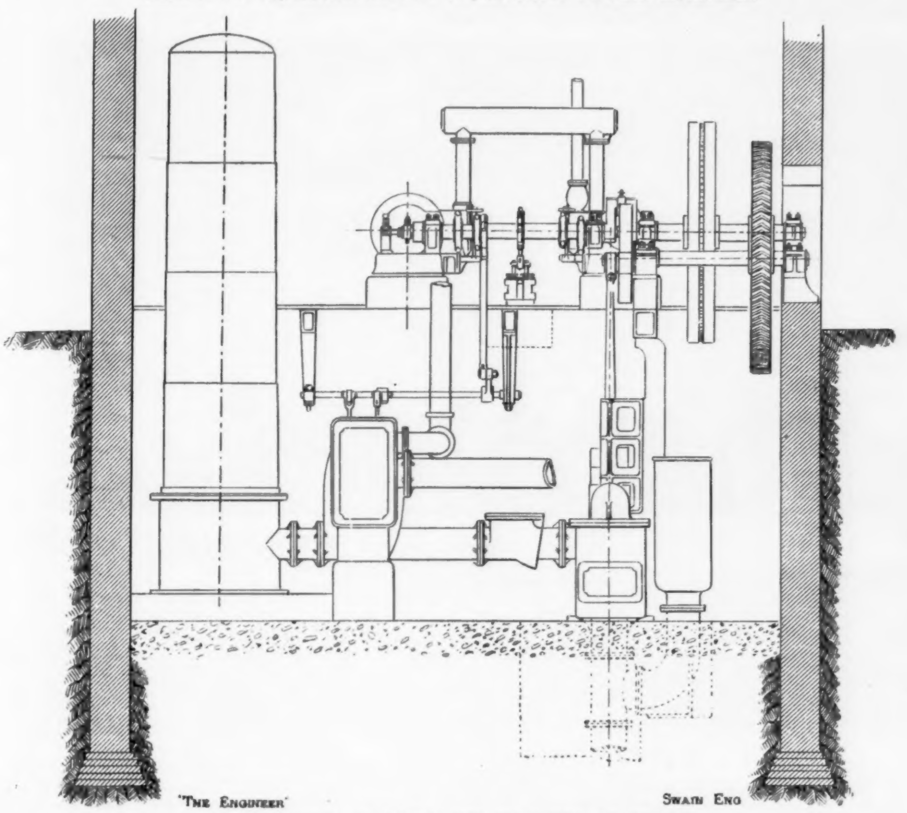
This Society, founded in 1884, now numbers about four hundred members, and by the very active attention of its secretary it has succeeded in attracting a good deal of support, and has published a considerable number of admirable presidential addresses and papers read and discussed. The society has always had an eminent man as a president, but he is not expected to afford time for more than two or three appearances. They include Dr. William Anderson, Sir E. J. Reed, and Professors Kennedy, Unwin, Perry, Thompson, and lastly, Dr. John Hopkinson. The volume before us contains papers on Electro-motors of Small Power, by D. T. and A. C. Heap; Cost of Electric Supply, by Dr. Hopkinson; Expansion Curves, by W. J. Tennant, a paper which is accompanied by a very useful diagram, or what would be so with a little fuller description, which will probably be given in another volume; Feed-water Heaters, by W. H. De Ritter; Gold Mining Machinery, by A. H. Brunly; Sanitary Engineering of Dwellings, by R. W. Newman; and Water-tube Steam Boilers, by H. Fraser, and numerous well written notices of visits to works.

## PARLIAMENTARY NOTE.

*Railway in Uganda.*—On Monday questions were asked in both Houses as to the policy of the Government with reference to Uganda. Amongst other matters, Lord Kimberley stated that the Government had in view a monthly transport service to Uganda, and that a steamer and some launches were to be sent out for service on Lake Victoria Nyanza. Unfortunately no satisfactory answer could be obtained as to the construction of the proposed railway. Lord Kimberley said, "With regard to the inquiry what we are doing in the matter of roads, I would point out that it is very difficult for us to undertake any considerable works of that sort on account of the uncertainty of the position we occupy with regard to the East Africa Company. Until we come to terms with them it will be difficult for us to embark on any considerable works of that kind even if they were thought desirable." On the whole it is to be gathered from the attitude and statements of the Government that it is not at present impressed by the necessity, or even the expediency, of a railway at all.

# KIDDERMINSTER WATERWORKS—PUMPING MACHINERY

MESSRS. WORTH, MACKENZIE AND CO., STOCKTON-ON-TEES ENGINEERS

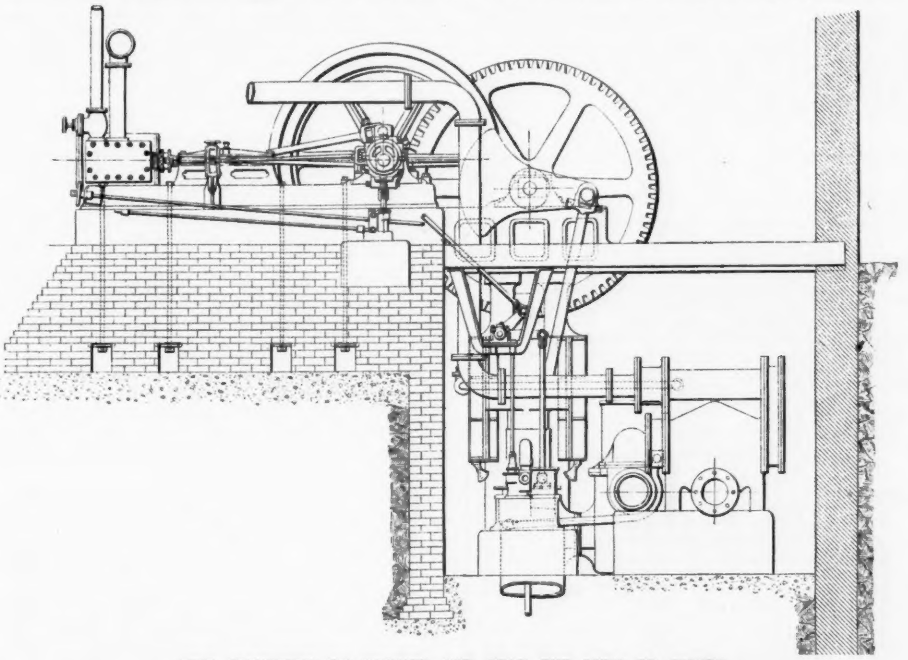


SIDE ELEVATION OF PUMPS—END ELEVATION OF ENGINES

## KIDDERMINSTER WATER WORKS.

Kidderminster may consider itself exceptionally fortunate in its water supply, which is drawn from deep bore holes in the new red sandstone rock, and is of excellent quality both for domestic and manufacturing purposes, having an average hardness of only 8·58.

These works were commenced in the year 1870, when a well 8ft. diameter was sunk to a depth of 113ft., and from the bottom of this well a 12in. bore hole was put down to a total depth of 500ft., a supply of 360 gallons per minute being obtained. Two horizontal non-condensing engines were erected, each having a single cylinder 20in. diameter, with a stroke of 3ft. 6in., with variable expansion gear of the "Meyer" type. The engines were supplied with steam by two Lancashire boilers working at 60 lb. pressure, and drove, through spur gear, a set of three-throw lift-pumps fixed in the well; only one engine and boiler were required to drive the pumps, the other being in reserve, the engines and boilers being thus in duplicate, but not the pumps. The pumps delivered into a reservoir on an adjoining hill top, from which the town was supplied, but the extension of the town causing the pressure from this reservoir to be insufficient, a stand-pipe was erected to give 30ft. additional head. In course of time this also became inadequate, and in the year 1885 a new reservoir was constructed on the top of a higher hill, about a mile from the pumping station; this reservoir holds about 2,000,000 gallons, and is sufficiently high to supply any part of the town. But again, in the year 1889, it became necessary to augment the supply from this pumping station, and for this purpose an additional well was sunk outside the present engine house, 4ft. 6in. diameter and 108ft. deep, with a 12in. bore hole, to a depth of 377ft., and a 6in. bore hole a further depth of 246ft., making a total depth—from the surface—of 623ft.; this well added about 140 gallons per minute to the available supply.



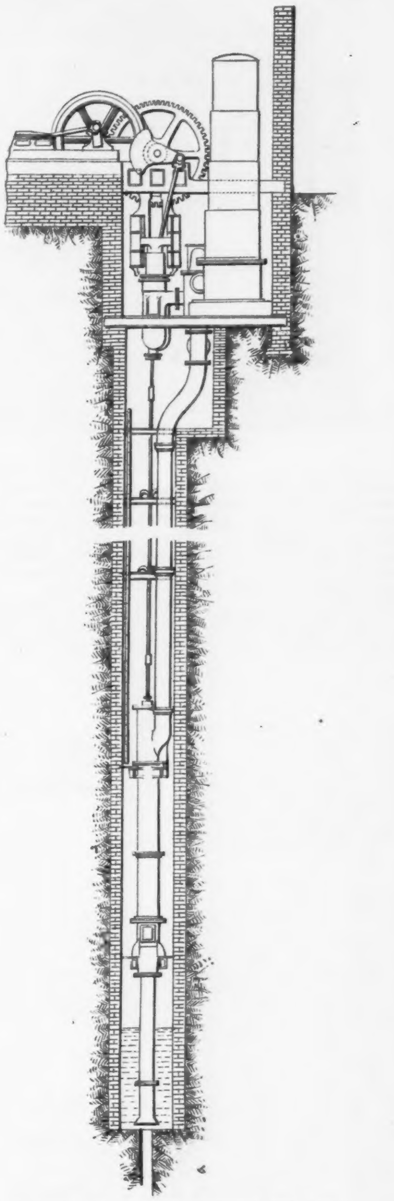
SIDE ELEVATION OF ENGINES AND GEAR—END VIEW OF PUMPS

The wells are only ten yards distant from one another, and a tunnel was bored from one to the other at a depth of 105ft.; a sluice valve is fixed in this tunnel, so that the wells can be isolated for repairs.

As the standing level of water in the well is at about 75ft. from the surface, and the pumps were partly drowned soon after the engine was stopped, and in addition, the arrangements for access to the valves being very inconvenient, it was resolved, on the advice of the borough engineer, Mr. A. Comber, C.E., to put down a new pump in the new well, specially arranged for convenient access, and also to put down economical compound engines to drive same. Of the various tenders sent in for this work three were chosen for further consideration, and a sub-committee was appointed to visit and inspect, in conjunction with the borough engineer, the work done by the selected firms. The last visit paid was to inspect the engines erected by Messrs. Worth, Mackenzie, and Co., Stockton-on-Tees, for the Stockton and Middlesbrough Water Board, and the Hartlepool Gas and Water Company. The committee were much pleased with these engines, and finally the contract was placed with that firm, and the plant they supplied is illustrated by the engravings we publish herewith. These engines were designed by Messrs. Worth, Mackenzie, and Co., and had to fulfil the following stipulations of the waterworks committee, viz., to raise, if required, 800 gallons per minute to a height of 200ft., working with the existing boilers at 60 lb. pressure, but to be readily convertible into triple-expansion when new boilers were put down, to require the minimum quantity of steam under both circumstances, and to be moderate in first cost. The old pumps, which did the work in one lift, having given a great deal of trouble, it was stipulated that the pumping should be done in two lifts.

The engines are coupled horizontal compound surface-condensing, with cranks at right angles, the cylinders being 14in. and 24in. by 24in. stroke, both cylinders are steam jacketed, and have separate hard cast-iron liners, and for conversion into triple-expansion the low-pressure liner would be reduced in diameter to about 22in., and a new high-pressure cylinder added tandem behind the present one. The high-pressure engine's bed plate is machined at the back end to allow of an additional piece being readily attached for carrying the 9in. cylinder.

In order to divide equally the work between the two cylinders, and to ensure the best possible use of the steam, both cylinders are provided with an expansion valve, adjustable while the engine is running, from 5in. to 15in., and provided with indexes showing the point of cut off. Full boiler pressure is used in both cylinder jackets, and the cylinders being lower than the boiler, a small pump is provided to drain each jacket. These pumps are 2in. diameter by 3in stroke, and deliver the condensed steam into the main feed pipe at a point between the feed heater and boiler; the rams, valves, glands, and bushes of these pumps are all gun-metal. The pistons are of cast iron, with largely extended bearing surface to prevent wear; the rings are the maker's angle section, fitted with Mather and Platt's patent steel coils. The piston-rods are of forged steel, connecting and excentric rods of forged iron, all finished bright; the crank shaft is of forged steel, made in two pieces, one piece having two cranks and pins forged solid with it, and coupled to the high-pressure engine in the manner usually adopted for coupling paddle-wheel shafts. This arrangement prevents any wear that may occur in the outer portion, due to the weight of the fly-wheel and gear, from injuriously affecting the engine bearings.



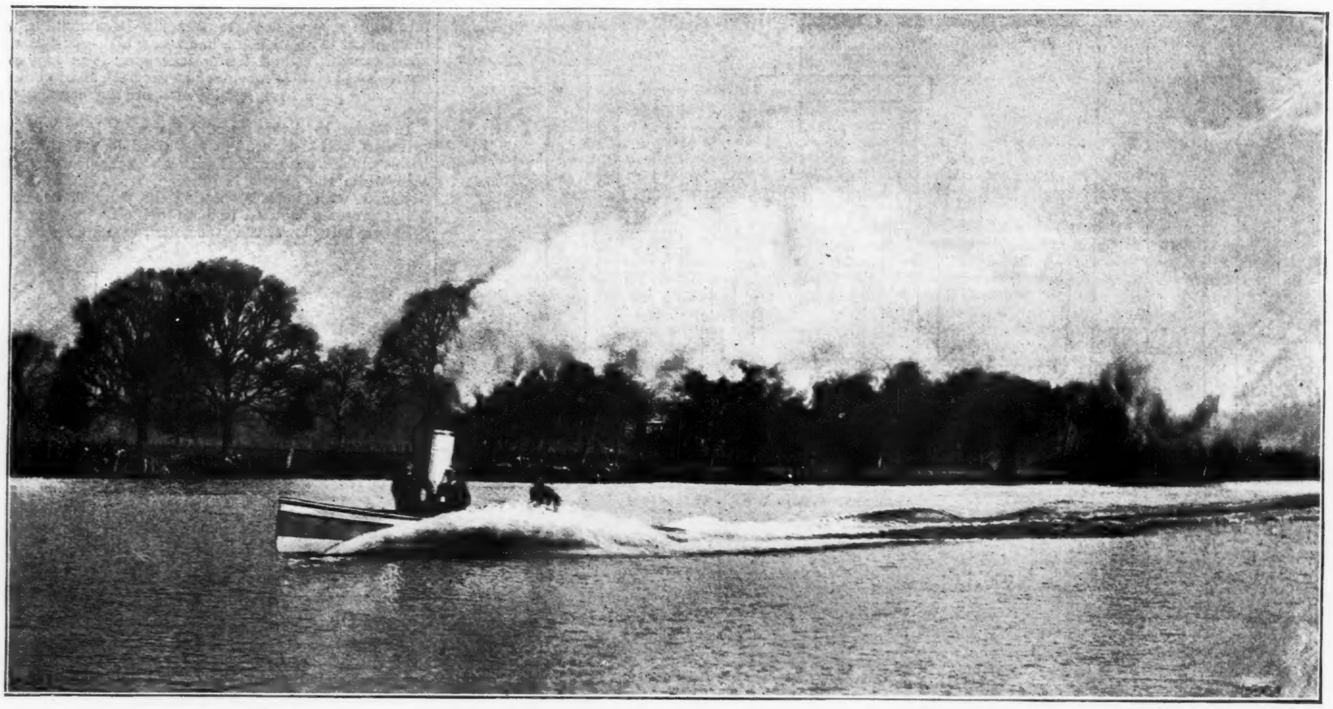
DRIVING GEAR AND SECTION OF WELL

All the bearings on the engine are phosphor bronze, and the crank shaft bearings are adjustable both vertically and horizontally. The fly-wheel is 8ft. 2in. diameter, four tons weight, turned up bright, and provided with barring rack. The gear consists of massive cast iron spur wheel and pinion, with double helical teeth, pinion 1ft. 9⅞in. diameter, and spur wheel 8ft. 6⅝in. diameter, 4in. pitch, and 9in. broad. The second motion shaft over the well is of forged steel, 6¾in. diameter at the bearings, and 7¼in. diameter at wheel seat; a cast iron crank with balance weight is keyed on the outer end of this shaft, and the remainder of the balancing necessary is provided for in the spur wheel.

The steam from the low-pressure cylinder passes through brass tubes, around which the feed-water circulates on its way to the boilers, thus raising the temperature to about 140 deg.; after passing through these tubes, the steam descends, and enters the tubes of the surface condenser, around which

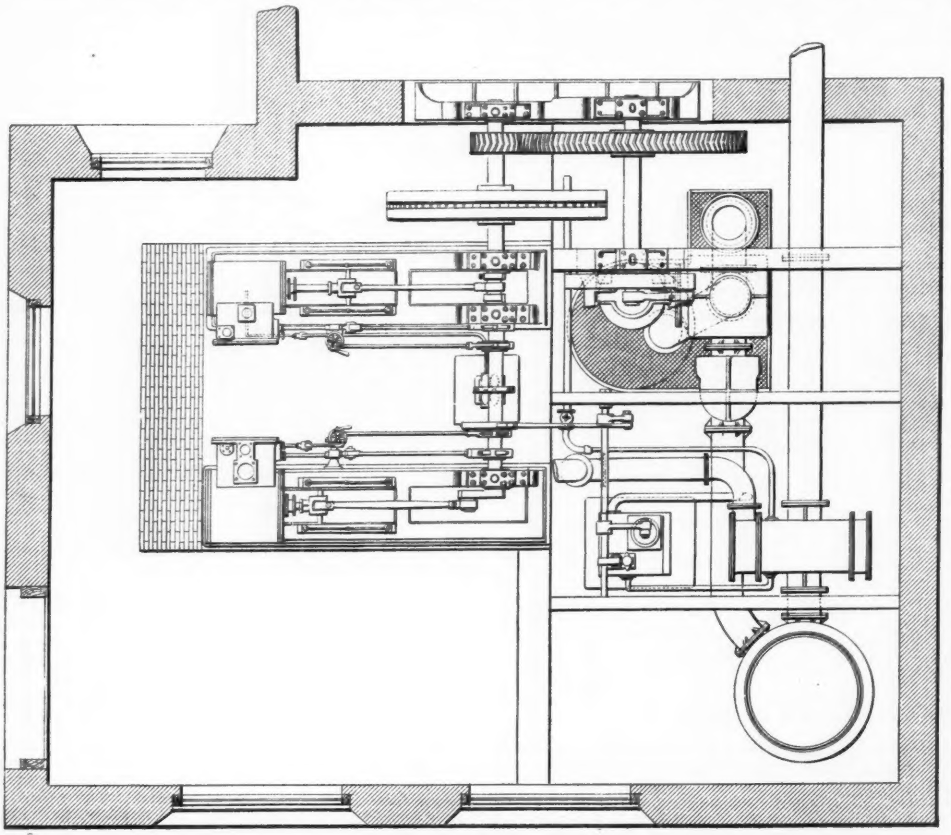
# THE HIBERNIA—THE FASTEST RIVER LAUNCH AFLOAT

DESIGNED BY MR. G. F. C. DES VIGNES; BUILT BY MESSRS. SIMPSON AND STRICKLAND, TEDDINGTON



passes the whole of the water being pumped. The air pump is 10¾in. diameter, 12in. stroke; the feed pump is 2¾in. diameter by 3½in. stroke, both worked from a rocking arm driven by an excentric on the engine shaft. The pumps, condenser, air vessel, non-return and relief valves, are all arranged on a lower level than the engines, and reached from the engine-room by an iron ladder.

The well pump is 18in. bore, with a stroke of 4ft., and the top cover of this pump is 72ft. below the ground, being thus 3ft. above highest water level. A platform is placed in the well, conveniently arranged for removing cover, when the bucket and bottom clack can be readily withdrawn. Below the top cover there is a breeches pipe forming the junction with the rising main, and below this again there is a length of pipe 19in. inside diameter, to the lower flange of which the working barrel is connected. The suction pipe is 14in. diameter, the lower end of which reaches to a depth of 107ft from the surface.



KIDDERMINSTER WATER WORKS—PLAN OF MACHINERY

As it was intended to repair the machinery in the old well as soon as the new works were started, after which repair the water could always be kept down in the wells, doors are arranged above the suction valve and pump bucket, by means of which access to the valves can be had in a readier manner than drawing through the top. The suction and bucket valves are of best gun-metal, of the double-beat type, and the bucket is provided with phosphor bronze rings. The force pump at the top of the well has one ram 18$\frac{11}{16}$in. diameter, worked by a connecting-rod from the balanced crank; a steel rod is continued from the bottom of the ram, passing through a gland on the bottom of the ram pump, and connected to the rod working the lift pump. These rods are connected together by machined sword joints, so as to be easily and quickly disconnected, should it be necessary to draw out the pump bucket. These rods are of forged iron, and are guided by rollers so as to decrease the friction. The valves of the ram pump are eighteen in number, of hard gun-metal, and of the spiral wing type, and doors are arranged so that the valves can be readily examined when necessary. After leaving the valve box of the ram pump, the water passes through the non-return valve into the air vessel, which is 4ft. diameter by 20ft. high, and from the air vessel it passes through the surface condenser surrounding the tubes in which the steam is condensing, and thence direct to the town's main.

No official trials of these engines have been carried out to ascertain the exact coal consumption. A rough trial by the Corporation's own men, during the first week the engines were running, showed a consumption of 1 ton 13 cwt. per twenty-four hours, as against 4 tons 13 cwt. by the old engines in the same time, the result over twelve months proving equally satisfactory. Of this result, the *Kidderminster Shuttle*, in the report of the meeting of the Town Council, in the issue of November 12th, 1892, gives the following particulars:—"The new engines started on the 27th of October last have been in constant work, and performed the duty satisfactorily. . . . There has been a saving of 1016 tons of coal = £345, and a gain in water pumped of 8,512,360 gallons. The annual cost of repayment of principal and interest on the sum expended on the new engine house and engines is £213, so that there is a clear saving of £132 per annum in favour of the new engines as against the old." The Mayor, in moving the adoption of the report, also says:—"With regard to the work of the Drainage and Waterworks Committee, he was pleased to see that a great saving in coal had been effected by the new engines, and they were very much indebted to the borough engineer for his skill and energy in having the alterations made. The saving was something altogether out of the ordinary run. He hoped similar alterations might be made at the other engines belonging to the Corporation. Spending money sometimes was the truest economy."

We give the above report somewhat fully, because the Mayor's concluding remarks might with advantage be considered by many Town Councils. We believe there are scores of cases in which pumping engines are using three times the fuel necessary, and in which judicious alterations would give similar results to those obtained at Kidderminster.

In the autumn of 1892, the old well and bore hole having been cleaned out and deepened, a practically new pump was fixed in this well, and driven by one of the old high-pressure engines. This pump was designed by the borough engineer, to work in the valve boxes, pipes, and connections of the old pump, and the work was carried out by the Corporation's own men; it has made a thoroughly substantial and efficient job, and having been fixed at a lower level, and the old well being also the deeper, it can draw the water down to a level about 5ft. lower than the new pump. In consequence of this about another 10 per cent. increase of supply has been obtained, and this was all needed in the dry season of 1893. But as this pump had to be driven by the old wasteful high-pressure engine, it was resolved to compound this engine, and this work was also entrusted to Messrs. Worth, Mackenzie, and Co.

In the engine as compounded the cylinders are 12½in. and 29¼in. diameter by 3ft. 6in. streke, with expansion valves to both cylinders; the feed-heater, surface condenser, air and feed pumps belonging to the new engines are all arranged to be common to them both, and to be connected to one engine or the other in a few minutes as may be required. The whole cost of these alterations will be covered by the saving in coal in twelve months' working, and as the pumps in either the new or old well are capable of lifting much more water than the well can yield, the deepening of the wells for increased supply, which will probably have to be undertaken in another year or so, will be rendered an easy matter.

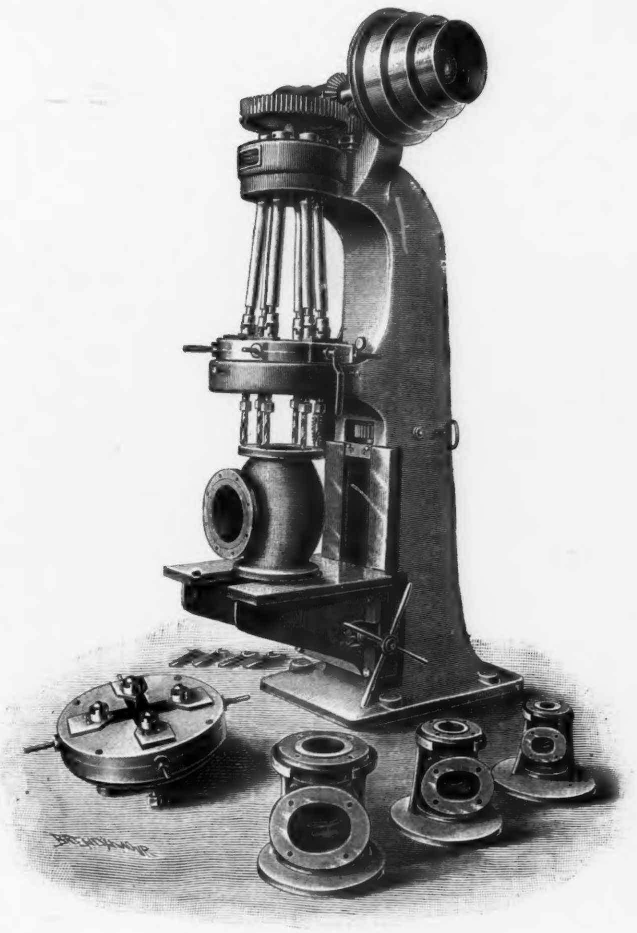
In addition to the pumping plant above described, the supply was also increased in the year 1879 by sinking another well and bore hole near the town; the yield from this well is about 380 gallons per minute, which is pumped direct into the town main by a pair of condensing beam engines with bucket-and-plunger pumps.

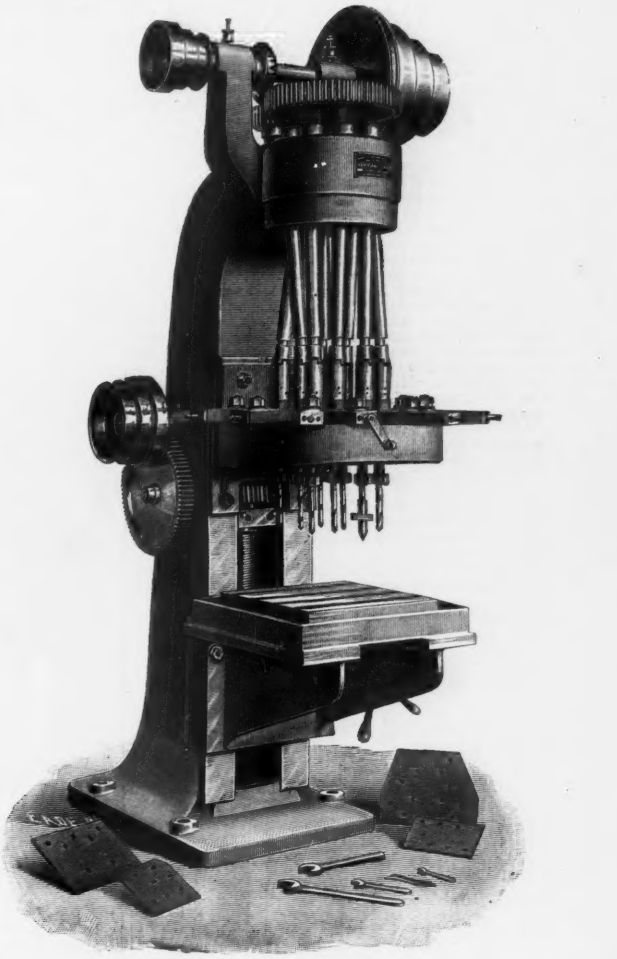
## THE HIBERNIA—THE FASTEST RIVER BOAT AFLOAT.

The above engraving represents the Hibernia, a boat built and engined from the designs of Mr. G. F. G. De Vignes, by Messrs. Simpson and Strickland, at Teddington. It is, we believe, the fastest boat of its size afloat, and a trip in it is an experience. At ordinary speeds the Hibernia behaves like an ordinary boat, cutting her way through the water and leaving a moderate impression in the form of shore waves. With a slight touch of the regulator she leaps forward, and as the speed increases, she gradually sinks a little by the stern, rises a little at the head, until at a certain high speed the bow rises clean out of the water, and the boat flies along at the top of it, throwing a double wall of spray, between which she flies at a speed of about 29 miles an hour with the stream, and

# MULTIPLE DRILLING MACHINE—ANTWERP EXHIBITION

MESSRS. HABERSANG AND ZINZEN, DUSSELDORF, ENGINEERS





26¼ miles against the stream, as measured and remeasured at Mousley. There is but little chance of making these speed trials, and very great risk in making them in this part of the river, for amongst other difficulties which arise are the objections which owners of houseboats urge against having their boats lifted up on the banks and left there. Some idea of the power of this boat, which is the property of Mr. R. H. Lebat, of Hampton Wick, may be gathered from the following statement of dimensions and engine power:—The length of the boat is 48ft. 3in. over all; breadth, 7ft. 3½in.; draught, 1ft. 4½in.; and depth of propeller below the water line, 2ft. 5in. The boiler is of steel, locomotive pattern, with barrel $\frac{5}{16}$in. thick, quintintupal riveted in longitudinal seams. The engines are two-cylinder, both high-pressure, 7½in. diameter, stroke 6in., revolution about 750 per minute up to 1050 revolutions per minute when doing the highest speed. The propeller has three blades of hammered double shear steel with carefully prepared surface and knife edge, keyed in a wrought steel boss and accurately balanced. The engines are of small dimensions, except in the wearing and hard-working parts, and here the dimensions are very large, and at first glance disproportionately strong. Every detail has been most carefully designed, and carried out with equally careful workmanship and excellent finish. The boat was built for Mr. Lebat, chiefly for umpire work at regattas and coaching university crews, and it began coaching for the last races within an hour of steam being first raised. From that time to about three weeks ago the boat ran over 3300 miles without the touch of a spanner, and at that time the propeller, having hit the good hard below Richmond, it was necessary to examine it, and the engines were at the same time examined, but no adjustment was necessary except in the two big ends. We have never seen a finer piece of work than these little engines, and Mr. Lebat is to be congratulated on the high quality and performance of both engines and boat.

## THE PHŒNIX DRILLING MACHINE.

In The Engineer of August 3rd there was a short notice of a new multiple drilling machine, made by Messrs. Habersang and Zinzen, of Düsseldorf, which is being exhibited at the Antwerp Exhibition. Several different types of this machine are made, of which our illustrations show two, both vertical, but the same principle is being applied to horizontal drilling and boring machines.

The chief peculiarity in this machine is, that the shaft which carries the drill is in three lengths: the upper or driving piece, the lower one which carries the drill, and the length which connects the two. This middle piece is joined to the others by clutch couplings. The inside of each clutch is hollowed out, and a steel ball is placed between the two lengths. The connecting pieces are in two parts, with spigot and faucet joint. Underneath the spigot is a strong spiral spring, which serves to press the two ends of the middle length against the balls. A central vertical shaft is driven by means of bevel gearing from a horizontal shaft carrying a belt pulley, and on this shaft is a spur wheel, driving six spur pinions on the upper lengths of the drill shafts. Thus these upper lengths are always vertical, and their centres are always in the same position. The lower lengths, which carry the drills, are also always vertical, but they can be made to change their positions, and the method of effecting this change constitutes the difference between machines Figs. 1, 2. The middle lengths have generally an oblique position, but the springs are sufficiently powerful to ensure that the balls are always pressed firmly into their sockets. A belt from a pulley on the main shaft to another one at the side of the machine drives a worm wheel, by which the table is slowly raised, as the drill spindles cannot be lowered.

Fig. 3—DRILL SPINDLE HOLDER

The A type of machine—Fig. 1—is intended for drilling flanges or similar objects, where it is necessary that all the holes should be equidistant from a common centre. They can be made with five, eight, or any other number of spindles, but the one shown in the illustration has six. The lower lengths, holding the drills, are carried by a circular drill holder, supported by a ring projecting from the middle of the cast iron frame of the machine. When four equidistant holes are required, the holder which is in position is taken out, and the one shown on the ground is substituted. The drill holder has radial slots, allowing the guides which carry the drills to move to or from the centre. These guides are connected with one another by bevel gearing, and they work on screws. The end of one of these screws projects, and when turned to the right by means of a wrench or key, it moves all the drills further apart, whilst turning to the left brings them nearer together. By means of a scale on the drill-holder, and an index on one of the guides, the machine can be set to the pitch circle required without measuring. In the smallest current size of this machine the diameter of the pitch circle varies from 1¼in. to 4in., and in the largest from 4in. to 16in.; but horizontal machines are being made with pitch circles up to 40in. diameter. For boring holes in the flanges of pipes, &c., the horizontal machine is made with two sets of drills, and the position of the heads are adjustable so that the flanges at each end of a pipe can be bored simultaneously.

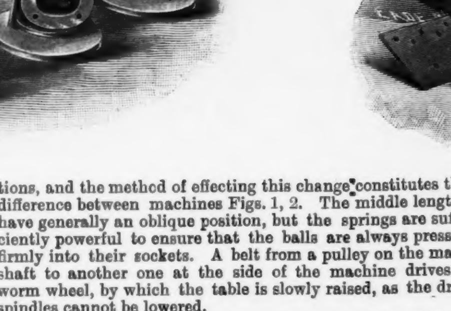


Fig. 4—DRILL SPINDLE HOLDER

The jointed drill spindle is the same in the machine—Fig. 2—as in the one already described; but instead of the circular drill holder there is a strong ring with a circular slot. Separate holders are provided for each drill spindle, and these are held in position by a bolt running in the circular slot. There is also a slot in each of these holders, so that they can be made to slide backwards and forwards, as well as to take any position round the circle, and they are then secured by the bolt. When necessary, the plate carrying these holders is divided into degrees, so that the machine may be set for the same work as the other. But in this machine the chief advantage is that the drills may be set in any irregular relative position, so that the larger sizes of the machine are useful for cover plates and similar pieces of structural ironwork, and the smaller ones for knife handles, locks, &c. 360 ¾in. holes were recently drilled through ⅝in. iron plate in an hour by an 8-spindle machine, and one of the smaller machines has drilled 1000 holes in the same time.

The two smaller illustrations show the drill holder of a third type of vertical machines combining the advantages of the other two. Radial grooves are cut in the circular piece, which carries the drill guides, and there are similar grooves in the guides. When a strip connecting these is inserted they can only move radially. In Fig. 3 the drills are equidistant, whilst in Fig. 4 they are in no regular position. In the larger machine there is an ingenious arrangement for preventing the waste of oil. All that falls on the table passes down a pipe into the receptacle in the frame, from which it is raised to the top of the machine by a small centrifugal pump, to be used again.

## METHODS OF DETERMINING THE DRYNESS OF STEAM.[1]

By W. C. Unwin, F.R.S., M. Inst. C.E.

The determination of the quality of steam, or its wetness, has come to be of very great importance both in boiler trials and engine trials. It was in the classical researches of G. A. Hirn at Logelbach in Alsace, in 1854-57, and in subsequent experiments by MM. Grostête, Hallauer, and Leloutre, and other members of the Société Industrielle of Mulhouse, that the great importance of the action of water in the steam engine cylinder was first clearly recognised. It was perceived that the water present in the cylinder, and which may amount to 50 per cent. of the steam introduced, was due to three distinct causes:—(a) Initial wetness of the steam; (b) condensation in the mass of steam due to adiabatic expansion; (c) the action of the cylinder wall. An accurate discussion of the results of an engine test is impossible if the initial condition of the steam is unknown, both because the total heat per pound of steam received by the engine depends on its dryness, and because water introduced with the steam increases the prejudicial action of the cylinder wall.

---

[1] Report of the Committee, consisting of Sir F. J. Bramwell, Bart. (chairman), Professor T. H. Beare, Mr. Jeremiah Head, Professor A. B. W. Kennedy, Professor Osborne Reynolds, Mr. Mair Rumley, Mr. C. I. Wilson, and Professor W. C. Unwin (secretary).

In boiler tests the evaporative efficiency is measured in pounds of water converted into steam per pound of coal. But if part of the feed-water supplied leaves the boiler as water entrained in the steam, the real evaporation is less than the apparent evaporation. The entrained water must be allowed for in estimating the evaporative efficiency of the boiler. Further, a boiler which supplies wet steam is a bad boiler, because wet steam is prejudicial to the efficiency of the engine, and it should be one object of a boiler trial to determine whether the steam is of good quality.

The earliest attempts to determine the amount of moisture in steam which have come to our knowledge were made during some boiler trials by a committee of the Société Industrielle of Mulhouse.[2] This committee tried three methods:—(1) A method of separation: The whole of the steam was taken through a spare boiler, without fire, in the expectation that the moisture would be deposited. The increase of water in the spare boiler during a trial was measured, and that part of the increase due to condensation by radiation was determined by a special experiment. (2) A condensing method suggested by Hirn: Some of the steam from a boiler under trial was condensed and its total heat determined. By comparing the total heat per pound with that of dry saturated steam the amount of moisture was ascertained. (3) A chemical method: Salt was introduced into the boiler, and the diminution of saltness of the boiler water during a test determined. It was assumed that moisture in the steam would be of the same saltness as the boiler water, and therefore the amount of salt removed measured the wetness of the steam. In these early trials only the second method appeared to give reasonable results. But the committee did not place full reliance on any of the methods tried.

*Origin of the water suspended or entrained in steam.*—There are three sources of the water found in steam:—

(1) By ebullition boiler water is projected into the steam space. Part falls back, but part is carried on in the steam current. The extent to which wetness may be thus produced depends on the activity of the ebullition, the area of the water surface, the volume of the steam space, the position of the steam valve, the density of the steam, and other circumstances. In certain conditions of the boiler water it foams, and the steam space is filled with vesicles. Under such circumstances the mechanically produced priming may be excessively severe.

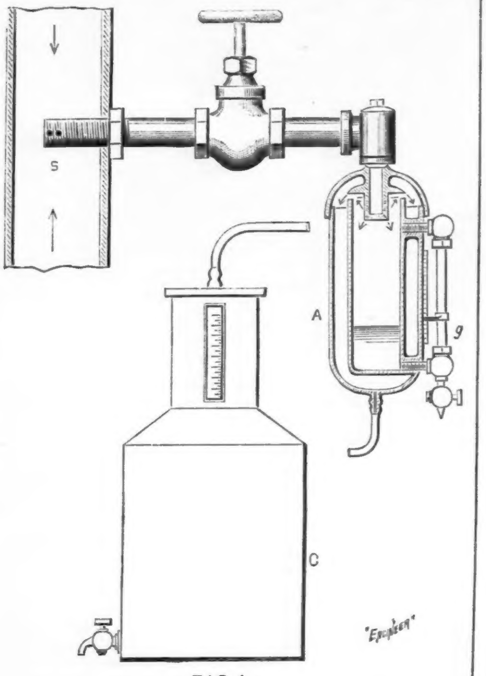

FIG. 1

As to priming of this kind some observations of Mr. Thornycroft on a boiler with glass ends are very instructive.[3] He states that "waters which cause priming on boiling produce foam, consisting of a mass of bubbles of various sizes. Water which is very bad produces bubbles so durable as to remain a considerable time without breaking, and by them the steam space of a boiler may be entirely filled. So soon as this takes place, instead of simply steam leaving the boiler, the discharge consists of foam, which is broken up in its rapid passage through the steam-pipe. With pure water, steam retains no film of liquid for sufficient time to be seen.

(2) The steam in the boiler is subject to variations of pressure. Bubbles formed under water rise to a region of less pressure. Fluctuations of pressure arise from the intermittent demand for steam. During expansions water must be formed as mist throughout the mass of the steam. It is difficult, however, to suppose that any great quantity of moisture is thus produced.

(3) The steam in the steam space of the boiler, and when flowing through the steam pipes, loses heat by radiation from the boiler roof and the surfaces of the pipes. To this must correspond condensation of part of the steam. Probably in some cases very considerable amounts of moisture are produced in this way.

*Methods of determining the wetness of steam.*—Very different methods have been tried by different observers to determine the amount of moisture in steam. Some method is required sufficiently accurate for practical purposes, and not involving excessively delicate measurements or complicated apparatus. It is proposed to describe all the methods which have been tried which seem at all likely to be useful, and finally to give the results of some comparative trials made for the committee which throw light on their relative trustworthiness.

I. *Weighing method.*—A method of direct weighing of a known volume of a sample of steam has been proposed by Guzzi[4] and Knight.[5] A copper globe is used as a measuring vessel, which is placed in a receiver connected with the boiler or steam pipe. After filling it is taken out and weighed. Let V be the volume of the globe, $w$ the weight of wet steam in it. Let $(1 - x)\,w$ be the moisture, and $x\,w$ the steam in the globe, and let $v$ be the volume in cubic feet per pound of dry steam in the same conditions of pressure and temperature. Then

$$(1 - x)\,w = w - \frac{V}{v}$$

$$x = V/vw$$

The method is one obviously of excessive difficulty.

II. *Separating method.*—Attempts have been made to ascertain the amount of moisture in steam by measuring the quantity of water trapped in a separator, between the boiler and engine, through which the whole of the steam passed. Probably such separators are too small relatively to the amount of steam flowing through them to detain the whole of the moisture. Mr. G. A. Barrus, in using a small separator in connection with a super-heating calorimeter, noticed that very nearly the whole of the moisture was caught by the separator. In that case the quantity of steam passing through the separator is small.[6] More recently Professor Carpenter, of Cornell University, has brought out a form of separating calorimeter of small size which can be applied almost anywhere on a steam pipe or boiler, and which can be used with very great facility. The separating calorimeter—Fig. 1—consists of a vessel A, about 12in. by 3in., consisting of an inner chamber and a jacket. The steam from the steam pipe S passes first into the inner chamber, where the moisture is separated, and thence into the outer chamber. The separating chamber is, consequently, almost perfectly protected from radiation. As the water accumulates in the inner chamber its level is shown by a gauge glass $g$, and the amount can be read off on a scale. A very small orifice at the bottom of the outer chamber regulates the amount of steam discharged. The steam as it escapes passes through a flexible tube to a simple form of condenser C. The increase of weight of the condenser in any given interval of time is noted, and the amount of water deposited in the same time in the separator. If $x$ is the dryness fraction of the steam, $w$ the weight of water caught in the separator, and W the weight of steam condensed,

$$x = \frac{W}{W + w}$$

The scale on the separator is graduated to $\frac{1}{100}$ths of a pound. There is also a gauge glass and scale on the condenser, graduated to read pounds and tenths at a temperature of 110 deg. Fah. But as the variation of volume of the water with temperature affects the readings considerably, it is best to weigh the condenser, or at any rate to determine a correction of the scale for temperature. Professor Carpenter states that the dryness of the steam after passing the separator was tested in the laboratories of Sibley College by several observers, and with steam carrying from ½ per cent. to 60 per cent. of moisture. In every case the separation of the water from the steam was complete and perfect.[7] Other tests have been made with moderately dry steam, using the separating and throttling calorimeter simultaneously, and the results were practically identical. The instrument is very simple to use, and requires no pressure gauges or thermometers.

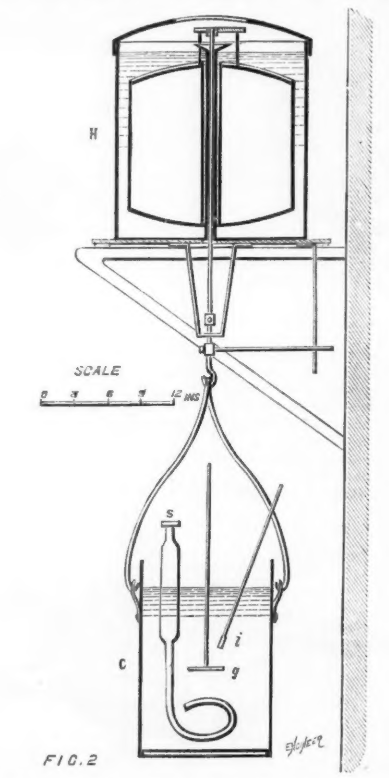

FIG. 2

III. *Condensing method.*—Suppose a known weight of the steam condensed and its total heat determined. By comparing this with the total heat of an equal weight of dry saturated steam, according to Regnault's Tables, the amount of moisture in the steam can be determined. The apparatus designed and used by Hirn in the Mulhouse trials in 1859—Fig. 2—is, so far as we know, the most convenient and perfect apparatus hitherto used in trials of this method. It consists of an iron vessel C, about 1ft. in diameter, furnished with a loose cover. This is the condenser. A small pipe and cock in the steam pipe deliver steam, through a small orifice near the steam pipe, into the pipe S. An agitator $g$ and a sensitive thermometer $i$ are provided. The condenser is suspended from a hydrostat H, which permits extremely accurate weighing of the amount of steam condensed. Let $x$ be the dryness fraction of the steam, $w$ the increase of weight of the calorimeter. Then the condenser has received $x\,w$ lb. of dry steam and $(1 - x)\,w$ lb. of water at the steam temperature. Let W be the weight of water initially in the condenser plus the equivalent reckoned as water of the condenser itself. Let $t$ be the temperature of the steam, and $i$ and $f$ the initial and final temperatures of the condenser water. Then

$$x\,w\,(1116 - 0{\cdot}71\,t) + w\,(t - f) = W\,(f - i)$$

$$x = \frac{W\,(f - i) - w\,(t - f)}{w\,(1116 - 0{\cdot}71\,t)}$$

To arrive at satisfactory results the temperatures must be read to $\frac{1}{10}$ deg. at least, and the weight of steam condensed determined very accurately. Further, it is desirable that the temperature $i$ should be about as much below the temperature of the place where the test is made as the temperature $f$ is above it. A correction is easily made for the small fall of temperature by radiation during the time the agitator is used to secure uniformity of temperature. Suppose the agitator is used for two minutes and the temperature $f$ then noted. The temperature is again noted two minutes later. The small observed fall is the loss in the interval by radiation, and is added to the observed temperature $f$ as a correction. In the Mulhouse experiments the initial and final temperatures of the condenser were generally about 60 deg. and 110 deg. Fah. The following table gives the results of the Mulhouse tests in 1859. They were made very carefully, and Hirn himself directed the tests.

The committee at Mulhouse in discussing these results point out their variability, and remark that a mean of numerous observations should be taken. This is probably true when the test is made on a small scale. In Mr. Willan's tests 1 cwt. of steam was condensed in each test, and this gives what is virtually a mean of numerous smaller tests. In the case of Trial 23, the Mulhouse Committee thought that the calorimeter underestimated the amount of priming water.

About 1860, Joule used a calorimeter very similar to the above, in order to determine the total heat of steam and verify Regnault's results. The paper describing the experiments[8] is interesting as showing that fairly accurate results can be obtained by this method, used on a small scale, when the observer is sufficiently skilful. The amount of steam condensed was only from 8700 to 14,100 grains in each test. Temperatures were read to three decimal places. The weight of water in the condenser was about 140,000 grains. The steam flowed into the condenser for two minutes. The steam must have been almost perfectly dry, as the following—mean—results show:—

| Pressure of steam. In. of mercury. | Total heat. Observed. | Total heat. By Regnault's tables. |
|---|---|---|
| 37·25 | 638·43 | 638·77 |
| 57·52 | 644·77 | 642·87 |
| 111·58 | 655·45 | 649·60 |

The method has been often used in determining the wetness of steam in boiler trials, but very often the arrangements have been so rough that no reliance can be placed on the results. A calorimeter of this kind is called in America a barrel calorimeter. The barrel test is carried out thus:—An ordinary oil barrel is used, fitted with an outlet valve. A set of tests are made following each other rapidly, and an average of the results is taken. The barrel is filled and a trial made, the results of which are discarded. The object seems to be to heat up portions of the apparatus and the barrel itself. The barrel is then refilled, weighed, and the temperature of the water taken. A steam pipe connected to the boiler is then blown through to warm it, and a movable pipe is attached leading to the barrel. The steam valve is then opened and the steam condensed in the barrel, till the temperature has risen to about 110 deg. Fah. The valve is shut, the movable pipe removed, the water stirred, and the barrel again weighed and its temperature taken. It is obvious that the proceeding is a very rough one. Losses of heat by radiation, &c., tend to make the observed total heat too small, and therefore the moisture in the steam too large. On the other hand, evaporation from the barrel tends to make an error of the opposite kind. It is known that in using this method in a rough way negative results are sometimes obtained.

Omitting Trial 23, the mean amount of water carried by the steam was 4·4 per cent.

Mr. P. W. Willans uses this method also to determine the wetness of the steam in his engine trials.[9] Mr. Willans uses a very large condensing tank weighing full about three tons, and placed on the platform of a weighing machine. The tank was first balanced so that the weighing machine lever just rose. Then a standard hundredweight was placed on the platform of the machine, and the poise adjusted so that the lever again just rose. The hundredweight was then removed, the temperature of the condenser was noted, and the steam condensed in the tank till the lever rose—making an electric signal. The steam at that moment was turned off, and the tank contained exactly one hundredweight of condensed steam. The condensing water was then stirred and the temperature taken. The thermometers were sensitive—1 deg. C. corresponded to 1in. in some of them—and they were carefully compared with standard thermometers. A very small radiation correction was made. The value of the dryness fraction found on different days was ·9996, ·9638, ·9949, ·9646, ·9976, ·9893, 1 0072, 1·0048, ·9987. The mean of all is 0·9911, showing an average of about 1 per cent. of moisture in the steam. In spite of the large scale on which the experiment was tried and the care taken, the results are rather discrepant, and two of them give values which it would seem must be erroneous.

# THE MOST ECONOMICAL TEMPERATURE FOR STEAM ENGINE CYLINDERS, OR HOT *v.* COLD WALLS.*

By BRYAN DONKIN, M.I.C.E.

To obtain the maximum economy, and to reduce condensation in steam engines to a minimum, should be the object of the engineer. More especially is this the case because he has to deal with such a very sensitive vapour as steam, which is easily and quickly affected when brought in contact with highly conductive metal walls. In working with steam cylinders the aim should be to obtain the maximum area of indicator diagram with the smallest amount of water, and not only to keep all the internal surfaces as dry as possible, but also to reduce to a minimum the depth to which the heat penetrates the walls. The author wishes to call attention to the importance of the question of the most suitable temperature of cylinder walls. It is with a view to determine this point, if possible, for a given set of working conditions, and a given temperature of steam, that the following considerations are laid before you. To diminish initial condensation, experiments have shown that it is essential to reduce the difference of temperature between the steam and metal in contact with it. If this difference is small the exchanges of heat between the metal and the steam will be less rapid, and a smaller proportion of the surface of the metal will be heated and cooled per stroke. In most steam engines the cylinder walls are much colder than the steam, and consequently from 40 to 50 per cent. of the steam entering is condensed during admission. But if the walls are hotter than the initial steam, condensation is much reduced. In a number of experiments, extending over several years, the author has invariably found that the nearer the wall temperature is to the temperature of the working steam, the greater the economy. When, as is often the case, the walls are 40 deg. to 60 deg. colder than the steam, both condensation and consumption of steam are greatly increased. In surface condensers the thin pipes are kept about 60 deg. to 80 deg. Fah. cooler than the exhaust steam, by means of cold water circulating round them, and efficient condensation is thus obtained. In steam engine cylinders, where the contrary effect ought to be aimed at, the arrangements made result unintentionally, but generally with complete success, in condensing great quantities of steam, by presenting large surfaces much colder than the hot vapour.

* Paper read before the British Association at Oxford.

Experiments show that walls hot, relatively to the steam, give economical, and walls relatively colder, uneconomical results. On the other hand, the metal cylinders may be heated too much, and heat sent to waste into the condenser or the air. This is the other extreme to be guarded against, but it is seldom found in practice. Unquestionably the walls can be too hot as well as too cold for the maximum economy. When, however, the temperature of the surfaces is somewhat higher, or about equal to that of the steam, the best results in steam economy are generally attained. This will hold good for any cylinder in any type of engine, single, compound, or triple. The walls should be rather hotter than the working steam inside. External radiation should be considered, and it must not be forgotten that to raise the temperature of the cylinder increases the loss under this head, which, however, is relatively small. The experiments added will, it is hoped, prove the marked advantage of raising the temperature of the walls. There are various ways of making these boundary surfaces hotter, the most usual being the application of steam jackets to the cylinders and covers. Another method is the use of superheated steam, which has been found by experiment to produce considerable economy. Not only does this steam raise the temperature of the walls considerably, but being superheated, it is able to part with its extra heat without condensing. A third arrangement is to pass the gases of combustion from a steam boiler or other furnace round the cylinder, thus forming a jacket of hot air. This has been tried but with little success, as the hot gases not only part with their heat very slowly, but deposit soot and dirt. Hot mercury jackets have also been used, as well as jackets having a vacuum in them. In steam engines it is important, not only to diminish the volume of the clearance spaces at each end of the cylinder, but especially to reduce the extent of the clearance boundary surfaces. All useless projections and hollows should be avoided, because it is the total areas of these surfaces that is heated and cooled at each stroke. In other words, so many pounds of iron are raised in temperature so many degrees, and it is heating up this weight of metal that produces condensation. The character of the clearance surfaces, whether rough from the sand or turned, clean or dirty, and their position, whether vertical, inclined, or horizontal, will also have some influence on the condensation. This is proved by recent experiments, which have shown that the water drops, caused by condensation, run off more or less easily from the surfaces, according to whether they are rough or smooth, and thus affect the transfer of heat by altering the thickness of the non-conducting film.

*Methods of taking the temperatures of cylinder walls.* — As the cylinder wall temperatures have such an important influence on the working of steam engines, it is desirable to adopt some reliable and practical method for ascertaining them. They should be taken in each experiment, and the working conditions of the engine varied. The author has employed a system which he has found convenient and easily applicable; but he hopes that as the subject is more appreciated, other methods may be proposed, particularly for taking the temperature of the innermost part of the cylinder walls, say from 2 mm. to ½ mm. thick. In quick-running engines it is this fractional thickness that fluctuates with the whole temperature of the steam range, often 100 deg. to 150 deg. per stroke. For some years the method adopted by the author has been to drill small vertical holes, 3in. long, into the cylinder walls or covers. In an ordinary 1in. wall, four or five holes, 1½ mm. diameter, can be made. These are filled with mercury, and mercurial thermometers about 1 mm. diameter introduced into them. In some of the earlier experiments 4 mm. diameter holes were used with 3 mm. thermometers. With an engine not working and with a given pressure of steam in the jackets, it is easy to check these temperatures, as they ought practically to correspond with those of the steam. Other ways of verifying this method were also adopted and found satisfactory.

Experiments have shown that the cylinder wall in any working engine is divided into two parts, the outer portion remaining at a constant temperature, and the inner, or what may be called the "periodic" portion, being heated at each steam, and cooled at each exhaust stroke. The relative proportions of these two sections, or the depth to which the heat penetrates the metal, depends chiefly upon the speed of the engine and the temperature of the cylinder. In the larger and non-fluctuating portion of the metal wall, the temperatures taken in the way above described are correct. In the smaller "periodic" part, however, the results will not be quite so accurate, as the fluctuations of temperature in the metal lag, to a certain extent, behind those of the steam, and the readings will be only a mean, and not represent the whole range of metal temperatures, except perhaps in very slow running engines. Had it been possible to use some more perfect type of electrical or metallic thermometer, the range of temperature of the part of the wall nearest the steam, shown in the thermal gradients, would no doubt have been greater, as represented by the dotted lines. It is, however, a difficult problem to determine accurately the highest and lowest temperatures of this innermost portion of the cylinder wall, say, 1 mm. thick, with an engine running at 200 revolutions, and having a temperature range of, say, 100 deg. But this question does not affect the comparison of the temperatures of the walls in these experiments, as they were taken in the same way throughout. The method has been described in papers in the "Proceedings" of the Institution of Civil Engineers, and thermal gradients are added both for jacketed and non-jacketed cylinders. A certain weight of metal, forming part of the internal surface of an engine cylinder, is first cooled to nearly the temperature of the condenser, and, during the next stroke is heated up very rapidly, about 100 deg. to 150 deg., to the temperature of the steam, at the expense of the heat contained in it. In a non-jacketed engine for instance, running only at 35 revolutions per minute, and having 1in. walls, the temperature at a depth of about 8 mm. from the internal surface was found to be constant, but at 1½ mm. from this surface the mercury in the thermometer rose and fell regularly at each steam and each exhaust stroke. The depth of heat penetration for the same speed is much smaller with hot than with cold walls; there is less weight of metal to be heated up by the steam at each stroke, and condensation is found to be less. From observations on a non-jacketed Revealer, with walls much colder than the steam, it has been found that the drops formed by the condensation of the steam vary from about 1·20 mm. diameter to 4 mm. diameter, but with hot-jacketed walls they never exceeded about ½ mm. The effect of time—or the duration of a stroke—should also be considered when studying the transfer of heat from the steam and the cylinder walls. Taking two experiments on the same engine not jacketed, one running at 220 revolutions, and the other at 117 revolutions, the temperature of the wall and the cut-off being about the same in both, the gain in economy was found to be 11 per cent., due to the higher speed. At the small number of revolutions, the time allowed for condensation on the walls was double, but nearly all the condensation takes place before the piston moves.

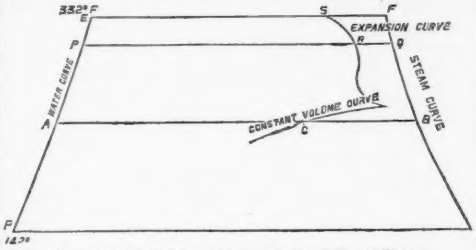
## THE TEMPERATURE ENTROPY DIAGRAM.*

By H. F. W. BURSTALL, M.A., Wh. Sc., Assoc. M.I.C.E.

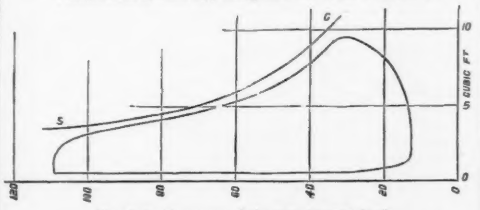
THE author has recently given an account of the construction and uses of this heat diagram before Section G of the British Association at Oxford, and in the present article proposes to deal with the question from a common-sense point of view. We are all familiar with the pressure volume diagrams which the indicator gives us direct from the engine; on such a diagram an area represents the external work that is done by the expanding gas contained in the working cylinder. It is often useful to know not only the work done, but also the heat which has had to be expended, to enable the engine to give out the external work; this heat is shown graphically by the temperature entropy diagram, which, in spite of its formidable name, is by no means difficult to construct and interpret. To the engineer the word entropy has no physical meaning, and it is often supposed that only the mathematician can deal with such quantities.

In order to fix the ideas, let the reader imagine for a moment that he has before him a vessel containing 1 lb. of water above absolute temperature denoted by T—that is, the temperature is measured from a zero 461 below the zero of the Fahrenheit scale. Now, let a small quantity of heat, say of thermal units, be added to the water, which, will of course, raise its temperature. If we divide the heat added by the absolute temperature T, we obtain a quotient which is called the entropy of the water for the given charge. In the case of water, the entropy is obtained by imagining the heat to be continuously added in very small quantities, and each time dividing by the absolute temperature at which heat is added, we thus obtain a very large number of very small quotients. The sum of the quotients has to be obtained mathematically, the result being that if we commenced adding heat when the temperature of the water was T and ceased when the temperature was $T^1$, the entropy for 1 lb. of water is $\log \frac{T^1}{T}$—the Napierian logarithm is obtained by multiplying the common logarithm by 2·3026. When the water reaches a certain temperature depending on the pressure, further addition of heat causes no further increase in the temperature, but the added heat is entirely expended in the formation of steam. The amount of heat required to convert 1 lb. of water into steam at the same temperature is found from the tables, and—to obtain the entropy—all that is required is to divide the latent heat of the steam by its absolute temperature.

It is convenient in drawing the diagram to calculate the entropy from 32; but any other temperature may be chosen. In the heat diagram vertical ordinates represent temperatures, and horizontal ordinates entropies. The water curve is first drawn by obtaining values of $\log \frac{T^1}{T}$ by intervals of, say, 10 deg. for the whole range required. The entropy of steam at the various temperatures is then calculated from the tables, and the values thus obtained are the lengths of the horizontal lines between the two vertical curves. The curved line opposite to the water curve represents the expansion of dry steam, and is the equivalent of what are called saturation curves on the pressure volume diagrams. In order to plot the actual expansion line of any engine on to the heat diagram, we make use of the fact that points along a line of constant temperature show how much steam at that stage has been formed from the pound of water, and the fraction $\frac{PR}{PQ}$ gives the percentage of steam, or what is generally called the dryness fraction. These dryness fractions are calculated for various points on the expansion curve of the indicator diagram, and the corresponding points found on the heat diagram. By joining these points, we obtain the equivalent on the heat diagram of the expansion line, and from that curve it is by no means difficult to see when heat is passing from the steam to the cylinder walls, or *vice versâ*. When the valve opens to exhaust, we have the pressure falling at constant volume until the bottom of the indicator card is reached. To draw these constant-volume lines is a simple matter. Let A B—Fig. 1—be a horizontal line at temperature T, and V the volume of 1 lb. of dry steam at that temperature; $x_0$ and $v_0$ the dryness and volume at the point where the constant volume curve commenced. If we take $AC = AB \frac{x_0 v_0}{v}$ C will be the point where the constant volume line cuts the line of constant temperature.



Temperature, Entropy Diagram, for 1 lb. of Steam



Absolute Pressure, 1 lb. per square inch

From the nature of the diagram, a vertical straight line expresses the fact that the entropy of the steam remains unchanged during the expansion, while the temperature alters; therefore constant entropy implies that no heat is added, or a vertical straight line represents the equivalent of what are known as adiabatic expansions on the pressure volume diagrams. By the aid of these principles it is easy to interpret the diagram of any given engine; when the expansion line tends towards the steam line the steam is receiving heat from the cylinder walls, and the water condensed in the earlier stages is re-evaporating; during the constant volume process heat is passing from the steam to the walls, as the curve there tends towards the water-line.

The area A E F D represents the heat available for useful purposes, the engines working between the given temperatures of admission and exhaust; this is the amount of heat which an engine could utilise if there were no losses due to initial condensation, incomplete expansion, &c. The area A E S R C is the heat utilised by the engine under consideration, and the area lying between the line S R C and F D is the amount of heat which the engine has wasted from preventible causes.

The writer considers that the heat diagram can be of real use to those who are engaged in practical work of engineering, as the diagram is a tool which will show graphically, and without abstruse mathematics, where losses of heat take place. As will be seen, the diagrams need only be made once as regards the steam and water lines, and tracings made from the drawing when it is required to tabulate the performance of any given engine.

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### ROUGH NOTIONS OF THE MECHANISM OF CHEMICAL ACTION.

SIR,—The following pretends to be no more than speculative, yet it may convey some idea serving as a useful provisional working theory perhaps—in the absence of any—of the *modus operandi* of chemical changes.

We assume molecules to be elastic in order to harmonise with the conservation of energy, and to explain the vibrations of molecules counted by the spectroscope. Secondly, we assume molecules to be of some open structure, so as to be got at or worked by the action of a medium—which freely penetrates even solids through the open molecular structure; and, for simplicity, molecules are taken on the average to have in three dimensions equal extension. The medium we suppose to be constituted as a gas with very minute atoms of excessively long mean path, so as to explain gravity according to a letter—for instance—published in THE ENGINEER, April 10th, 1891, "On the Dynamics of Gravity."

The gross molecules can then be forced together at their edges by the pressure of the streams of excessively minute atoms, which fly through the molecular open structure, sometimes bending the elastic molecules into crystalline forms, natural figures of pressure comparable somewhat to cells of bees.

The gross molecules being elastic and open—elastic filament of some kind—possess an elasticity of form which they tend to conserve, so that their open structure resists with some force attempts to bend it. This resistance in the case of some molecules may be so great as to prevent any notable bending of the molecular peripheries under the pressure of the streams of the atoms of the gas when any two of these gross molecules come into contact. Their elasticity of form prevents "combination," prevents that bending—supposing the filament structure of the molecules to be naturally curved, or even sometimes regularly circular—essential to ensure contact over an adequate surface-length for holding together under the pressure of the streams of minute atoms of the medium.

But let us assume two diverse molecules, say a molecule of hydrogen and one of oxygen, to touch each other at their peripheries. Then one molecule at least of these two may have a comparatively small form-elasticity—perfectly elastic, but less rigid—so as to bend or yield enough under the pressure of the atomic gas, whereby mutual contact over a considerable length of the molecular peripheries is ensured, or the two molecules consequently combine.

What is the effect of this? To shake the molecules violently, as is manifest, and if they are flexible they will vibrate and generate waves in the medium. We see then a flash of light at the combination of the mixed gases oxygen and hydrogen. Also vibratory motion can generate translatory motion, just as translatory motion can generate vibratory. Two freely-suspended vibrating tuning forks placed suddenly in contact will bound apart with some energy, converting vibratory motion into translatory motion, just as—conversely—two rapidly translated tuning forks will be thrown into vibration by their collision. So as we reason independently of scale, oxygen and hydrogen molecules translated towards each other are thrown into vibration, and this vibration of the compound molecules—steam—throws other compound molecules into violent translation whenever encountered, so that in this way—by the simple conversion of vibratory motion into translatory—an energetic translatory motion of compound molecules is set up; and this phenomenon, as a whole, we call the "explosion" of the mixed gases oxygen and hydrogen.

The explosion is initiated by some violent disturbance—a flame a spark, or a very energetic concussion—driving a group of molecules together into adequate proximity; and the wave of translatory motion thus set up spreads from the disturbed centre through the gas, knocking other peripherally elastic molecules into suitable proximity, or thus is their form-elasticity overcome sufficiently for chemical combination.

So it appears we may explain chemical "affinity" generally or broadly as an effect dependent on the elasticity of form of open structural molecules, or on their powers, greater or less, to retain the elastic shape possessed when they are free, which is synonymous, of course, with the power initially to resist approach.

An exceptionally unbending molecule would tend, as we may conceive, to group other more flexible ones about it as a centre; and it may seem relatively easy by the above considerations to explain the explosion of unstable compounds—including solids—by a mere touch. The molecules grouped about each other are nearly bent enough to ensure such a length of peripheral contact as to augment the effective pressure of the medium over the joined parts sufficiently to entail a new and more intimate approach, which occurs even by the slight pressure of the hand, accompanied by a fresh "explosion."

To turn to another branch of this subject briefly: We may remark that molecules united at their extreme edges or boundaries, which constitute crystalline structure, cannot slide or glide over each other, but—according to this view—a crystalline structure must break in any attempt to elongate it notably—take cast iron for example.

But if the elastic molecules be not united at their extreme edges, if they be jostled up sideways in layers, so that the filament boundary of one molecule may, for instance, cross another molecule diametrically or irregularly, as by the processes of rolling or hammering; then the molecules under an applied tensile stress can evidently slide over each other without parting, and so this may account for a bar of malleable iron stretching or elongating with ease when pulled. The molecules of the bar not being joined at their extreme edges or boundaries—as is essential to constitute the regular crystalline structure of cast iron, for instance—can glide, so it may be explained also, possibly, how the same molecules can sometimes assume the symmetrical shapes of crystals and sometimes not; how the same material may, under certain circumstances, be crystalline and under others not so.

To pursue the investigation further would be easy, but the above may serve as a sample of mechanical ideas of small scale motions and reactions under premises very simple, which we may venture to present. Moreover, we may be confident that simplicity of groundwork is the thing to be expected in the case of mechanical processes of whatever kind or scale which effectively serve their end.

S. TOLVER PRESTON.

Hamburg, July, 1894.

### ENTROPY.

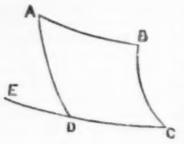
SIR,—Although Dr. Lodge declined to comply with Mr. Oldknow's request to give his own definition of entropy, he did define what he means by change of entropy, viz., that it is equal to the heat added during isothermal expansion, divided by the absolute temperature of expansion. We are therefore in a position to compare Dr. Lodge's change of entropy with the change calculated in accordance with Maxwell's definition of entropy. I have demonstrated that if Carnot's theory of heat is true, neither isothermal expansion nor compression is possible, and no one has attempted to point out any flaw in my demonstration, which, in fact, cannot be refuted. If then Carnot's theory of heat is true, Carnot's cycle cannot be carried out in the way described by Carnot, but the direct cycle can be so carried out, if the theory of the convertibility of heat and work is true, with the exception that the temperature of the source of heat must be greater than that of the operative substance during isothermal expansion, and the temperature of the body which receives the heat must be less than that of the operative substance during isothermal compression, so that the reverse Carnot cycle is an impossibility.

---

* Precis prepared by the author of Paper read before Section G of the British Association at Oxford, 14th August, 1894.

Maxwell gives the following definition of entropy:—"Let the body expand or contract without the communication of heat till it reaches the standard temperature, the value of which on the thermodynamic scale is T. Then let the body be kept at the standard temperature and brought to the standard pressure, and let H be the number of heat units given out or absorbed during this process. Then the entropy of the body in its original state is $\frac{H}{T}$."

Both Maxwell's definition of entropy, and Dr. Lodge's definition of change of entropy, are therefore based on the assumption that heat and work are convertible. Let, then, A B, B C, C D, and D A, represent the four stages of the direct Carnot cycle carried out in accordance with the theory of the convertibility of heat and work, A B being the stage of isothermal expansion. Let $t_1$ $t$ represent the temperatures on the Boyle and Marriotte scale of the stage of isothermal expansion and compression respectively, and let $T_1$ T represent the same temperatures on the absolute scale. Let $p_1$ $v_1$ represent the pressures and volumes at A, $p_2$ $v_2$ at B, $p_3$ $v_3$ at C, and $p_4$ $v_4$ at D. Let D E represent the curve of isothermal compression, when the pressure is raised from $p_4$ to P. Let P be adopted as the standard pressure, and T as the standard absolute temperature. In accordance with Maxwell's definition, the entropy of the body in the thermal state, denoted by the adiabatic curve A D, is equal to the heat emitted during isothermal compression, from the pressure $p_4$ to the pressure P, divided by the absolute temperature T, or is equal to



$$\frac{p_4 v_4 \log \frac{P}{p_4}}{T} = \frac{a\, t \log \frac{P}{p_4}}{T}$$

and the change of entropy produced by the heat added during isothermal expansion at temperature $T_1$ from the pressure $p_1$ to the pressure $p_2$, is equal to the heat emitted during isothermal compression at the temperature T from the pressure $p_3$ to the pressure $p_4$ divided by T, or is equal to

$$\frac{p_3 v_3 \log \frac{p_4}{p_3}}{T} = \frac{a\, t \log \frac{p_4}{p_3}}{T}$$

According to Dr. Lodge's definition of change of entropy, it is equal to the heat added during isothermal expansion at temperature $T_1$ divided by $T_1$, or is equal to

$$\frac{p_2 v_2 \log \frac{p_1}{p_2}}{T_1} = \frac{a\, t_1 \log \frac{p_4}{p_3}}{T_1},$$

because the ratio of the pressure is the same in both adiabatic expansion and compression, and therefore also in isothermal expansion and compression. If, therefore, the zero of the Boyle and Marriotte scale refers to the same thermal state as the zero of the absolute scale, so that $t_1 = T_1$, $t = T$, Maxwell's change of entropy is equal to Dr. Lodge's change of entropy, but otherwise not. Fashionable *fin de siècle* thermodynamicians are therefore in this dilemma: If they affirm that the zero of the Boyle and Marriotte scale refers to the same thermal state as the zero of the absolute scale, since the symbol, $a$, represents a constant number of foot-pounds, they have to admit that both entropy and change of entropy have nothing to do with the thermal state of the body, and, therefore, nothing to do with the science of thermodynamics. If they affirm that the zero of the Boyle and Marriotte scale does not refer to the same thermal state as the zero of the absolute scale, they have to admit that Maxwell's entropy is *toto cœlo* different from Dr. Lodge's entropy.

What is an entropy temperature? Is it supposed to be a temperature on Thomson's Absolute Scale? Entropy is neither a property of heat nor a property of matter. Why should the heat which has to be abstracted during isothermal compression, or added during isothermal expansion, in order to make the adiabatic curve of the relations between the pressure and volume coincide with an arbitrary standard adiabatic curve be called entropy: I must point out to "X." that the word is *entropy* not *entrophy*, and therefore has nothing to do with *nourishment*; and why the artifice should ever have been thought of use in the solution of thermodynamic problems surpasses the power of my imagination to conceive. WILLIAM DONALDSON.

August 17th.

### PATENT MUSEUM, SOUTH KENSINGTON.

SIR,—In connection with "Thamis's" letter in your issue of August 17th, it seems singular that unhappy visitors should be turned out of the above institution in broad daylight, a tidal wave of policemen sweeping them out at 4 p.m. winter and 6 p.m summer.

Perhaps it would tax too much the powers of the hardly-used electric light engine with the painful knock, mentioned by "Thamis," were it called on to contribute to the lighting of these galleries; but an ordinary individual would imagine that at any rate a few modest gas lights could be supplied, so that this interesting collection might be open at hours when business people could avail themselves of the opportunity of inspecting the exhibits, which, to many persons, are at least as interesting as the plaster casts, &c., over the way. E. J.

August 18th.

### THE EIGHT HOURS' DAY IN PORTSMOUTH DOCKYARD.

SIR,—It gave me much pleasure to read an "Old Dockyard Hand's" letter in THE ENGINEER of Friday. He seems to "know all about it," and we shall have some much wanted information.

I said that the men did not like the eight hours because they had to work all the time. I understand that the men undertook to turn out as much work in eight hours as they had before turned out in nine hours. Will your correspondent dispute this? I think not. If not, then it is clear that the men must work harder than they have done hitherto. That is precisely what I said, and I now repeat that there is widespread discontent in the yard in consequence.

As to the rate at which work is done, it is simply scandalous. I have seen the big slotting machine in the turnery working with an 18in. stroke paring the edge of a flange 2in. thick, the tool "going up on Monday, and coming down on Friday." In the same shop on the 12ft. face-plate, I have seen a 3ft. brass plate, an air-pump cover, or such like, with the tool cutting at the rate of 9ft. per minute. I could cite a dozen cases like that. The tools are about three-quarter speeded as compared with private shops.

As to the examinations, the facts are simply as I have stated them. The dockyard chaplain examined the boys, and for the most part he passed the dockyard men's sons instead of outsiders. It was quite natural and proper that he should give the benefit of the doubt to these lads, but the Radical party leaders hold the Established Church to be an abomination, so they "got rid of the parson" and got the Civil Service men to examine, with the result as I have said, that the sons of the dockyard mateys are left out in the cold, and the leaders who brought the change about are anything rather than popular in the dockyard. Now, either what I have said is true or it is not, and I challenge your correspondent to prove that I am wrong. Here are my questions.

First, is it or is it not a fact that the authorities insist on getting as much work done in eight hours as was previously done in nine hours?

Secondly, is it or is it not a fact that the men as a whole are disatisfied, because they have to work so much harder, and numerous little games have been stopped?

Thirdly, is it or is it not true that since "the parson was got rid off," the percentage of dockyard mateys' sons admitted as apprentices has been enormously reduced?

Before your correspondent answers these questions, I would advise him to talk to as many mates as he can handily manage. I fancy I know as much of the dockyard as he does, and I do not hesitate to say that I wish we had the old arrangements back again. KEPPEL.

Portsmouth, August 18th.

### ENGINEERS AND ARCHITECTS.

SIR,—With reference to the letter signed "Mechanical Engineer," although not in business on my own account, I have had a good many specifications through my hands, mostly, I may say, electrical, and it appears to me that far too much is left "to the satisfaction of the engineer." Is not the clause I have alluded to far too loose, and if sufficiently guarded, is its necessity obvious?

Of course, I am quite aware that it is in many cases quite impossible to specify in detail each minor item of an important contract, something must of necessity be left to the discretion of contractor and engineer, but I am referring to the general character of too many specifications.

To take an example. An architect accepts a tender on his specification (?) for the electric lighting of a new building, "the work to be done to the satisfaction of the architect," who trusts to making up his lack of knowledge of the subject by what he can pick up afterwards whilst the work is in progress. The result is either that the contractor under this clause is compelled to put in material, &c., which is far above what could be reasonably inferred from the specification, or that the contractor is refused his certificate, solely because the architect has seen something he likes, and insists on its adoption, quite regardless of the fact that such good material was not clearly specified, and that it is not covered by the contract price. I have had more than one case of the sort come before me, and I may say that I am not referring to contracting firms who will do jerry work if allowed, but those who will always give good value for their price. I was informed whilst in Sydney—Australia—some few years ago, that this clause was almost entirely suppressed in Brisbane, by a combination of builders refusing to tender for any work the specification for which included this clause. With regard to the moral question, I think there can be no doubt.

I consider that after a contract has been signed, the engineer or architect has no further concern with questions of cost, save only such adjustment of price as may be necessary on account of alterations or deviations from the original scheme—often necessary, and usually provided for by the specification—his duty being merely to see that the contractor maintains the standard of workmanship and material as laid down by the specification; and I also hold that when work is completed to the specification, or better, if contractor likes, that the engineer is then bound to issue his certificate, quite regardless of whether the purchaser is able to pay the money, his certificate being merely to the effect that certain work has been properly completed under the contract. In short, my own opinion is, that the engineer is in the position of an unbiassed judge between contractor and purchaser. G. T. P.

August 18th.

### THE LOCOMOTIVES OF THE UNITED KINGDOM.

SIR,—The following list, which I have compiled from the official details, shows the locomotive engines possessed by each company on the 31st December, 1893:—

| | Engines. |
|---|---|
| London and North-Western | 2735 |
| Midland | 2217 |
| North-Eastern | 1799 |
| Great Western | 1700 |
| Lancashire and Yorkshire | 1181 |
| Great Northern | 983 |
| Great Eastern | 962 |
| Manchester, Sheffield, and Lincolnshire | 715 |
| Caledonian | 698 |
| North British | 698 |
| London and South-Western | 636 |
| London, Brighton, and South Coast | 434 |
| South Eastern | 392 |
| Glasgow and South-Western | 335 |
| London, Chatham, and Dover | 210 |
| Taff Vale | 190 |
| Great Southern and Western | 178 |
| North Staffordshire | 142 |
| Great Northern of Ireland | 137 |
| Furness | 122 |
| Midland Great Western, Ireland | 114 |
| North London | 105 |
| Highland | 101 |
| Great North of Scotland | 92 |
| Rhymney | 72 |
| Metropolitan | 71 |
| Hull and Barnsley | 69 |
| Barry | 67 |
| Cambrian | 67 |
| Belfast and N.C. | 65 |
| Somerset and Dorset, Joint | 61 |
| Metropolitan District | 54 |
| Dublin, Wicklow, and Wexford | 54 |
| Waterford and Limerick | 46 |
| Midland and Great Northern, Joint | 39 |
| London, Tilbury, and Southend | 31 |
| Brecon and Merthyr | 29 |
| Maryport and Carlisle | 27 |
| Belfast and County Down | 26 |
| Alexandra Dock, Newport | 24 |
| Mersey | 18 |
| City and South London Electric | 16 |
| Wrexham, Mould, and Connah's Quay | 16 |
| Cork, Bandon, and South Coast | 16 |
| Severn and Wye | 12 |
| Londonderry (Sunderland) | 11 |
| Rhondda and Swansea Bay | 10 |
| Waterford and Central, Ireland | 10 |

There are also a number of small lines which possess from one to nine engines each, details of which it is not necessary to give.

Some of the companies—for instance, the Midland, Great Western, &c.—have in addition a number of old or duplicate engines which they do not include in their returns.

The total number of engines on 31st December, 1893, as officially reported, was 18,032. CLEMENT E. STRETTON, C.E.

Leicester, August 13th.

## THE JUNIOR ENGINEERING SOCIETY IN WALES.

THIS society, founded in 1884, has followed the lead of a large number of varied associations in selecting Cardiff as the place for its central annual gathering, prompted by the very hearty welcome extended by Sir W. T. Lewis on behalf of the Marquis of Bute, by the Dowlais and Cyfarthfa Iron and Steel Companies, the Barry Docks and Railway, and various leading industries. It has added to the comfort of the members that the commodious building of the South Wales Institute of Engineers in Park-place was unreservedly placed at their service.

On Monday they arrived in Cardiff from Weston-super-Mare, and in the absence of Sir W. T. Lewis, who was unfortunately unable to be present, were received at the pontoon by Captain Pomery, Mr. Hunter, Mr. David Morgan, and other representatives of the Bute Docks, and at once proceeded to inspect the many and special features of the East, West, and Roath Docks. Under such guidance, very systematically directed, the coal shipping appliances, hydraulic machinery, &c., were brought under notice, and most fortunately the members were enabled to include a thorough examination of the largest steamer that has ever entered the port of Cardiff. This was the Knight Batchelor, lying in the Roath Dock, with a carrying capacity of 9000 tons. She was built by Connell and Co., of Glasgow, and is being loaded with Powell Duffryn coal for India.

The cubic capacity of the steamer is 400,819ft. Her crew consists of fifty Lascars, five engineers, captain, and three officers, four European quarter-masters, a carpenter, and steward. After an exhaustive round, in which the special merits of the Lewis Hunter lift were favourably commented upon, luncheon followed, to which the Society was invited, on behalf of Sir W. T. Lewis, by Captain Pomery, and the remainder of the day was devoted to an examination of the Dowlais Works, Cardiff, under the guidance of Mr. Forster Brown, and the Cardiff Tin Stamping and Enamelling Works by the manager, Mr. Whittaker.

The unavoidable absence of Sir W. T. Lewis at the luncheon was the subject of regret by the Bute officials, as well as by prominent members of the Society. Captain Pomery remarked that, like themselves, Sir William was an engineer, who at one time had all the world before him; and at the present time he was one of the leading mining engineers of the country.

On Tuesday the members visited Cyfarthfa Works. They were met at the railway station by the secretary, Mr. Rogers; the chief engineer, Mr. Hamley; the furnace manager, Mr. Warton; the chief cashier, Mr. Harpur; the mill manager, Mr. Jones; and Lieut. Evans, son of the general manager, and after lunch proceeded to the works, where the new industry, the brick work, was keenly inspected, and its novel features of utilisation of waste forces noted. From thence to the coke ovens, where the leading features, and especially the gravitation of the coke to the blast furnaces, was noted. Next the blast engines and the engine room, all of which came in for high commendation. The engines in this department are of the finest type, duplex, and of great power, one by Davy Bros., Sheffield, date 1888, another by Stevenson, Preston. The great cleanliness and perfect clock-like movement of all come in for special comment, as does also the blowing engine by Adamson, of Manchester; the hydraulic engines by Tannett and Walker, Leeds; and the Galloway range, which was also another of the economic utilisation features of the works. The furnaces and the Bessemer, the rolling, and the mills generally, were next visited in order, and favourable comment passed on the "Skid" engine, which, under the guidance of a mere lad, transferred with great rapidity the steel bars from one point to another.

The visitors had not time to go over all the details, and had to leave the fitting shops, which are in perfect order, as well as the Cyfarthfa "exhibits" unvisited, but they had ample evidence given of the ability with which the leading ideas at Cyfarthfa are carried out, lessened manual labour, promptitude of make from the furnace to the finishing department, utilisation of waste heat, and the adoption of mechanical and engineering appliances in all possible ways. A mass of finished steel bar ready for rolling was the last detail that came under notice, and the members with unreserved praise hastened to the concluding visit of the day—the great colliery of the Dowlais Iron Company, at the Aberdare Junctra, where they were met by the management and taken over the whole of the colliery area, noting the great fan, winding engines, and perfect appliances now ready for the output of coal which apparently is in the near future.

On Wednesday the Society proceeded to Barry Dock, and were received by the officials and afterwards by Lord Windsor and Mr. Archibald Hood, and made a thorough and exhaustive inspection of the whole of the Barry Docks, which claims, and with justice, to take a high stand in mechanical engineering and electric appliances, into which we shall enter in our next. The reception by Lord Windsor was most gratifying, and the members wound up the day with a visit to Penarth Docks, where again the officials, Mr. Thomas, Captain Bangally, and others, extended a very cordial welcome, and gratified the Society with the advanced character of the means for rapid shipment. Mr. Beazley, jun., was present, representing the esteemed manager of the Taff Vale Railway.

## NOTES FROM JAPAN.

(*From a Correspondent.*)

IMMEDIATELY before the war broke out between China and Japan delegates from several of the Loochoo Islands were sent to Tokio to petition the Japanese Government to connect the islands with Kagoshima by a submarine telegraph cable. Owing to the outbreak of the war, however, there has been no satisfactory termination to the negotiations; but it is probable that at its conclusion they will be renewed, and, in fact, as a direct result of the war, improved telegraphic communication with Japan is likely to result.

The knowledge of the Japanese of telephonic and telegraphic matters now compares favourably with European information on these subjects; also, although any European novelty is readily adopted by the Japanese, the national instinct of protection tends to exclude goods manufactured in Europe; and the Japanese prefer to copy our inventions, but to manufacture goods for home consumption by means of Japanese labour, and with Japanese capital. Whatever may be the outcome of the war, however, the result will be seriously to impoverish the Japanese Exchequer, and if the rapid progress which has been going on during the last twenty years is to be continued, the Japanese will perforce have to welcome European capital, and to some extent European skilled labour.

Great difference of opinion exists as to the internal resources of Japan. A mining expert, however, who has had practical experience in the island in connection with the Ashio Copper Mines, regards the outlook in this direction as a very favourable one; and whatever may be the value of the natural resources of Japan, the Japanese are such a go-ahead race that the country should prove a good market for European enterprise, more particularly in connection with engineering work. The large amount of water-power in the island is extremely favourable to electric lighting schemes, and, where heavy plant is concerned, that of English manufacture should find a good market. Where heavy machinery is not required to turn out any given class of apparatus, the Japanese, who are skilful mechanics, produce good work, and in connection with those branches of electricity to which they have turned their attention, improvements in apparatus have been effected which bring Japanese instruments often to a pitch of perfection superior to similar instruments of English manufacture. Prices are, however, high, but the jealousy of European-made goods, to which we have referred above, is sufficient to procure a sale of home-made goods, even where the prices of these are high.

Electric lighting is progressing fairly rapidly, and two new installations have recently been put down—one at Okayama, and one at Maebashi, the former having a steam plant, and the latter a water-wheel. Both these places are now important towns, and the authorities, in adopting the electric light, have only followed an example set by other towns of the same standing.

A serious competitor to the electric light, however, is the incandescent gas light, which is making considerable progress, particularly in Yokohama, where, at the Club Hotel, it has surplanted the electric light. The railway stations at Yokohama and in Tokyo are also being lighted on this system.

The accidents in connection with the earthquake which took place in June have demonstrated the unsuitability of brick buildings to Japanese conditions of existence. The native lath and plaster structures scarcely suffered; and even in the event of their coming down, the materials are so light that serious injury seldom results. Nearly all the modern brick buildings, however, have suffered severely, and if the earthquake had occurred in the night, great loss of life must have resulted. In some few instances, where the brick buildings were of exceptionally solid construction, they withstood the shock, and the iron chimneys which are used in connection with some of the electric lighting stations were also quite unharmed. The experience gained in connection with the recent earthquake will probably lead to an extensive adoption of these chimneys, in place of those of brick construction, nearly all of which came to the ground in places where the shock was severe.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

Authoritative details are this week available of the changes in the American tariff as they affect the iron and steel railway material, and some other of the trades of this district. Iron and steel sheets valued at three cents per lb. or less, from 10 w.g. up to 20 w.g., will now pay a duty of 0·7 cents per lb., against 1 cent per lb. under the old tariff; sheets up to 25 w.g. 0·8 cents per lb., and thinner than 25 w.g. 1·1 cents. Galvanised corrugated sheets are rated at ¼ cent per lb., above the rates just mentioned upon the corresponding gauges, as against ¾ cents under the old tariff. Polished or planished sheets are rated at 1¾ cents, against 2½ cents, and cold-rolled sheets are rated at ⅛ cent per lb. more than the corresponding gauges of black sheets. Iron and steel hoops are rated at 30 per cent. *ad valorem* against 1 cent per lb. under the old tariff. Special provisions are made respecting cotton ties cut to lengths for baling cotton. Ties of 8in. or less in width, and less than ⅜in. thick, and not thinner than 10 w.g., will have to pay 1 cent per lb.; from 10 w.g. to 20 w.g. 1·1 cent per lb., and thinner than 20 w.g. 1·3. cent per lb. Wire rods from Nos. 0 to 6, valued at 4 cents or less per lb., are charged 0·4 cents per lb. against 0·6 cent formerly; and rods over 4 cent per lb. in value, ¾ cent per lb.

On railway and other engineering material, the new American duties are:—Wheels—whether iron or steel, or whether wholly or partly finished—and tires, 1¼ cent per pound, as against 1¾ cents; axles, or parts thereof, 1½ cent. per pound, against 2 cents formerly; and forgings for locomotives, steam engines, or vessels, 1·2 cents per pound, against 1·8 cent per pound. Other iron or steel forgings, of whatever shape or in whatever stage of manufacture, not specially provided for in the Act, are rated at 1½ cents per pound, as against 2 3 cents per pound, always supposing that this charge does not amount to less than a 35 per cent. *ad valorem* duty. Boiler or other tubes are to be now charged 25 per cent. *ad val.* against 2½ cents per pound, and chains of all kinds 30 per cent. *ad val.* against 45 per cent. Castings not forming finished parts of machinery, and not otherwise specially provided, are rated at 0 8 cent per pound.

Interesting reference to a scheme of profit-sharing tried some time ago at Messrs. Tangyes' engineering works is made in a report which has lately been issued from the Labour Department of the Board of Trade. In October, 1883, the firm—who then employed about 1500 hands—introduced a profit-sharing scheme, by giving some of their men bonds for £50, current for one year and issued annually, entitling the holders if continuously in their service during the year, to receive interest "at the same rate per cent. per annum as the rate per cent. per annum declared by the company on their ordinary share capital for the year." If the holder of a bond died before the end of the year, his family became entitled to receive the principal sum secured thereby. After a time it was thought that these arrangements involved an undue degree of publicity in regard to the affairs of the firm, which is a private company, and it was decided that as from July 1, 1889, the bonds should bear a fixed rate of interest—five per cent. Thus profit-sharing was, after a few years' trial, abandoned.

A scheme of profit-sharing which is still in existence at the Spring Vale Furnaces, Wolverhampton, of Sir A. Hickman, M.P., was commenced in 1891, and has reference to about five hundred men. The amount distributed—as bonus—is a fixed percentage of the profits; no interest on capital is charged. At the end of the year the amount is divided in proportion to the wages earned between all the men who have worked during the whole year. The bonus is paid in cash. At the same time a bank was started, in which the men were invited to deposit, 5 per cent. per annum interest being paid on all amounts remaining at least a month. The average ratio of the bonus paid in 1892 and 1893 to wages has been 2·7 per cent. In regard to the results of the adoption of profit-sharing, Sir A. Hickman writes:—"I cannot say that there has been any perceptible result. On the whole, it is considered that as yet the experiment has not been fully tried."

The dispute with the surfacemen and the boys in the North Staffordshire coal trade is practically over, a result due to the conciliatory spirit exhibited by the Midland Coal, Coke, and Iron Company, who employ between 2000 and 3000 hands, and whose works have been closed for some weeks.

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester.*—A decided improvement has come over the iron market here, and during the past week or so buyers have been showing much more anxiety to place orders, with the result that a considerable weight of business has been put through, chiefly in pig iron, and makers have been in a position to secure better prices than have been ruling for some time past. Whether this improvement is of a permanent character remains, however, to be seen; there is still no indication that the actual requirements of consumers have increased in proportion to the larger volume of business put through, and perhaps to some extent the greater weight of buying is to be explained by anticipations that the revised American tariff, by stimulating activity in other industries, may indirectly help to give a stronger tone to the iron market rather than any present really reviving activity in the iron trade itself. Consumers and merchants have, no doubt, come to the conclusion that there is little or no probability of prices touching any lower point than has been reached recently, so that even the remotest prospect of outside influences tending to strengthen the position of makers would be sufficient to bring forward orders and contracts which have been held in abeyance; and this might sufficiently account for the extra weight of buying that has been going on during the past week or so. Any improvement so far has scarcely been felt outside the increased demand for pig iron; finished iron makers do not report any larger volume of business doing, and except that the prospect of having to pay more for raw material is necessarily compelling them to take a firmer stand with regard to the prices of finished iron, it can scarcely be said that in this branch of trade the position has materially altered. The steel trade also remains without any appreciable change, and very low prices continue to rule, both for raw and manufactured material.

The Manchester Iron Exchange on Tuesday scarcely brought together an average attendance, many of the usual representatives being away at the Brussels meeting of the Iron and Steel Institute. There was, however, a decidedly improved tone throughout the market, and in pig iron especially a considerably increased weight of business was reported. The tendency towards a stronger tone in prices for pig iron, to which I referred last week, has evidently brought forward previously hesitating buyers, and during the last few days more anxiety has been shown to settle renewals of contracts which had been held in abeyance, with the result that instead of the persistent hanging back and pressure on the part of buyers for further concessions upon quoted rates, makers have been enabled to secure slight advances upon the sales they have made. Lancashire makers, who have all along been considerably above the market as compared with the quotations for low-priced district brands offering here, have not, so far, made any quotable change in their list rates, but they are less disposed to meet buyers with concessions, and are firm at about 40s. for forge to 42s. for foundry, less 2½, at the works. Lincolnshire makers, who have been by far the lowest sellers in the market, having secured a moderate amount of orders at advances of quite 6d. on the prices they were prepared to accept a week or so back, are now holding out for an advance of fully 1s. per ton; and although this advance has scarcely as yet been established by actual transactions of any moment at the maximum figures, they are mostly now firm in quoting 39s. for forge to 40s. for foundry, net cash, delivered Manchester. In Derbyshire iron there has also been a strong upward move, foundry brands having been advanced in some case 1s. and in others 2s. per ton, quotations being now about 45s. and 46s. net cash delivered Manchester. It is reported that at one of the Derbyshire pig iron works, furnaces have been put on eight hours' shifts, which it is estimated will increase the cost of production something like 1s. per ton, and it is expected that other works in the district will have to follow suit, so that this in itself must still further tend to enhance the price of Derbyshire brands. With regard to outside brands offering here, makers of good named foundry Middlesbrough have put their quotations up to 45s. net cash, delivered Manchester. Of Scotch iron there is so little offering in the market that it is scarcely possible to obtain really definite quotations, but it would be difficult to place orders for Eglinton at under about 48s. net prompt cash, delivered at the Lancashire ports.

No very material change can be reported with regard to the position in the finished iron trade. Perhaps here and there a little more buying has been going on, but makers still report only a limited weight of business coming forward, and forges continue short of orders, four days per week being about the average that most of them are working. In view, however, of the upward move in raw material, makers are showing a tendency to harden up in their prices, and although there is no quotable change, £5 7s. 6d. to £5 10s. would now represent the minimum figure for Lancashire and North Staffordshire bars, delivered in the Manchester district. Other descriptions of finished iron remain much as last reported, Lancashire and Staffordshire sheets averaging £7 to £7 5s.; Lancashire hoops, £5 17s. 6d. for random, and £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

In the steel trade, also, the position remains much as last reported, except that hematites are showing a slight hardening, ordinary foundry hematites not now being quoted under 53s., less 2½ delivered in this district; but ordinary basic billets do not average more than about £4 net cash, and steel boiler plates could be bought readily at £6 5s. to £6 7s. 6d. delivered in this district.

In the metal market the decided upward movement in raw material has brought forward more inquiry for manufactured goods, in anticipation of some advance in list rates which has since been announced by makers to the extent of ½d. per lb. on recent list quotations.

The engineering industries throughout this district continue generally but very indifferently off for work. Here and there orders are reported to be coming forward more freely, but this does not represent any improvement of a general character, and the outlook for the future can scarcely be said to show any really better prospect. The monthly report issued by the Steam Engine Makers' Society is not of quite so unsatisfactory a character as that of the Amalgamated Society of Engineers, to which I referred last week, but does not show any improvement as regards the returns of out-of-work members, which still represent about 5½ per cent. of the total membership in receipt of donation benefit. In the reports as to the condition of trade from the various districts, stationary engine builders throughout the principal Lancashire engineering centres are reported to be fairly off for orders, but other branches of the engineering trade are returned as only very quiet, with no present indication of any reviving activity.

The coal trade throughout Lancashire continues in a very depressed condition, and but that the protracted strike of miners in Scotland has necessitated a considerable weight of both round coal and engine fuel being purchased in this district to meet requirements of consumers in Scotland, the position would have been about as unsatisfactory as could well be imagined. So far as local requirements are concerned, these would consequently have sufficed to keep pits going half time, and even with the extra demand for coal and fuel to be sent into Scotland, four days per week represents the full average that the collieries are working. The better qualities of round coal are a complete drug upon the market, and there is a good deal of underselling to clear away stocks that accumulate, but the average quoted prices remain at about 11s. for best Wigan Arley, 10s. for Pemberton 4ft. and seconds Arley, and about 8s. for the lower qualities of round coal, suitable for house-fire purposes. Local requirements for iron-making, steam, and general manufacturing purposes, also continue very limited; but in steam coal and engine fuel a good deal of the surplus supplies, which would otherwise have been thrown upon the market, are being sent away either by rail or shipment to Scotland, and this is helping somewhat to steady prices, although these are extremely low—not averaging more than 7s. to 7s. 6d. for steam and forge coals, 3s. 9d. to 4s. 3d. for common engine fuel, 4s. 9d. to 5s. 3d. for the medium qualities, with some of the best descriptions of engine fuel quoted at 5s. 9d. to 6s. 3d. per ton, at the pit mouth.

In the shipping trade business continues fairly active, largely, however, on account of shipments to Scotland, but there is also more doing for Ireland, Lancashire colliery owners being now in a position to regain a good deal of the business which was lost during the strike last year, and then went into the hands of the Scotch coalowners. Prices, however, are not more than maintained at late rates, common round coals for steam purposes not averaging more than 8s. 9d. to 9s. and engine classes of fuel 5s. 6d. to 6s. 9d. per ton delivered at the ports on the Mersey.

*Barrow.*—The pig iron trade, so far as hematites are concerned, is depressed to a greater degree than has been known for years. Makers of iron complain about the scarcity of orders on foreign account, and there is very little doing with home buyers. Were it not for the local demand, business would be almost nil. Prices are easy at 43s. 5d. net cash sellers, and 43s. 4d. buyers. Makers quote 44s. to 45s. per ton for mixed Bessemer numbers net f.o.b. They have only 33 out of 75 furnaces in blast. Last year there were 35 furnaces in blast.

Iron ore is more depressed than ever, as the consumption in the district is smaller, and there are still only small consignments going to Scotland. Eight shillings and sixpence is still the value of ordinary sorts, but 12s. to 14s. is the price for the best qualities net at mines.

Steel makers are short of orders in all branches save that of ship plates, and no new orders of moment have been booked for plates lately, and there are very few in the market, either for heavy or light sections. Billets and hoops are quiet, and nothing is doing in slabs, wire rods or blooms, while merchant steel generally is very quiet. Tin-plate bars give promise of a better market, now that the American tariff has been amended, and it is anticipated there will be a fairly active autumn and winter's trade in this department.

The shipbuilding and marine engineering trades are busy, chiefly on Admiralty work. No new orders are, however, reported. The demand for ordinary steam marine is very quiet. Repair orders are receiving some attention, and other orders are expected. The Fleetwood and Belfast Line are in want of another fast twin screw steamer.

The coal and coke trades are very quiet, but although supplies are adequate, prices are firm; 17s. is still the quotation for East Coast coke at West Coast furnaces.

The general engineering, ironfounding, and boiler-making trades are very quiet.

The trade of Barrow generally is depressed, although shipbuilders are busy. This is the only industry in the town which is busy.

The shipping trade remains very quiet. Exports of pig iron and steel from West Coast ports during the week have represented 13,281 tons. Last year in the same week they reached 22,981 tons, a decrease of 9703 tons. The aggregate shipments to date represent 486,289 tons, compared with 498,630 tons in the corresponding period of last year; a decrease of 12,341 tons. Freights are low and unremunerative.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

The reduction of wages has followed the severe depression in trade so far at least as coal is concerned. Languor affects all collieries, but most materially those producing the qualities required by gas companies and the pits employed in the household sorts. Supplies of the latter are very largely in excess of the demand. This, of course, has the inevitable effect of causing buyers to hold off, in the belief that by delay they will get what they require on easier terms. Coalowners, on the other hand, are determined that values are as low as they can be, simply because they have no possibility of still further reducing the cost of production. They are not likely to modify their present attitude, and, on the whole, they have the best of the struggle, as prices are fairly well maintained.

Business is affected somewhat by the action of the pit lads, who stoutly resist the reduction of 10 per cent. imposed under the Conciliation Board arrangement. Their argument is not unreasonable. They say they did not get the 40 per cent. advance, and therefore they have no 10 per cent. to give back. Consequently, as pits cannot be worked without boy labour, the lads are giving several collieries "play" when the colliers neither expected nor desired it. They could scarcely have taken a less favourable season for their action, for the summer demand is now so light that a pit closed here and there is of little account in the general supply. At present the tonnage to London is decidedly below the average. Silkstone house coal is quoted at from 9s. 6d. to 11s. per ton; Barnsley softs from 8s. 6d. to 10s. per ton; Flockton, 8s. 6d. to 9s. 6d. per ton. Although the season is now well advanced, steam coal is steady, a very heavy tonnage being sent to Hull and the other Humber ports. Barnsley hards are from 7s. 9d. to 8s. 6d. per ton; other qualities 9d. to 6d. per ton less. Manufacturing fuel is in full supply, but light request, thus reflecting the poor business at present being done in the iron and steel trade, as well as in the mills of the textile districts, particularly in the localities where cotton is the staple production. Slacks cannot command more than from 3s. 6d. to 5s. per ton; smudge and small coal very dull; coke in quiet request at from 9s. to 11s. per ton. Coalowners find it at present more profitable to convert their small coal into coke, for which they find a fairly good market in Lincolnshire and Northamptonshire for smelting purposes. A considerable quantity of coal is now being shipped from the Yorkshire pits to Scotland.

In the iron and steel industries, although the business done is far from adequate, there are signs of movement. Railway material, chiefly in rolling stock, is now being freely ordered for the home companies and for India. Large "lines" for railway carriages, wagons, locomotives, &c., have recently been given out, and others are certain to be placed soon. These orders mean a good demand for buffers, springs, wheels, tires, and axles, as well as for the various steel parts required for engines. Amongst the companies in the market with good orders is the Midland, who are in need of further engines, wagons, and carriages.

The decision of the American Senate, embodied in their Tariff Bill accepted by the House of Representatives, to admit iron ore free of duty, has had the effect of stiffening quotations for hematites, which are now at slightly increased quotations, viz., 51s. 6d. to 53s. per ton. This is an advance of 6d. per ton, but it would excite no surprise if before these lines are published a further rise took place. The fact is that this country does not produce sufficient ore for her own requirements, to meet which Spain and Sweden are laid under contribution to the extent of one-third. These are the sources from which the United States will no doubt draw what they want. Our manufacturers do not regard this feature of the new Tariff arrangements as an unmixed benefit. The abolition of duty on raw material, many of them say, will cheapen and stimulate manufactures in the States, and make competition with our people still keener. The presence of American buyers in the Spanish and Swedish markets will also cause English iron and steel makers to pay more for their raw material.

The new American Tariff is received favourably in the quarters chiefly engaged in the lighter industries. Cutlery manufacturers, in particular, are thankful the uncertainty is over. The new duties will not very greatly benefit this city, but they put an end to the waiting game which has practically paralysed all trade. It is conceded that Sheffield can never again have the business it once enjoyed with the States, for the excellent reason that the Americans are now quite able to supply themselves in many classes of goods they once obtained exclusively from this city. For the balance of work that is left, the Germans are keen competitors. In the superior grades of articles, both in carvers and pen and pocket cutlery, the chief trade will still be in Sheffield-made productions.

An improvement is reported in the local engineering branches, largely attributable to increased enterprise in invention. Some important patents, of which more may be heard soon, have recently been taken out by Sheffield engineering firms. There is a slight, but very slight, change for the better in the demand for machinery. In chilled irons the American monopoly is reported to have been met and broken by English makers, who now command the continental market.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

The improvement in trade which was reported last week has been even more pronounced this week, and a very substantial amount of business has been done, not only speculators but also consumers buying pig iron freely, as they believe that the upward movement will continue, for it appears to be general, the metal markets, the stock exchange, and the money market all exhibiting more favourable features, and therefore the likelihood is greater that the revival will be maintained. Good orders have within the last few days been booked for Cleveland pig iron, chiefly of No. 3 quality, and the fact that exports so far this month have been poor, and that the stocks will probably show a greater increase even than last month, has no effect in preventing the rise in prices. Under ordinary circumstances this would have a depressing effect upon the market, but the activity that has been shown in buying counteracts this, and no one pays any attention to the present increasing stocks, as the prospects appear so favourable. Speculators seem to regard the future of the iron trade as encouraging, as they have been operating rather freely, and this is significant when it is remembered that it is a long period since they would have anything to do with warrants. Consumers have been brought out, and have apparently given up their policy of buying from hand to mouth only, but both at home and abroad they are anxious to arrange for iron for forward as well as prompt delivery. The revival will be helped forward by the autumn demand which is now setting in.

Another very hopeful feature which cannot but have a good influence upon trade is that the strikes which have for so long seriously hampered business are about to come to an end. It is believed that the Scotch strike cannot last more than a week or two longer, and the strike of moulders and pattern makers in the North of England, which has been in progress for nearly twenty-four weeks, and has thrown out of work fully 20,000 men engaged in other branches of trade, will be ended in a few days in all probability, because the men have at last agreed to the proposal of the employers that the dispute shall be submitted to arbitration, the award to take effect from the day the men resume work. Each side is to choose an arbitator, and the two arbitrators are to choose a referee, who shall be a barrister or a County Court judge. The moulders, it will be remembered, originally came out because the employers declined to give them an advance of 3s. 6d. per week, on the ground that, though trade had become brisker, the value of the product had not increased. Subsequently the men modified their claim, making it 2s. per week advance, and since then the masters have claimed a reduction from the wages that ruled when the strike began, trade having changed considerably for the worse of late, chiefly through the action of the men in thus stopping work. The men were rather averse to the arbitrators being commissioned to consider anything but their claim, as that was the cause of the strike; but they have now admitted the right of the arbitrators to adjudicate upon a reduction, seeing that the circumstances of the trade have changed so much. The men are to return to work at once, and the award is to date from the time when operations are resumed. The strike has been a most disastrous one for the district, as it has affected so many other branches of trade, and punished very severely about ten times as many workmen as those actually engaged in the strike. We may now look for the early re-opening of the shipyards which have been closed, and the consumption of steel plates and angles will be increased, as well as that of hematite pig iron. A number of engineering works have also been idle for lack of castings, and these will be able soon to recommence operations.

Sales of No. 3 Cleveland pig iron have been large this week, and have been mostly made at 36s. 3d. per ton for prompt f.o.b. delivery, and some business has been done at 36s. 6d., this being 1s. advance upon the price that ruled for some weeks prior to last week. A considerable number of orders have been placed for delivery up to the end of the year at 36s. 4½d., but producers are now chary about selling for forward delivery. No. 3 Cleveland pig is said to be scarce in makers' hands, and that this is so is evident from the fact that a considerable quantity has had to be withdrawn from the public warrant stores. There is, however, likely to be an increase in stocks reported for the month, but it will be in the commoner qualities, and not in No. 3. Forge qualities are much more plentiful than they were; they have been more largely produced during the last fortnight, because since the blast furnacemen took their holiday on the 11th inst. the furnaces have worked badly, producing more than their usual proportion of forge iron, and this has been rather a drug upon the market, and the advance in them has only been 6d. instead of 1s., as in No. 3, grey forge being offered at 34s. 3d. For No. 4 foundry, 35s. is the figure. The warrant market has been brisker this week than for a long season, and in prices there have been considerable fluctuations, as much as 6d. in a day. Cleveland ordinary warrants have been at 36s. 6d. cash, and closed on Wednesday at that. The improvement in hematite pig iron has been very slight so far—hardly 3d. per ton, but will be greater when the moulders' strike is over, and the shipyards and steelworks are able to resume operations fully. Mixed numbers of East Coast hematite pig can still be bought at 43s. per ton, f.o.b., and makers are able to buy good Rubio ore at 11s. 9d. per ton delivered on Tees-side, though 12s. is the general figure.

In finished iron and steel business is improving a little, but production is further curtailed this week, because most of the mills and forges on Tees-side are idle, the workmen being generally given a holiday during the Stockton race week. Orders are more freely distributed to manufacturers, and the tendency of prices is upwards. Steel ship plates are quoted £5; steel boiler plates, £6; steel ship angles, £4 15s.; iron ship plates, £4 15s.; iron boiler plates, £5 15s.; iron ship angles, £4 12s. 6d.; iron engineering angles, £4 17s. 6d.; common iron bars, £4 17s. 6d., all less 2½ per cent. and f.o.t. The demand for rails and railway materials is most unsatisfactory, and it is years since the export of rails from the North of England was so small as it is now. The competition is extremely keen, and it is not likely that the stoppage of the Darlington Works will make the situation any more tolerable for those who are keeping on, because there are so many establishments at home and abroad short of orders. Heavy steel rails can be bought at £3 10s. net at works. The demand for steel billets is somewhas stronger, and exports of these to the tin-plate manufacturers of South Wales are fair. A good amount of bridge work is being turned out, but there is not much doing in steel girders for building purposes.

The coal trade in this district is decidedly active, especially in the steam coal branch, and heavy shipments are made to the Continent, where merchants are availing themselves of the low freights to lay in stocks. The freights to many ports are the lowest ever known, and shipowners cannot but be great losers when accepting them. Best Northumberland steam coal is quoted 11s. per ton f.o.b. Durham coke of good quality cannot well be had under 12s. 6d. per ton, delivered equal to Middlesbrough, or 14s. 6d. f.o.b. The death took place this week of Mr. John George Russell, of Shencliffe, near Durham, manager for many years for Messrs. Ferens and Love's collieries. Mr. Morrison, of the Newbattle Collieries, Dalkeith, has been appointed manager of the Cramlington collieries in succession of the late Mr. Shelton. The death is also announced of Mr. J. A. Haswell, for many years connected with the locomotive department of the North-Eastern Railway at Gateshead. He was one of the pupils of Robert Stephenson.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE pig iron market has been more active in the past week than for a considerable time previously. A good deal of speculation has taken place in warrants since the passing of the American Tariff Bill, and prices have steadily advanced. Scotch warrants have risen fully 1s. per ton, more than one-half of which has occurred this week. Business has been done in Scotch warrants from 42s. 8½d. to 43s. 4d. cash. Hematite has been done at 44s. 5d. to 44s. 6½d. Very little inquiry has arisen for Cleveland warrants, the consumption of this class of iron in Scotland just now being much curtailed by the stoppage of the ironworks.

The demand for makers' iron is quiet; but stocks are very light, and prices continue to advance. Gartsherrie, Eglinton, Carron, and Langloan pig iron are all unobtainable in the open market, and merchants decline to quote prices for these. G.M.B. f.o.b. at Glasgow, No. 1, is quoted 44s. 6d. per ton; No. 3, 43s.; Carnbroe, No. 1, 48s.; No. 3, 46s.; Monkland, No. 1, 47s.; No. 3, 43s.; Clyde, No. 1, 56s.; No. 3, 50s. 6d.; Summerlee, Nos. 1, 56s.; No. 3, 50s.; Calder, No. 1, 57s.; No. 3, 50s.; Coltness, No. 1, 57s.; No. 3, 52s.; Glengarnock at Ardrossan, No. 1, 51s. 6d.; No. 3, 48s.; Dalmellington at Ayr, No. 1, 50s. 6d.; No. 3, 46s.; Shotts at Leith, No. 1, 56s.; No. 3, 51s.

The shipments of pig iron from Scottish ports in the past week have been very light, amounting to only 1456 tons, compared with 4932 tons in the corresponding week of last year. There was despatched to the United States 25 tons, India, 28; Australia, 100; France, 10; Germany, 50; Holland, 485; Belgium, 20; Spain and Portugal, 60; China and Japan, 200; other countries, 170; and coastwise, 308, against 2118 in the same week last year.

One furnace having been put out at Coltness, there are two at these works left making ordinary iron and four at Shotts, these six being all that are blowing in Scotland. Some time must elapse before the output is materially increased.

The business in finished iron is of comparatively little importance. Makers are not in a position to book orders. In many cases their men would gladly be at work, but the miners' strike prevents them. The makers are not inclined, except in cases of absolute necessity, to keep their works going at a time when fuel is advancing, and when there is little chance of obtaining substantially higher rates for their products.

The shipments of iron and steel manufactures from Glasgow in the past week embraced sewing machines worth £6561; other machinery, £5061; steel goods, £4698, and miscellaneous iron goods, £10,970.

The steel works remain closed, and business, for forward delivery, has really scarcely any existence.

The coal trade is quiet. Colliery owners who had stocks to sell have in many instances had them cleared out, and home consumers are now largely dependent upon supplies from England, which now come to hand in considerable quantity, and are sold at fairly moderate prices. The shipping trade in coals shows no improvement. The shipments for the week amounted to 7653 tons at all the Scottish ports, compared with 170,977 tons in the corresponding week of last year. Prices of coals are somewhat higher.

At several of the collieries this week numbers of miners have been at work, and they have had to receive police protection from the crowds striving to molest them. Renewed efforts have been made in a semi-private way to bring about some arrangement of the strike, but these have all hitherto failed, the demands of the men being impossible of realisation. The strike has been continued for about nine weeks. In many places the men and their families have been reduced to the point of starvation. Subscriptions are freely given for their relief, but these prove quite inadequate. The general trade of the country is suffering severely from the strike.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE quietness which I noticed last week as characterising the steam coal trade continues, and prices are evidently slowly receding. The impression, however, on 'Change at Cardiff is that the lull is only a temporary one. House coal prices keep up well, and that is satisfactory, considering that we are nearing the time when contracts will come to the front; and if present quotations can be retained, there will not be much cause for complaint.

The latest quotations on 'Change, Cardiff, for steam coal are as follow:—Best steam, 11s. 3d. to 11s. 6d.; seconds, 10s. 9d. to 11s.; dry coal, 9s. 9d.; and small, 5s. 6d. to 6s. 3d. It was noticeable that best small coal on Monday touched 6s. 3d., but the next day fell to 6s. Best steam fell 3d. from Monday to Wednesday.

Best house coal is still selling at 12s. 6d. to 13s., but this is for specially selected; at present good house coal can be obtained for 10s. 9d. to 11s., and No. 3 Rhondda for 10s. 6d.; brush, 8s. 6d. to 8s. 9d.; small, 6s. 6d. to 6s. 9d.; No. 2 Rhondda, 8s. 6d. to 8s. 9d.; through, 7s. to 7s. 3d.; small, 5s. to 5s. 3d. Coke prices keep up fairly well, and I note that though Cyfarthfa is now making a great quantity with admirable appliances for turning out the best kind, there is still a percentage of Dinas Main coke used there. Rhymney cokes and Llwynypia are well to the front. Latest quotations are a slight improvement upon those of last week. Cardiff: furnace, 15s. to 16s. f.o.b.; foundry, 17s. to 17s. 6d.; and special foundry, 20s. to 21s.

Pitwood market is improving, and great quantities are being sent up to the principal collieries. Few have any idea in the outside world of the large quantities used, and the prominent figure they make on the cost sheet. Still, in no case have I heard of the adoption as in some North of England collieries, of steel pit props. The complaint is that they are too rigid, and have not the "giving" character of timber. This is or was also one of the objections to the substitution of steel for wood sleepers, though I see that Bombay is in the market for large quantities, which are being turned out at Dowlais Works, Cardiff.

The present quotation for pitwood is 15s. 9d. for ordinary ex-ship. There is no material alteration for patent fuel, which is in moderate demand Cardiff. Swansea dispatched 10,000 tons last week. In iron and steel there is also only a moderate demand, steel bar being the principal, and colliery rails. Judging from the quantity of iron ore coming in, ironmasters have still faith in the future. Not only are large consignments being received of Bilbao, Tafna, Garucha and Porman, but a fair quantity of Cumberland ore, which is specially rich, with a percentage of 58 per cent. This contrasts well with Bilbao, with its average of 48 to 50 per cent. Best Rubio is at 11s.; Tafna and Garucha at 10s. 6d., and Porman, 9s. 9d. to 10s. per ton, c.i.f., Newport or Cardiff.

The change which has taken place in the ironworks of Wales was forcibly brought to mind by the remark of an old inhabitant of the district this week, who remembered the time when four thousand iron ore miners were employed by Cyfarthfa alone, and now, though a small quantity is worked from the coal pits, there is not a single iron miner specially employed, and all the old mine pits are closed.

The leading quotations this week for iron and steel are little if any different to those of last week. Heavy sections, steel rails, are at £3 15s., and light £4 7s. 6d. to £4 10s. Bessemer steel bars are at £3 18s. 6d. I have had an opportunity this week of seeing some remarkably fine samples, but unfortunately the capacity of make is a good deal beyond the demand. Furnaces here and there idle, and blank days are common matters in the district. Blaenavon works, Cyfarthfa, Dowlais, Ebbw Vale, and others are replenishing their iron ore stocks. Pig stocks are large in several localities.

The chief export of late has been iron to Santos, under the heading of "2086 pieces." If it had been tons it would have been more up to the desire of ironmasters and shippers.

In the Briton Ferry district sixteen mills and the finishing departments have been fully employed, and the make of pig is quite up to the average. Notices of temporary stoppage are up at some of the works while the canal is being repaired. I am glad to note that the Earlswood Tin-plate Company is pushing on the completion of their works, and a start next week is expected.

Generally there is little change in the tin-plate trade. On 'Change Swansea the impression is that an alteration for the better will begin to show itself in the middle of next month. Make and shipment have been of late fairly equal. Last week at Swansea 47,510 boxes were received from works, and 48,480 boxes shipped. Vessels are coming in freely to load for America, Canada, Hamburg, Genoa and Leghorn. The stock now held at Swansea is 286,908 boxes. Prices are the same, Siemens, 10s. 9d. to 10s. 11d.; Bessemer, from 10s. 4½d. to 10s. 9d. f.o.b.; wasters, from 9s. 6d. These are the lowest figures prevailing for ordinary cokes, but the Wilson Tariff Bill, the passing of which has given a good deal of satisfaction, must shortly improve matters.

The Rhondda and Swansea Bay line, through to Swansea, is to be opened on the 1st October. The Neath Bridge was swung for the first time on Saturday, and is stated to have worked most satisfactorily.

Trouble would appear to be looming in the coal trade. Mr. Abraham, M.P., "Mabon," is stated to have written a letter read at an Aberdare meeting on Saturday, in which the hon. member intimates "that if the employers persisted in maintaining their uncalled for and intolerable position in refusing check weighers to tender evidence, when selected by the workmen, he could not, notwithstanding the pain it gave him, see his way to promote the maintenance of the sliding scale at the sacrifice of principle and right." At the Aberdare meeting the subject in dispute was discussed at great length, and it was decided to ascertain by ballot the opinion of the colliers generally.

I may add that the miners' representatives are not altogether unanimous in supporting "Mabon," so it is to be hoped that after a free discussion the storm will blow over.

The Albion is again in full work. The outcome of the explosion has been a good deal of discussion and experiment in regard of shot firing and the extension of an explosion by coal dust.

The men of No. 2 Pit, Llanbradach, are on strike. They demand 4s. 9d. per day plus the percentage, but the management is only prepared to pay 4s., or agree upon contract prices while opening the colliery, pending the identity of seam, and a fixed price list of all items of labour in the colliery.

On Monday the Vale of Glamorgan Railway was practically begun with the cutting of the sod, by Messrs. Butler and Baker, contractors. The viaduct in Porthkerry Park is to be a fine engineering achievement. It is to contain seventeen arches have an entire length of 1000ft., and be 100ft. high.

The electric lighting of Monmouth is to be carried out.

Taff Vale receipts last week were £15,647 as compared with £5945 for the corresponding week last year, when the colliers' strike was on, and but for prompt action of the authorities the whole district would have been plunged into a ruinous condition.

Latest Swansea quotations show an improvement on pig iron. Glasgow warrants are at 43s. 4d.; hematite, 44s. 5½d.; Welsh bars from £5; sheet iron, £6 to £6 10s.; steel, £6 5s. to £6 10s. Block tin shows an advance of £3 10s. upon the week. Prices are now £71 10s. to £71 15s. Anthracite maintains the same figures, 8s. 9d. to 12s. 6d., according to quality.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

A FAIRLY satisfactory business has been doing in iron and steel this week, and the reports coming in from the different markets are a trifle more cheering. Prices remain pretty firm all round. The state of the Silesian iron industry is much the same as was reported in former letters. Some of the blast furnace works remain tolerably well employed, while others have had to limit their production considerably, during the last month; the Gleiwitz works, for instance, has blown out one blast furnace which had been put on ordinary pig in the spring, when the demand for that sort had been specially brisk. At the rolling mills a fair activity is generally maintained, the demand for sheets being remarkably good; plates, on the other hand, are but very weakly called for. Steel makers still complain of the scarcity of orders for rails, and quotations are extremely depressed, with little or no chance for an improvement. Nails and rivets are in poor request.

The situation of the Austro-Hungarian iron market continues to be quite satisfactory. Upon the week a brisk demand has been experienced in almost all branches of the pig iron trade, and in the manufactured iron department, likewise, a very lively tone prevails. The steel trade is, if anything, even a trifle more brisk than in former weeks. List rates for both raw and finished iron show little or no change since previous reports, and are, all things considered, fairly remunerative.

Pretty satisfactory accounts are given of the condition of French iron trade, and though, on the whole, few large purchases are made, producers as well as dealers show much firmness, and the quiet but confident tone repeatedly noted has been well maintained. French import and export in coke and iron was, for the first two quarters of present year, as under:—

| | Import. | | Export. | |
|---|---|---|---|---|
| | 1894. | 1893. | 1894. | 1893. |
| | t. | t. | t. | t. |
| Coke | 742.580 | 689,908 | 21,660 | 25,038 |
| Pig iron | 32,938 | 46,627 | 55,862 | 49,431 |
| Malleable iron | 9,771 | 9,793 | 10,589 | 10,668 |
| Steel | 2,927 | 2,776 | 6,556 | 5,270 |

Only a very slow inquiry for either raw or manufactured iron is reported from the Belgian iron market. As regards pig iron the tone, taking it all through, was rather easier; manufactured iron makers, as a rule, report that branch of trade as only in a very unsatisfactory condition, and the works that are largely dependent upon export are very short of orders. Changes in quotations cannot be quoted; indeed, a further decrease is almost impossible, as makers in most cases are working their mills at a loss, and many of them would, therefore, prefer a general stoppage to further reductions in prices.

Belgian trade in iron and steel, during the first two quarters of the present year, was:—

| | Import. | | Export. | |
|---|---|---|---|---|
| | 1894. | 1893. | 1894. | 1893. |
| | t. | t. | t. | t. |
| Iron ore | 929,028 | 869,740 | 106,604 | 87,070 |
| Steel | 9,178 | 7,041 | 354 | 271 |
| Steel bars | 195 | 242 | 9,328 | 3,253 |
| Steel rails | 188 | 284 | 32,301 | 15,117 |
| Steel manufactured goods | 5,426 | 3,847 | 11,389 | 8,189 |
| Pig iron | 119,684 | 58,309 | 6,978 | 10,591 |
| Scrap iron | 12,768 | 9,625 | 4,281 | 4,014 |
| Iron wire | 3,663 | 2,966 | 285 | 420 |
| Girders | 153 | 100 | 19,087 | 27,431 |

It is characteristic of the Rhenish-Westphalian iron business that, in spite of sufficient, and in some instances even brisk, employment, prices do not show the slightest inclination to rise. In the iron ore trade only a moderate demand is coming forward, but quotations are firmly maintained. For spathose iron ore M. 7 to 7·90 p.t. has been paid last week, while roasted ditto fetches M. 11 to 11·50 p.t. at mines. Inferior qualities are paid with M. 9 to 11·20 p.t. net at mines. A very slow business is still being reported in the pig iron trade. Spiegeleisen, which has been in somewhat better inquiry this week than last, still stands at M. 52 p.t.; while Rhenish-Westphalian forge pig No. 1 is in fair request at M. 46 to 47 p.t., and No. 2 is paid with M. 40 p.t. Hematite costs M. 63 p.t.; foundry pig No. 1, M. 63, No. 3, M. 54 p.t. Basic, though very quiet at the present moment, firmly maintains the old price of M. 45 p.t. German Bessemer is quoted M. 49 to 50 p.t. Luxemburg forge pig is to be had at 48 f. p.t., free Luxemburg. There is very little to note in connection with the malleable iron trade; bars are in tolerably good call and so are hoops, but girders have experienced some neglect, and the prices for that article are, therefore, rather inclined to weakness. Good activity is maintained at the plate mills, the heavier sorts of plates being in specially good request. The demand for sheets continues lively, and some of the mills will be well engaged up to end of the year; but prices are, if possible, worse than ever, having shown a strong tendency to decrease lately. The requirements for gas and waterworks having been exceptionally large this year, the tube mills are, as a rule, in vigorous occupation; pretty good orders have already been booked for next year, so that this branch of industry is well off, at least so far as employment is concerned. At a late tendering for fish-plates, M. 108.10 p.t., was the lowest offer, others ranging between M. 110 and 127 p.t. Latest list quotations, per ton at works, are as under:—Good merchant bars, M. 110; rivet iron, M. 125 to 128; angles, M. 120; girders, M. 90 to 95; hoops, M. 113 to 118; billets in basic and Bessemer, M. 81; heavy plates for boiler-making purposes, M. 150; tank, do., M. 130 to 135; steel plates, M. 125; tank do., M. 115 to 120; sheets, M. 125 to M. 135. Siegen thin sheets, M. 130. Iron wire rods, common quality, M. 115 to 120; drawn wire in iron or steel, M. 105 to 120; wire nails, M. 125; rivets, M. 150; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 115; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230; light section rails, M. 95.

The Saar mines have produced 537,545 t. of coals in July of the present year, and sold 501,195 t. Production for the same month last year was 484,070 t., while the consumption amounted to 462,305 t.

## AMERICAN NOTES.

(*From our own Correspondent.*)

New York, August 16th.

The salient features of the American markets are moderate stocks, guarded production and low prices. Everything betokens an increase in production. The termination of the tariff deadlock is hailed with delight. There will be an early improvement, because of the low condition of stocks everywhere. Unfavourable crop reports induced a spurt in speculation. Railroad traffic continues without any improvement whatever in a general way. Prices of material of all kinds are low. An occasional effort to push speculation fails. While the banks have more money than they can lend, the directors are more conservative than ever, and only the best paper meets with favour. The iron trade is somewhat better, but even with the increase to 110,000 tons per week, only about one-half capacity is employed. Steel rails are dull at 24 dols., steel billets 19 dols., with 18 dols. offered for late deliveries. Work is getting better in the foundries and machine shops. A foundation has been laid for a general and permanent improvement in internal trade. Manufacturers will be anxious to take advantage of the low range of prices on the first sign of a genuine advance in business.

## LAUNCHES AND TRIAL TRIPS.

On the 16th Messrs. R. Craggs and Sons launched from their Middlesbrough yard a steel screw steamer, of the following dimensions:—Length, 178ft.; breadth, 28ft.; depth moulded, 14ft. 2½in. She will be fitted with triple expansion engines, by Messrs. Westgarth, English, and Co., of Middlesbrough, having cylinders 14in., 22½in., 37in. by 27in. stroke, with a boiler 12ft. by 10ft. working at a pressure of 160 lb. The vessel has been built to the order of Messrs. Whiteway and Ball, of Torquay, and will take the highest class at Lloyd's.

On Saturday afternoon Messrs. R. Craggs and Sons launched from their Middlesbrough yard a vessel having some novel features, built to the order of Mr. Joseph Constant, of London, on account of Messrs. William Cory and Son. The vessel is fitted as a sea-going towing craft, to carry 350 tons deadweight. She is entirely self-trimming, and the dimensions are specially suited for delivering cargoes at certain wharves in the river Thames. Her dimensions are as follows:—130ft. by 21ft. by 9ft. 8in. moulded. On leaving the ways she was named the Coral.

A few days since the s.s. Bulgaria, the second steamer built by Wigham, Richardson, and Co., at their Neptune Works, for the Bulgarian Steam Navigation Company, went to sea for a very successful trial trip off the river Tyne. The Bulgaria is a yacht-like steel screw steamer, 250ft. in length by 33½ft. beam, rigged as a two-masted schooner, and has very elegantly finished accommodation for first and second-class passengers. During the trial trip a high speed was obtained, and the engines worked without the slightest hitch of any kind, giving complete satisfaction to both the builders and the representatives of the owners.

The new steamer Louth, built by Messrs. Blackwood and Gordon, Glasgow, for the City of Dublin Steampacket Company, made its official trial trip last week on the Clyde. The vessel measures 260ft. by 34ft. by 16ft. 9in. The first-class saloon will accommodate seventy passengers. The engines are of the triple-expansion type, of 2750 indicated horse-power. The space allotted to cattle is large, enabling 500 head of cattle to be carried, and the ventilation is worked on an automatic principle, giving a current of air in stormy weather as well as in good. Electric light is used, supplied by Siemens Bros. and Co. The lamps number eighty-two, including those used for the cattle holds. Large electric reflectors are erected for cargo and cattle unloading. The holds are fitted with bull's-eye globes, to stand roughest usage. The Louth's tests extended over a six hours' run, and the first run she did the distance, 14½ knots, in fifty-seven minutes, being loaded with 700 tons deadweight.

On the 20th inst., Messrs. Cumming and Ellis, Inverkeithing, launched a steel sailing barquentine, 145ft. by 27ft. by 14ft., designed to carry 600 tons deadweight on a 12ft. 6in. draught. The vessel has been built for London owners, and is intended for their trade from St. Petersburg to Vladivostock. She is classed 100 A1 at Lloyd's, and built with double bottom containing 108 tons water ballast. The double bottom is divided into three separate spaces, which can be filled independently, and as the vessel is intended for the carrying of a general cargo, little attention requires to be paid to the stowage, as the vessel will be trimmed by the filling or emptying of the different compartments in the double bottom. A steam winch and donkey boiler are fitted on the main deck, and the vessel carries a steam launch, which is to be used for towing in light or head winds. The vessel has a full poop and monkey forecastle. Accommodation for the captain is provided aft, while the crew are berthed in a deckhouse on the main deck. Poop deck and forecastle deck are of Oregon pine, the main deck being of iron.

The s.s. Aberdeen, which has been built and engined by Messrs. Fleming and Ferguson, Paisley, for the Government of Canada, for protection of the coast fisheries, &c., has recently completed a series of runs, and on the measured mile attained a mean speed of over 13 knots. She is fitted with electric light in cabin, holds, and on deck, and has also a powerful search light of the Admiralty pattern. The boilers, which are of the firm's water-tube type, with natural draught raised steam in one-fourth of the time allowed in ordinary tubular boilers, and when under full steam showed no signs of priming and almost no variation of water in the gauge glasses. The boilers and machinery during the trials worked without hitch. At the trials there were present Mr. J. T. Milton, chief engineer, Lloyd's surveyors, London; James Mollison, chief engineer surveyor of Lloyd's, Glasgow; and W. T. Courtier-Dutton, representing the British Corporation for the Survey and Registry of Shipping. The Aberdeen has been built to the specifications and plans of Captain M. P. McElhinney, nautical adviser to the Government of Canada, who came over to be present at the trials, and during construction the vessel has been under the supervision of Messrs. NcNicholl and Co., Glasgow.

On Saturday afternoon Messrs. R. Napier and Sons launched from their shipbuilding yard at Govan, the steel screw steamer Nineveh, of about 4000 tons gross, built to the order of Messrs. Geo. Thomson and Co., of Aberdeen and London. The general dimensions of the vessel are: Length over all, 386ft.; breadth, 45ft.; depth, 32ft. The hull and machinery have been constructed under special survey to Lloyd's highest class, and modern appliances have been provided for the rapid handling of cargo. There is also an electric lighting installation, and refrigerating chambers for the transport of frozen meat, &c. Accommodation amidships has been provided for about fifty first-class passengers forward of the engines, and in order to obtain better light and ventilation, the dining saloon has been placed on the upper deck, a music saloon and smoking-room being on the promenade deck. The state-rooms are situated on the main deck. The 'tween decks have accommodation for a large number of third-class passengers, with separate entrances in a deckhouse aft. The captain and navigating staff have their quarters on the bridge deck beside the chart-room, the engineers' cabin being on the upper deck, near the engine-room. The machinery consists of a set of triple-expansion engines, capable of indicating 3000-horse power, designed to give the vessel a speed of 13 knots, with two double ended steel boilers for a working pressure of 160 lb. The vessel has a cut-water bow and figurehead, and a three-master's rig. Miss Muriel Thompson, daughter of the late Cornelius Thompson, cut the cord, and as the vessel moved down the ways Mrs. Duff Henderson named her the Nineveh. The machinery has been constructed at the builders, Lancefield Works. When completed, the Nineveh will be commanded by Captain Allan.

Messrs. Wm. Simons and Co., of Renfrew, launched from their yard, complete, the Percy Sanderson, the largest and most powerful hopper dredger afloat. It has been constructed to the order of the European Danube Commission, and will be employed principally in deepening the entrance to the Soulina mouth of the river Danube. It is of the stern well type, that is to say, instead of the bucket ladder being projected through the fore end of the vessel, it is adapted to dredge at the stern. This arrangement enables the vessel to encounter heavy seas more easily, and facilitates the steering and handling. The hull is constructed of steel to Lloyd's requirements, and the hopper compartments have a capacity for nearly 1300 tons of dredgings. Water ballast compartments are provided, and the hull is divided into ten watertight compartments. The buckets, which are of great lifting capacity, are capable of dredging to a depth of 35ft., a depth which is considered quite sufficient for the present requirements. The dimensions of this dredger are:—Length, 227ft.; breadth, 40ft.; depth, 17ft. Two sets of triple-expansion engines are provided for driving twin propellers; they also drive the dredging machinery, either set being capable of answering this purpose. Steam is derived from two mild steel boilers constructed to Lloyd's rules, for a working pressure of 160 lb. per square inch. The loaded speed of the dredger will be at least eight knots per hour. Powerful steam mooring appliances are provided at the bow and stern, also steam hoisting engines for raising and lowering the bucket ladder and the suction pipes. The hopper doors are lifted by steam. The dredger is lighted throughout by electricity. Besides the endless chain of buckets referred to on starboard side, there is fitted a powerful centrifugal sand dredging pump, fitted with suction pipes of 22in. diameter, driven direct by a pair of triple-expansion engines of 300 indicated horse-power; the suction pipe is also capable of dredging to a depth of 35ft. under the water line. This vessel has been constructed to the requirements of Sir Charles Hartley, of Westminster, and Mr. Charles Kubl, the resident engineer to the Commission, Mr. Wilson Wingate acting as inspecting engineer.

On Saturday a cargo steamer with passenger accommodation was launched from the Walker Shipbuilding Yard of Messrs. Sir W. G. Armstrong, Mitchell, and Co. The vessel is of the three type deck with poop, bridge, and forecastle. Her dimensions are:—376ft. by 47ft. by 30ft. 6in., and she is capable of carrying a large cargo on a moderate draught of water. Power is being provided for a speed of 12 knots. Lloyd's requirements for their highest class have been fulfilled. The propelling machinery is on the triple-expansion system, working at a pressure of 160 lb., and steam is supplied by three single-ended boilers, fitted with forced draught on Howden's system. The appliances for loading and discharging the vessel have been carried out in such a way as to secure the shortest possible delay in port. State-rooms are provided for about sixty first-class passengers. A dining saloon, capable of accommodating this number at one sitting, ladies' boudoir and library, and a commodious smoking-room are placed on deck. The vessel has been built to the order of the British and Colonial Steam Navigation Company, under the superintendence of Mr. H. A. B. Cole, representing the owners.

The s.s. Strathord went on her trial trip on the 21st inst. from Hartlepool. This vessel is a sister to the s.s. Strathness and s.s. Strathnairn, and is the third of the four steamers built by Messrs. Wm. Gray and Co. to the order of Messrs. Burrell and Sons, of Glasgow. She carries 6400 tons deadweight, and is 376ft. 6in. in length, with a breadth of 47ft. and depth of 29ft. 9in. Her engines have been supplied by the Central Marine Engine Works, and are of the triple-expansion type, having cylinders 27in., 43in. and 72in. in diameter respectively, with a piston stroke of 45in. Steam is supplied by two large single-ended boilers, worked on the Howden forced draught system, the steam pressure being 170 lb. per square inch. The air fan is in the engine-room, and is driven by a separate vertical engine. Mechan's triple automatic engine-room telegraph is fitted. The trial of the ship and her machinery was witnessed by Mr. J. C. Stewart, the superintending engineer for Messrs. Burrell and Sons.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

⁂ When patents have been "communicated" the name and address of the communicating party are printed in italics.

*9th August*, 1894.

15,177. Rails for Street Tramways, F. H. Gill, London.
15,178. Composition for Covering Boilers, G. W. Stones, Halifax.
15,179. Ships' Sidelight Scuttles, G. N. Arnison, jun., Sunderland.
15,180. Boots, W. Norman, Taunton.
15,181. Gully Shoot, J. J. Green and W. Oates, Halifax.
15,182. Compressing Fire-lighters, E. Pollard, Bradford.
15,183. Cutting Grooves in Fire-lighter Blocks, E. Pollard, Bradford.
15,184. Gauze Weaving, W. Strang, Glasgow.
15,185. Advertising Machines, G. Simpson, Glasgow.
15,186. Steam Motors, W. M. Walters, Liverpool.
15,187. Brush-boxes, H. E. Turner, Dorking.
15,188. Automatic Circulation of Water in Steam Boilers, C. L. E. Melsom and A. S. Morrison, London.
15,189. Slide Carriers for Optical Lanterns, W. Hunt, Glasgow.
15,190. Grinding Astigmatic Lenses, G. Prescott, Dublin.
15,191. Fire-escape, T. Gibbs, Hawley, near Dartford.
15,192. Light Railways, R. C. Sayer, Bristol.
15,193. Card Clothing, W. H. D. Uhlhorn, Manchester.
15,194. Tires, F. W. Brown, York.
15,195. Valves, G. Grossmann, Manchester.
15,196. Wire and Pale Fences, A. A. Wade, Leeds.
15,197. Machine for Cleaning Tin-plate, G. J. Record, London.
15,198. Means for Forging Nails, J. Luschowski, Liverpool.
15,199. Bottle Stopper, F. A. Maquet, Liverpool.
15,200. Waste Products of Gas Engines, G. and G. W. Bell, Liverpool.
15,201. Travis Motion of Spinning Mules, T. Ainsworth, Preston.
15,202. Cleaning Fur, W. Warburton and H. H., A., and A. Turner, Manchester.
15,203. Stuffing, &c., for Upholstery, J. Chadwick, London.
15,204. Ventilation of Hats and Caps, B. H. Bonner, London.
15,205. Colouring Matters, T. R. Shillitto.—(*J. R. Geigy and Co., Switzerland*)
15,206. Evaporating and Distilling Apparatus, W. Hood, London.
15,207. Paper and Fibrous Envelopes, W. Hood, London.
15,208. Flushing Cistern, D. G. Cameron, London.
15,209. Attaching Pneumatic Tires, J. Goodman, London.
15,210. Mine Ventilating Machinery, W. D. Simmons, London.
15,211. Receptacle for Infusing Tea, W. Lawes, London.
15,212. Power Hammers, T. Jameson.—(*R. M. Reay, United States.*)
15,213. Machines for Winding Yarns, H. Deutsch, London.
15,214. Hydraulic Motor for Vehicles, E. H. Toulmin, London.
15,215. Appliances for Swimming, G. Woollven, London.
15,216. Apparatus for Moistening Air, E. Mertz, London.
15,217. Photographic Gelatine Films, A. J. E. Hill and A. A. Barratt, London.
15,218. Soap-holding Device, A. J. Boult.—(*E. Hoffmann, Germany.*)
15,219. Preventing Influences between Electrical Lines, E. Müller, Liverpool.
15,220. Railway Carriage Window Sashes, M. E. Elder, Liverpool.
15,221. Stamping Plates, &c., W. H. Bleckly and the Pearson and Knowles Coal and Iron Company, Ld., Liverpool.
15,222. Disinfecting Dwelling-houses, &c., M. Wilson, London.
15,223. Golf Clubs, W. Hillman, London.
15,224. A Hood to Enable the Wearer to Breathe in Places Filled with Smoke, F. Wanz, London.
15,225. Converting Cast Iron into Malleable Iron, S. Hufty and J. K. Caldwell, London.
15,226. Indicating the Temperatures of Ovens, G. G. Brodie and J. D. Prior, London.
15,227. Manufacture of Water Cisterns, R. B. Evered, London.
15,228. Manufacture of Soaps, J. O. Klimsch, London.
15,229. Bottle Stoppers, H. H. Lake.—(*C. N. Brisco, United States.*)
15,230. Match Stand for Tables, A. H. Higginbottom, London.
15,231. Vulcanising and Drying Wood, C. Howard, London.
15,232. Panoramas, H. H. Lake.—(*E. Giordani, Italy.*)
15,233. Covering or Awning for Tramcars, &c, F. Ferguson, London.
15,234. Flower Holder, S. I. Gear, London.
15,235. Ferrules for Umbrellas, P. J. Cockrom, London.
15,236. Spanners, E. C. Cumming, London.
15,237. Handles of Umbrellas, &c., A. M. Jones, London.
15,238. Collar Studs, T. Ferrand, London.
15,239. Ink-bottles, B. Lees, London.
15,240. Foot Coverings, E. Lawrence, London.
15,241. Window Sashes, E. Andrews, London.

*10th August*, 1894.

15,242. Automatic Delivery Machines, W. Northorpe, London.
15,243. Steam Engines, J. Holloway, West Cowes.
15,244. Pneumatic Pads for Horse Collars, C. Esson, Liverpool.
15,245. Lubricating Spindles, R. Wood.—(*A. Coulter, Russia.*)
15,246. Communicating Rotary Motion, J. R. Alderdice, Belfast.
15,247. Starting and Stopping Tramcars, G. Gilchrist, Glasgow.
15,248. Registering Cab Distances, G. Baty, Stockport, near Manchester.
15,249. Utilisation of Waste Heat, C. J. Bagley, L. Roberts, and the Moor Steel and Iron Company, Stockton-on-Tees.
15,250. Baby Carriages, W. H. Dunkley, Birmingham.
15,251. Manufacture of White Lead, W. B. Priest, London.
15,252. Applying Brakes to Cycles, G. B. Main, Glasgow.
15,253. Corks, E. J. Frewen, Dublin.
15,254. Socks, L. Ousey, London.
15,255. Water Motor, R. Bray, Huddersfield.
15,256. Bath Glove, J. Wyatt, London.
15,257. Woven Driving Belts, J. C. Fisher, Manchester.
15,258. Manufacture of Lamp Shades, H. O'Reilly, London.
15,259. Carding Attachment, H. Thornton, Rochdale.
15,260. Cutting the Teeth of Saws, A. Rösle, Liverpool.
15,261. Nails, C. March, Glasgow.
15,262. Facing Inside Cylinder Valves, A. L. Daviess, Sheffield.
15,263. Caps and Guards, &c., for Cutlery, E. Price, Sheffield.
15,264. Wire-weaving Machinery, A. E. Wale, Birmingham.
15,265. Purification of Sewage Matters, S. Brown, London.
15,266. Manufacture of White Lead, E. van den Hoff, London.
15,267. Cord-holders for Window Blinds, F. W. Hitchin, Birmingham.
15,268. Protector for Pockets, &c., A. J. Nathan, London.
15,269. Manufacture of Tooth Paste, S. Levy, London.
15,270. Preventing the Twisting of Threads, G. M. Schreiber, London.
15,271. Improved Toy, A. E. Adshead, Manchester.
15,272. Oil or Hydrocarbon Engines, J. E. Weyman, Guildford.
15,273. Making Machine Bearings, J. D. Noble, Bristol.
15,274. Hand-driven Mechanism, S. J. Pocock, London.
15,275. Penholders, H. P. Clemetson, London.
15,276. Diaphragms for Electrolytic Purposes, M. Kiliani, Walter Rathenau, C. Suter, and Elektrochemische Werke Gesellschaft mit Beschränkter Haftung, London.
15,277. Tobacco and Cigarette Pouch, H. Manning, London.
15,278. Lock-stitch Sewing Machine, H. Manning, London.
15,279. A Combination Match-box, H. Manning, London.
15,280. Duplex Shirt-note Cuff, H. Manning, London.
15,281. Apparatus for Testing Wool, S. Jackson, London.
15,282. Ploughing by Electricity, F. Brutschke and H. Schimpff, London.
15,283. Improved Food Products, J. Campbell, London.
15,284. Advertising Bottles, &c., E. Gauche and J. L. Perréal, London.
15,285. Railway Carriage Couplings, B. C. M. P. de Lisle and G. P. Main, London.
15,286. Printer's Furniture, H. H. Lake.—(*A. Villa, Italy.*)
15,287. Washing Machines, H. W. Kolb, London.
15,288. An Improved Blind Roller, M. E. Reilly, London.
15,289. Wire Fences, P. R. J. Willis.—(*I. C. Allen, United States.*)
15,290. Washing Coal-tar, &c., S. B. Boulton, T. B. Haywood, H. E. Boulton, and H. Fergusson, London.
15,291. Apparatus for Paring Vegetables, C. Wolf, London.
15,292. Sinking Bore-holes in Quicksand, F. Honigmann, London.
15,293. Coal-screening Apparatus, D. Davy and Davy Bros., Ld., London.
15,294. Fuel Economisers, &c., J. G. Calvert, London.
15,295. Rings for Carrying Curtains, W. Woolf, London.
15,296. Tubulous Boiler with Superheater, W. Schmidt, London.
15,297. A New or Improved Settee, A. van Hoorn, London.
15,298. Sausage-filling Machine, W. von der Nahmer, London.
15,299. Supports for the Purposes of Observation, A. E. Wilson, London.
15,300. Rocking Chairs, A. Courquin, London.
15,301. Device for Use in Bath Chairs, C. H. Davey, London.
15,302. Water-closets, O. Elphick, London.
15,303. Manufacture of Biscuits, A. Smith, London.
15,304. Metallic Packing for Piston-rods, C. F. Churchill, London.
15,305. Yellow Coloured Silk, J. Y. Johnson.—(*The Badische Anilin and Soda Fabrik, Germany.*)
15,306. Fire-dogs, J. Fletcher, Birmingham.

*11th August*, 1894.

15,307. Manufacture of Gunpowder, L. G. Searson, London.
15,308. Stamping Piece-goods, J. F. Bramwell, Manchester.
15,309. Horseshoes, J. F. Bennett, W. Smith, and J. Wing, Sheffield.
15,310. Signalling upon Railways, J. Cocks, Manchester.
15,311. Gauges of Paper-cutting Machines, T. Smith, Manchester.
15,312. Gas Engines, J. F. Bennett and F. H. Stacey, Sheffield.
15,313. Cigar and Cigarette, &c., Cases, A. Ryan, London.
15,314. Fasteners for Millinery, E. P. Scruby, London.
15,315. Fasteners for Wearing Apparel, E. P. Scruby, London.
15,316. Gas Engines, J. F. Bennett and F. H. Stacey, Sheffield.
15,317. Manufacture of Lead Pigments, W. B. Priest, London.
15,318. Cork Drawers, N. S. McMillan and J. C. Stevenson, Liverpool.
15,319. Weaving Fabrics, G. H. Sargent and R. H. Coupe, Bradford.
15,320. Barometers, D. Logan, London.
15,321. Telephone Cords, G. Schrimpff and R. Riffelmacher, Manchester.
15,322. Can-making Machines, A. Johnson and H. C. Black, Glasgow.
15,323. Purifying Petroleum, J. Schrader, Liverpool.
15,324. Socks for Boots and Shoes, J. Gamble and H. Garland, Liverpool.
15,325. Surfacing Plugs and Cocks, J. Deam, Liverpool.
15,326. Brakes for Carriages, &c, H. Hollick, Coventry.
15,327. Varnishing Metal, J. Perl and P. Hermann, Berlin.
15,328. Studs, J. Brown, jun., and N. T. Thomson, Glasgow.
15,329. Preventing Mail Carts Running Away, C. Ellsworth, Glasgow.
15,330. Sash Frames of Windows, &c., W. Nicol, Glasgow.
15,331. Check-valves, W. Hinchliffe, Wakefield.
15,332. Mitre-cutting, &c., Block, W. O. Bailey, London.
15,333. Fluid Pressure Engines and Motors, J. Holt, London.
15,334. Freezing Mixture, H. Mansfield, London.
15,335. Steel Wheel for Cycle Purposes, A. F. Sage, London.
15,336. Compound Steam Engines, T. G. Clayton, London.
15,337. Liquid Cooler, J. G. Davies, London.
15,338. Candle Extinguisher, J. B. Goodwin, London.
15,339. Obtainment of Precious Metals, J. Mactear, London.
15,340. Horseshoes, C. Coplantz, London.
15,341. Cycle Tires, M. Boudard and H. A. Shelton, London.
15,342. Coupling Hold-backs to Carriage Shafts, G. C. Dymond.—(*S. F. Robbins, United States.*)
15,343. Tires for Cycles, &c., H. Claughton, Liverpool.
15,344. Improved Surgical Syringe, G. P. McGrath, Manchester.
15,345. Wheels for Carriages, &c., A. W. Thompson, Liverpool.
15,346. Cutting the Teeth of Bevel Wheels, G. C. Dymond.—(*P. Langen, Germany.*)
15,347. Rotary Brushes, F. Miotto and A. H. Simpson, London.
15,348. Chemical Compounds, H. E. Newton.—(*The Farbenfabriken vormals Friedrich Bayer and Co., Germany.*)

15,349. Boots and Shoes, C. Eisenberg and H. Humelet, London.

15,350. Couplings for Vehicles, G. Mellen and J. E. Sprague, London.

15,351 Evaporative & Surface Condensers, E. Theisen, London.

15 352. Pavements for Streets, W. M. Hodges, London.

15,353. Electric Motors, W. Routledge, London.

15,354. Apparatus for Cooling Purposes, A. J. Boult.—(*H. Dessolier, Algeria.*)

15,355. Refuse Destructor, W. Chambers, London.

15,356. Closing Electric Switches, D. T. Bostel, London.

15,357. Raising Water for Draining Purposes, J. W. Titt, London.

15,358. Wrenches, A. G. Brookes.—(*E. O. Ely, United States*)

15,359 Producing Flood-tight Joints, H. C. Platts and T. Lowther, London.

15,360 Arc Lamps, J. W. Rogers. London.

15,361. Antiseptic Agents, J. Y. Johnson.—(*Dr. F. von Heyden, Germany*)

13*th August*, 1894.

15,362. Frames of Umbrellas, &c., J. M. Cracknell, Ipswich.

15,363. Withdrawing Props in Mines, W. Sylvester, Longport.

15,364. Utilisation of Waste Steam, J. Wild, Manchester.

15,365 Dyeing Fibres, W. B. Hart and C. McKerrow, Manchester.

15,366. Concentrating Sulphuric Acid, I. Levinstein, Manchester.

15,367. Stoves, J. Gratton, W. Watson, and J. Taylor, Nottingham.

15 368. Brick Kilns, T., A., W. and H A. Martin Bristol.

15,369. Down-draught Preventers, J. Shaw, Willington-on-Tyne.

15,370. Bucket Jaws, J. Ellis, Bangor.

15,371. Paper and other Fasteners, G. Tucker, Birmingham.

15 372. Lamp Clips, F. J. Miller and C. A. Miller, Birmingham

15,373. Fixing Spiral Springs, D. Cremmen, London.

15,374. Saw-sharpener, G. C. Dymond.—(*F. Schmaltz, Germany*)

15,375. Polishing Mops, C. Taylor and T. H. Pearce, Birmingham.

15,376. Shades of Electric Lamps, &c. J. Whitehead, Birmingham.

15,377. Rod or Roller Curtains, A. Marsden, Stockton-on-Tees.

15,378. Nosebag for Horses, &c., A. Zillwood, Southampton.

15,379. Pianoforte or Orchestra Stools, T. Gapes, London.

15,380. Ventilators, R. R. L. Rosoman, Southampton.

15 381. Bushed Stop-rod for Reed Looms, J. Cook, Hyde.

15,382. Adjustable Swell for Reed Looms, J. Cook, Hyde.

15,383. Balling Heads for Fibres, H. Priestman, Halifax.

15 384. Ladies' Under Garment, M. C. Macgillivray, Glasgow.

15,385. Cycles and Wheeled Vehicle, G. B. Main, Glasgow.

15,386. Stay and Corset Busk and Eyelet, J. Farrow, Wavertree.

15,387. Billiard Tables, R. W. Wyett, Victoria, Australia.

15,388. Funnels for Filtering Purposes, H. J. Hands, East India.

15 389. Water-closet Joints and Pipes, H. Johnston, Liverpool.

15,390. Coal Vases, G. H. Shackleton, Bilston.

15,391. Pneumatic Tires for Cycles, A. I. Rath, Birmingham.

15,392. Mandolin-autoharp, A. L. Gautier, London.

15,393. Soda Water, A. Wedlich and T. Chaloupka, London.

15,394. Transporting Perishable Goods, J. H. Bowley, London.

15,395. Cycle Garments, W. Edwards and A. Gamage, London.

15,396. Electric Tramways, J. Hopkinson, London.

15 397. Cuffs and Sleeves of Garments, W. Green, London.

15,398. Long-arm, S. L. Gorer, London.

15,399. Covers for Pneumatic Tires, C. F. Dusart, London.

15,400. Colour Printing Machines, H. Brissard, London.

15,401. Vehicles. A. Leblanc, London.

15,402. Pattern Machines, F. W. Golby.—(*R. Kuöschke, Russia.*)

15,403. Automatic Alarm Device, C. H. Krützfeldt, London.

15,404. Lubrication of Bearings, S. Straker, London.

15,405. Tubular Section Steam Boiler, T. Henderson, London.

15,406. Cigarettes, G. C. Dixon, London.

15,407. Horse Blanket and Cover, J. Hopewell, jun., London.

15,408. Horse Blanket and Covers, J. Hopewell, jun., London.

15,409. Holder or Fastener for Gowns, J. G. Clegg, London.

15,410. Printing Machines, E. T. Cleathero and E. W. H. Walker, London

15,411. Railway Brake, C. C. Clifford and J. Carter, London.

15,412. Mashers, G. H. Zane, A. M. Snyder, and C. T. Worrell, London.

15 413. Heating Liquids and Air, E. Fudickar, London

15,414. Telephonic Call Bells, F. G. Warrell, London.

15,415. Fixing Cranks to Shafts, K. F. Lagergren, London.

15,416. Cabinets for Collections, &c., F. Dippel, London.

15,417. Construction of Fire-places, W. H. Haslam, Manchester.

15,418. Liquid Measures, W. P. Meadows, London.

15,419. Miners' Picks, W. K. Birkinshaw, London.

15,420. Device for Supporting Umbrellas, O. Cohen, London.

15,421. Device for Supporting Umbrellas, O. Cohen, London.

15,422. Winding Engine and Apparatus, J. Rousse, London.

15,423. Brake for Warp Beams, R. Haddan.—(*A. Biedermann, Germany.*)

14*th August*, 1894.

15,424. Electro-motors, D. Cook, Richmond.

15,425. Picking Hops, D. Young.—(*The Mills Hop Picking Machine Company, United States.*)

15,426. Extension Cranks, T. F. Bourne, London.

15,427. Pole Propeller and Pipe Motors, G. Paterson, Co. Fermanagh.

15,428. Fire-grates for Boilers, J. E. Rogers, Birmingham.

15,429. Conducting Electricity, J. Lindley and G. E. Sutcliffe, Mirfield.

15,430. Feeding Paper from a Web, J., F., and J. Y. Foster, London.

15,431. Spiral Spring Spoke, J. Phethean, J. Brown, and T. Charnock, Bolton.

15,432. Deadlights of Ships' Sidelight Scuttles, G. N. Arnison, jun., Sunderland.

15,433. Dyeing Colours on Fabrics, H. Wylie and J. Morton, Glasgow.

15,434. Puzzles, G. F. Fitter and W. H. Egginton, Birmingham.

15,435. Packing Rings of Pistons, W. Bagshaw, Nottingham.

15,436. Checking Pickers in Looms for Weaving, F. Jowett and J. Normanton, Halifax.

15,437. Winding Window-blind Rollers, J. Cook, W. Swarbrick, and H. Bernard, Lancashire.

15,438. An Improved Spittoon, J. Waltho, Stockport.

15,439. Pneumatic Tires, G. C. Moore, Manchester.

15,440. Tunnels, A. S. Dandridge, Manchester.

15,441. Apparatus for Filtering Sea Water, J. Pfister, Manchester.

15,442. Sketching Easels, T. Pursey, Edinburgh.

15,443. A Bench Vice, I. Carruthers, Sussex.

15,444. Danger Railway Signal, C. F. Williams, Monmouth.

15,445 Hydraulic Riveting Machine, W. Fairweather.—(*The Babcock and Wilcox Company, United States.*)

15,446. Telescopic Dark Tent Stand, W. M. Lynslager, London.

15,447. Window Sash Fasteners, J. H. Foote, London.

15,448. Attachment to Doors to Contain Notices, J. Westaway, London.

15,449. Treatment of Cancer, &c., J. Westaway, London.

15,450. Fasteners for Gloves, O. P. and G. O. Elterich, London.

15,451. Sharpening Razors, J. W. C. Kleeberg, London.

15,452. Electric Arc Lamps, H. H. Lake.—(*R. Drysdale, United States*)

15,453. Measuring the Amount of Gases, B. C. Tilghmann, jun., London.

15,454. Boiler Furnaces, D. J. McKenzie and W. Martin, London.

15,455. Telegraphic Transmitters, F. F. Howe, London.

15,456. Shaving Head-rests, S. J. Sewell, London.

15,457. Pipe and Cigar Lighter, E. H. Wheeler, Surrey.

15,458. Golf Bags, W. G. Davidson, London.

15,459. Metal-mesh Bows, D. Robinson, London.

15,460. Fire-proof Floor, J. Sheppard and F. Dashwood, London.

15,461. Hook and Eye Fastenings, D. Davidson and A. C. Clapp, London.

15,462. Casting Metals, R. Keostermann.—(*J Kudliez, Austria*)

15,463. Measuring Alcoholic Liquids, A. Bassett, London.

15,464. Rollers for Printing Fabrics, G. A. Muntz, London.

15,465. Bench Cramps, J. Hampton and J. Hampton, London.

15,466. Concrete and Iron Girders, F. G. Edwards, London.

15,467. Steam Road Rollers, E. T. Wright, London.

15,468. Solution of Sweet Carbamides in Oils, A. Sommer, London.

15,469. Treatment of Coal Dust, A. McDougall, Liverpool.

15,470. Prevention of Explosions in Mines, A. McDougall, Liverpool.

15,471. Condensing Rays of Light, A. Sciascia, London

15,472. Garment Clasps, S. Schwarz, London.

15,473. Making Green Oxide, F. L. Slocum and C. Y. Wheeler, London.

15,474. Sash Fastener, T. Beevers, J. A. Nealon, and W. Brett, London.

15,475. Compound Steam Engines, W. Schmidt, London.

15,476. Colour-printing Apparatus, H. H. Lake.—(*L. Josz and G. Pechenino, Italy.*)

15,477. Manufacture of Lace Curtains, E. Cope, London.

15,478. Repair of Pneumatic Tires, G. E. Osmond, London.

15,479. Valves for Pneumatic Tires, G. E. Osmond, London.

15,480. Pressure-regulating Valves, F. M. Sandillon, London.

15,481. Railway Switches, &c., D. MacPherson, London.

15,482. Article of Furniture, G. W. Ashwell, London.

15,483. Damping Gumming Sheets, W. J. Reynolds, London.

15,484. Miners' Trucks, E. Edwards.—(*E. Heinel, Germany.*)

15,485. Heating Apparatus, E. Edwards.—(*C. Müller, Russia.*)

15,486. Manufacture of Coke, E. Edwards.—(*The Internationale Gesellschaft für Torfverwaltung, Germany.*)

15,487. Apparatus for Filtering Water, H. Kowalski, London.

15,488. Surveying Instruments, W. Hinton, London.

15,489. Device for Curling Hair, W. S. Cooper, London.

15,490. Steam Generators, R. W. Mewes, London.

15,491. Gas Stoves, W. L. Wise—(*A. Rothenbach, Switzerland.*)

15,492 Treatment of Clothes, S. O. Cowper-Coles and H. B. Ransom, London.

15,493. Manufacture of Butter, J. H. H. Duncan, London.

15,494. Coin-freed Mechanism, A. Sussmann and F. Zahn, London.

15,495. Curtain Hangers, A. J. Boult.—(*J. G. Beck, Germany.*)

15,496. Turning Over the Leaves of Music-books, J. L. Lister, London.

15,497. Sighting Cards, J. H. Hogg, London.

15,498. Apparatus for Ventilating, R. W. McGregor, London.

15,499. Candle Holder, V. D Lake, London.

15,500. Device for Carrying Umbrellas, J. J. Osborn, London.

15*th August*, 1894.

15,501. Water-closet for Ships, &c., R. B. West, Isle of Wight

15,502. Spindles, C. Butterworth, Manchester.

15,503. Thread Guides of Winding Machines, E. Morris, Halifax.

15,504. Cutters for Cutting Metal Rods, J. B. Howard.—(*R. Filecek and Stephan Schwal, Germany.*)

15,505. Producing Heat from Petroleum, A. and M. A. Hobbs, Monmouth.

15,506. Volt Meters, F. Brown, Birmingham.

15,507. Joint for Connecting Water Taps, J. Barker and T. Handley, Rochdale.

15,508. Restraining Runaway Horses, J. Gorman and A. Bolt, Bristol.

15,509. Rug-strap Handles, J. Bailey, Walsall.

15,510. Ropes for Core-making, J. Butler, Manchester.

15,511. Chromo-lithography, T. H. Sale and W. Stead, Manchester.

15,512. Machinery for Spinning, W. S. Bancroft, Halifax.

15,513. Castings in Cement, G. Booth and M. Bolton, Stockton-on-Tees.

15,514. Cycles, H. Lucas, London.

15,515. Stands for Displaying Caps, T. Griffiths, London.

15,516. Carriage Lamps, W. T. Webber, Birmingham.

15,517. Malt and Hop Barm, G. Bartlett and W. Pearsall, Birmingham.

15,518. Lathe for Potters' Use, J. R. Pratt and W. E. Piercy, Staffordshire.

15,519. Securing the Handles into Jugs, T. Weir, Dublin.

15,520. Slabs for the Beds of Billiard Tables, J. Goodfellow, Glasgow.

15,521. Machines for Blowing Textile Material, J. A. Hart, Blackburn.

15,522. Manufacture of Fibre for Fabrics, A. Millar, Glasgow.

15,523. Saddle Framing, P. L. Renouf, Birmingham.

15,524. Steering Cycles, J. and H. J. Brookes, and P. L. Renouf, Birmingham.

15,525. Cure for Influenza, J. Wallace, Dublin.

15,526. Furnaces for Refuse, S. Willoughby, London.

15,527. Automatically Re-corking Casks, H. W. Rice, Nottingham.

15,528. Syringes, J. Macqueen, London.

15,529. Cutting Bobbins, J. H. Bale and W. H. Urch, London.

15,530. Stand for Paper-hangings, T. R. Shillito.—(*C. M. Patterson and H. B. Patterson, United States.*)

15,531. Indicating Device for Doors, H. B. Diamond, London.

15,532. Weldless Steel Chains, G. Stephenson, Glasgow.

15,533. Adaptation of Telephonic Sounds, T. J. Howell and F. Lake, London.

15,534. Vessels Containing Liquids, C. S. Snell, Cornwall.

15,535. Distance Indicators, A. J. Boult.—(*C. F. Briault, France.*)

15,536. Edge Setting Machines, A. Pochin, London.

15,537. Corkscrews, J. A Kruseman, Liverpool.

15,538. Velocipede Wheels, M. Boudard and H A. Shelton, London.

15,539. Machines for Cropping Cloth, J. and W. Burns, London.

15,540. Spray Producer or Fountain, C. R. Shilling, London.

15,541. Ruling Device, C. H. Davy, London.

15,542. Pipe Joints, F. R. Adair, London.

15,543. Steps or Ladders, W. R. Yates, London.

15,544. Automatic Safety Holder for Dresses, K. Wanaus, London.

15,545. Non-explosive Reservoir for Lamps, A. J. and A. A. Stonely, London.

15,546. Saddle Bars, J. A. Torrens, London.

15,547. Stays for Steam Boilers, R. T. Preston, London.

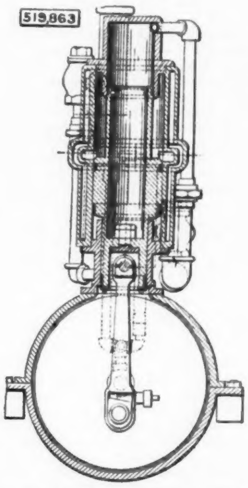
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**519,863.** Gas Engine, *D. C. Luce, Brockton, Mass.—Filed April* 14*th*, 1893.

*Claim.*—(1) A gas engine, comprising in its construction a cylinder having a central combustion chamber provided with an inlet port at each end and a centrally-located exhaust port, and charging chambers at each end of the combustion chamber and of less diameter than the latter, and each having a port, a piston having a central portion which fits the combustion chamber and receives the impact of the explosions, and extensions which fit the charging chambers, check-valved passages connecting the ports of the charging chambers with a fluid supply, and check-valved passages connecting said first-named passages respectively with the ports of the combustion chamber. (2) A gas engine, comprising in its construction a cylinder having a central combustion chamber provided with an inlet port at each end and a centrally-located exhaust port, and charging chambers at each end of the combustion chamber and of less diameter than the latter, and each having a port, a piston having a central portion which fits the combustion chamber and receives the impact of the explosions, and extensions which fit the charging chambers, check-valved passages connecting the ports of the charging chambers with a fluid supply, check-valved passages connecting said first-named passages respectively with the ports of the combustion chamber, and hot tubes communicating by restricted passages with the second check-valved passages.

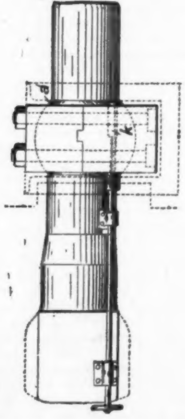
519,863



**519,965.** Gun Mounting, *J. L. Norris, Washington, D.C.—Filed July* 27*th*, 1893.

*Claim.*—(1) In a field gun or other ordnance, the combination of a spherical portion *a'* formed on the gun in lieu of trunnions, and a clip of corresponding spherical form internally, and bearing upon and supporting said spherical portion of the gun and adapted to grip and lock the gun firmly in position when required, the said spherical portion and the clip constituting a form of ball and socket or modified universal joint, substantially as shown and for the purpose specified. (2) In a field gun or other ordnance the combination with a spherical portion formed on the gun in lieu of trunnions and a corresponding spherical clip, of wedge pieces *k k* and means for operating them to grip and lock the gun, substantially as described.

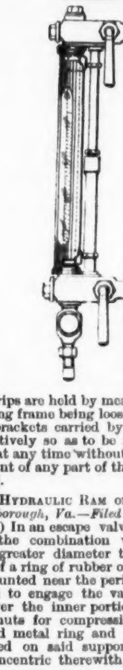
519,965



**519,957.** Guard for Water Gauges, *J. A. Hopkinson and J. Hopkinson, Huddersfield, England.—Filed December* 15*th*, 1893.

*Claim.*—(1) For a glass water gauge, the combination of the upper and lower brackets mounted respectively on the steam and water arms of the gauge, a frame loosely resting in said brackets, and glass loosely resting in said frame, substantially as described. (2) For a glass water gauge, the combination of upper and lower brackets mounted respectively on the steam and water arms of the gauge, a frame made in one piece loosely resting in said brackets, and flat glass strips loosely resting in said frame, substantially as described. (3) For a glass water gauge, a shield or guard comprising a frame in which readily removable flat glass strips are held by means of turnbuttons, said glass carrying frame being loosely supported in upper and lower brackets carried by the steam and water arms respectively so as to be readily attachable and detachable at any time without requiring the removal or adjustment of any part of the gauge, substantially as described.

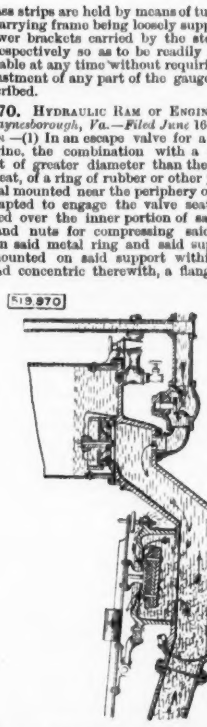
519,957



**519,970.** Hydraulic Ram or Engine, *W. A. Rife, Waynesborough, Va.—Filed June* 16*th*, 1893.

*Claim*—(1) In an escape valve for a hydraulic ram or engine, the combination with a circular ridgid support of greater diameter than the interior of the valve seat, of a ring of rubber or other yielding elastic material mounted near the periphery of said support, and adapted to engage the valve seat, a metal ring mounted over the inner portion of said rubber ring, bolts and nuts for compressing said rubber ring between said metal ring and said support, a rubber disc mounted on said support within said rubber ring and concentric therewith, a flanged valve stem mounted over said rubber disc, and bolts and nuts, adjustably connecting said support, said rubber disc, and said flange together, substantially as and for the purposes described. (2) In a hydraulic ram or engine, a circular delivery valve provided with a metallic body perforated with curved gridiron ports, a flap of leather or similar material mounted over said ports, a perforated rubber disc beneath said valve body, a perforated ring provided with curved ribs secured beneath said perforated rubber disc, and means for securing the said valve body, leather flap, rubber disc, and perforated ring together, substantially as described.

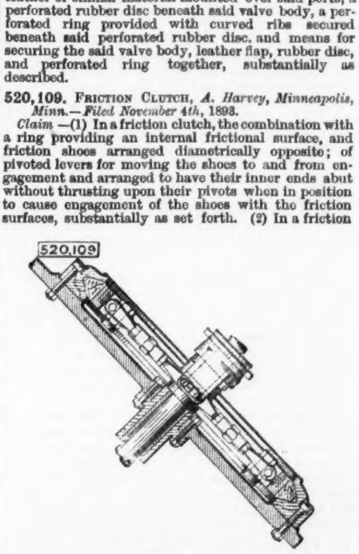
519,970



**520,109.** Friction Clutch, *A. Harvey, Minneapolis, Minn.—Filed November* 4*th*, 1893.

*Claim*—(1) In a friction clutch, the combination with a ring providing an internal frictional surface, and friction shoes arranged diametrically opposite; of pivoted levers for moving the shoes to and from engagement and arranged to have their inner ends abut without thrusting upon their pivots when in position to cause engagement of the shoes with the friction surfaces, substantially as set forth. (2) In a friction clutch, the combination with opposite radially movable shoes and a circular frictional surface; of radially arranged levers having loose pivotal connections with a shifting device, whereby their ends may be thrust to contact, substantially as and for the purpose set forth. (3) In a friction clutch, the combination with a ring having an internal annular groove; of friction shoes; levers for operating them, the levers having their inner ends arranged to abut; a shifter having arms to which the inner ends of the levers are pivoted in slots permitting longitudinal movement of the levers; and arms extending from a hub on the shaft and attached to the shoe carriers for causing them to rotate with the ring, substantially as set forth.

520,109



## THE IRON AND STEEL INSTITUTE.

ON Tuesday the members of the Institution left Brussels at 2.0 p.m. by special train for the Antwerp Exhibition. About half way, what might have been a very serious accident occurred. The train slowed down for signals. It appears that the driver had not sufficient experience in the use of the Westinghouse brake on very long trains. Applying it too quickly, the back of the train pressed on the front, compressing the buffer springs. The moment he released the brake on the engine the buffer springs acted; a very violent jerk took place. The draw bar between the leading brake van and the first passenger coach gave way. The side chains broke as a matter of course. The brake pipes fell apart, and the automatic action instantly jammed the brakes hard down, and the train stopped suddenly. One gentleman received a bad black eye, another had two teeth loosened, and a third was flung full length on the carriage floor. The engine went away with the damaged carriage, placed it in a siding, and came back for the train, which reached Antwerp without further accident. There was a reception held beneath the dome, Antwerp officially welcoming the visitors. In the evening there was a special illumination of the grounds, and the visitors returned to Brussels by special train at 10.30.

At the commencement of the proceedings on Wednesday, the second day of the meeting, the President, whose term of office expires in May, 1895, announced in accordance with the usual practice that the Council had selected Mr. David Dale as his successor, a nomination which was viewed with considerable satisfaction by the members present. Mr. Dale's connection with the Institute has been so long and intimate—he having acted as honorary treasurer since its foundation—that the choice of the Council seems to be particularly appropriate.

The first paper read—"Notes on Electrical Power"—was by Mr. Selby-Bigge. We reproduce it in full on another page.

It dealt with a subject of much importance and attracting a great deal of interest just now. The discussion which followed was of very little importance. There was no one present, indeed, who possessed sufficient experience or knowledge of the subject to add much information to that supplied by Mr. Selby-Bigge—and even if there had been, time was not available for long speeches.

Mr. Wicksteed said that, inasmuch as the motor performed best, as he understood, when running at 800 revolutions, it was probable that much loss of efficiency might occur when the speed was lowered. He wished to know if this was the case, because the speed of the motor must vary a good deal. A crane appeared to supply an admirable means of testing for efficiency, because the weights lifted being known and the power expended being known, all the elements of information were supplied in actual foot-pounds per minute expended by the engine, and represented by the weight lifted by the crane. He wished furthermore to know how, for foundry work, the speed could be controlled. In lifting a pattern, for example, out of a mould, the lifting had to be done very slowly and cautiously.

Sir I. L. Bell said it was a regrettable fact that the electrical engineer was spoiling the landscape by using up the waterfalls, and to him, at least, it was small compensation for the loss of a lovely cascade, to be told it was lighting a little town, which he had never before heard of, twenty miles off. But his principal object in rising was not to find fault, but to say that his sons were about to apply electricity to drive the large quantity of machinery in their ammonia soda works, so satisfied were they with what they had seen in Belgium.

Mr. Louis said that it might interest the members to know that a cascade on the north side of Hellvelyn had recently been utilised to provide power for working the Greenside lead mine, a considerable distance away, with much success. Electricity was employed at the mine, both in pumping and boring. Only a small dam had been required to impound the water.

Mr. Webb pointed out briefly that electricity was admirably adapted for driving textile machinery, and was gradually finding its way into spinning mills. He was followed by Mr. Adamson, who said that it was hard to realise the loss incurred in shop and overhead travelling cranes driven in the ordinary way. In one case which he mentioned, the overhead traveller in a shop 250ft. long was driven by a fly-rope running at a speed of 4500ft. a minute. Between 11 and 12-horse power were required merely to keep the rope running. He was confident that not 33 per cent. of the indicated power of the engine reached the load to be lifted. If electricity was used, he felt confident the efficiency would be at least 50 per cent. Leaving the question of cranes, he pointed out that one of the great advantages of electric driving was that tools could be put down just where they were wanted. This was a matter of very great convenience in boiler shops. It often happened that it was desirable to rearrange the tools in a shop. Nothing was easier with electric driving, nothing more troublesome when lay shafts and belts were used. He felt certain that in the future all textile machinery would be driven direct by motors from one great central engine in each mill, and that nothing but electric cranes would in a short time be employed.

Mr. Selby-Bigge, in reply, said that it would probably not pay to employ special slow motors referred to by Mr. Wicksteed, as they were heavy and expensive to make. But they were not wanted; because in all overhead travellers, whether driven by hand or steam or electricity, there were several motions obtained by gearing and clutches. But when electricity was employed the clutch and gearing were got rid of, a separate motor being employed for each special motion. A most important application, he considered, of electricity was to driving the live rollers of rolling mills. In one case where 50 to 60-horse power of steam was used in this way, it was found possible to do the whole work with six motors of 8½-horse power each, which took up the work one after the other as the bar passed over the rollers. As to textiles, it was most admirably adapted to the purpose, and was already largely employed in a big mill in Ghent. One of the great advantages of electric driving was that the ammeter and volt meter reported at once to the engineer what was going on; he could see at a glance what power was being expended. Leaks and losses of all kinds automatically reported themselves in the office; with steam nothing of the kind was possible. The losses going on daily were enormous and unknown. In one instance he found that 76 per cent. of the whole power of the engine was wasted in driving line shafts and belts alone. And although this was perhaps exceptional, still enormous loss of power did no doubt almost always go on. This could, as he said, be avoided by the use of electricity. A vote of thanks was passed to Mr. Selby-Bigge for his paper.

The next paper was by Mr. J. A. Lencauchez,

### "ON THE MANUFACTURE OF STEEL IN THE OPEN HEARTH."

This paper was given at considerable disadvantage, having been hurriedly prepared and circulated in the meeting without illustrations, owing to the delay of the author in supplying the manuscript. Such delays are not unknown in societies whose members, all living in one country, are more amenable to secretarial control, and therefore, can scarcely be avoided in the Iron and Steel Institute, where the members are pretty much at large all over the world. The author, after noticing some experiments made at Styring-Wendel in a rotary furnace, with the addition of an artificial blast to promote decarbonisation by direct oxidation, described a furnace used in the production of dead soft steel at the Escaut and Meuse Works at Anzin, in the north of France. This is an open hearth furnace with plunging gas burners, and a slightly domed roof of the ordinary pattern which can be supplied with air under pressure from tuyere tubes in the roof near the spring of the arch, as well as at the top of the melted metal in the bath. The roof is made double, with an intermediate space through which the air for the top blast is admitted. The bed of the furnace as well as the noses of the gas and air ports are built in bricks made of Eubœa magnesite. The action of the blast is two-fold; the upper tuyeres promote the combustion under the roof of carbonic oxide evolved in the bath instead of allowing it to burn in the regenerators, where it is comparatively inefficient, while the lower ones at the hearth level supply air for the direct oxidation of the carburised metal in a similar manner to the action of the blast in the cupellation of argentiferous lead. Another modification in construction was the use of thin, closely-set, parallel walls of brickwork for the heat intercepting mass in the regenerators, instead of the ordinary chequer work, in order to diminish the chance of lodgment of dust by avoiding horizontal surfaces.

As regards the results obtained at the works of Escaut and Meuse at Anzin, where the method is mainly the pig and scrap process, the proportion of pig iron has been increased relatively to that of the scrap iron, of which the chief component is old rails. The charges are made up of two-fifths of hematite iron, and three-fifths of old iron, scrap, &c., for the production of extra soft steel, with an elongation of 25 to 30 per cent. Since the application of blowing the results have always been very satisfactory. In twenty-five effective working days the minimum outturn per month is 1000 tons of sound ingots. The average useful production per day of real work is from 40 to 42 tons, with a consumption of 275 kilogrammes—605 lb.—of coal in the producers per ton of ingots, including lighting up. The fuel used consists of about 58 per cent. of run of the mine from Flènu, and 42 per cent. of small coal of 4 centimetres, from Bruay. The number of heats is regularly four per twenty-four hours throughout the month. The silica roof lasts a minimum of 200 heats. Before the introduction of the blow-pipe arrangement in the roof, the furnace only produced 30 to 32 tons of steel per twenty-four hours, but, thanks to the dust catchers arranged as described above, too frequent stoppages have been obviated, and the monthly production previously mentioned has been attained. Prior to blowing, with the furnace working under the same conditions as to quality of steel and fuel, the coal used in the producers amounted to 340 kilogrammes—748lb.—per ton of steel made.

Only one Root's blower is used, and the following particulars show the progress of the operation, with an average charge of 10,800 kilogrammes — 10·8 tons:—Natural draught, twenty minutes; blowing during charging, one hour; blowing before complete fusion two hours, twenty minutes; natural draught, one hour forty-five minutes. The total duration of the operations is thus five hours twenty-five minutes. Whilst blowing, the gas is turned full on, and the pressure of the blast is 0·580 metre — 22·84in. The greatest pressure that the Root's blower is capable of producing is 0·750 to 0·800 metre—29·53in. to 31·50in. Under these conditions, the amount of air blown in per second for the six tuyeres is 0·397 cubic metre—14 cubic feet—and for the whole operation, it amounts to 4764 cubic metres—168,148 cubic feet—or about 30 per cent. of the total quantity of air.

The great economy of blowing-in air in the manufacture of steel in the open hearth is thus rendered clearly visible. It was intended to make some trials with the blast at higher pressures, and also with the ore process. Some suggestions bearing in this direction are as follow:—In the new plant, to make use of the blast from a Bessemer blowing engine, giving a pressure of 1·75 kilogrammes (3·85 lb.). This will enable the quantity of blast to be reduced to 10 or 15 per cent. of the total amount of air, and it is here that the use of the great development of the air regenerators will appear, for the hot air in excess will be forced down on to the bath by the tuyeres. Besides this, it will be possible to inject hot air through the tuyeres; but this complication does not appear to our minds to be necessary, unless the furnace is close to the hot-air stoves of a blast furnace.

The procedure with a furnace, or, better, with two furnaces, would be as follows: The metal is fused at a relatively low temperature in a slightly oxidising flame to obtain the desulphurisation by the manganese contained in the pig iron, or added in the form of ferro-manganese. The slag is mainly composed of sulphide of manganese and lime, and after rising to the surface is skimmed off. By slightly raising the tenperature of the bath and by blowing, nearly all the silicon and phosphorus is oxidised, and the bath is rabbled as formerly. Lime is added to neutralise the last traces of phosphoric acid, and the bath is again cleaned. Combined with the blowing, it will be possible to oxidise, by successive additions of hematite, magnetic oxide, or other ores, which should be as pure as possible and with calcareous gangues. It will be, however, advantageous to diminish the use of these oxides to a minimum, especially if they are difficult to obtain. The elimination of sulphur, phosphorus, and silicon is effected at temperatures lower than that at which decarburisation commences, or, in other words, at which carbonic oxide is generated. At these relatively low temperatures the basic walls do not suffer. The refining of the metal thus obtained can be finished in a second furnace, the first one forming a sort of a washing furnace. Decarburisation can be performed with a very small minimum of ore, or the ore may be entirely omitted, for the points that will have to be looked after are the shortening of the operation, as well as the most economical results. The smaller the quantity of ore, the less will be the amount of slag, the shorter will be the time required for mending the lining, and the lower will be the cost of making iron into steel. To sum up, the object of blowing air into the open hearth is not only to increase the outturn, but also to refine as much pig iron as possible by air. This ought to lead us to much less costly conditions, owing to the smaller quantity of slag, and its removal at a relatively low temperature. The use of the blast allows the temperature of the hearth to be very easily and rapidly varied, and it is applicable to existing furnaces.

Some amusement was caused by the President, after stating that the paper was essentially one to bring forth communications from the younger members of the Institute, calling upon Mr. James Riley to begin the discussion. Mr. Riley stated that he had used blast in the open hearth furnace, but the advantage was not sufficient to compensate for the complication introduced in working.

Mr. Snelus thought the great advantage of the open hearth over the Bessemer process was in the extra yield obtained when iron ore was used as the softening material, and this would be lost if direct oxidation by air were to be adopted. Mr. Bauerman pointed out some features in the design, recalling the top blast of the earlier gas fired furnaces, and which had in course of time been mostly given up in favour of natural draught.

Mr. Paul thought that the melting down might be accelerated by the use of blast, but that if hot air were used as suggested the roof would probably be melted down in twelve hours, and that, generally, intense local heating at any point in the furnace was to be deprecated. He had found the chequer work in basic furnaces to stand for six months without cleaning. As in the filling the regenerators, straight walls like those used by the author were advantageous for heating the gas, but for the air ordinary chequer work was best.

Sir Lowthian Bell thought that the top blast might be more useful in preserving the roof by keeping off the body of flame rather than promoting intensity of combustion.

The discussion on Mr. Lencauchez's paper, although not protracted, lasted till noon, so that only a very short time was available for the remaining papers on the list. One of these by Mr. R. de Soldenhoff, on the "Manufacture of Coke," which had been prepared with a view to full discussion, was taken as read, as on account of the lamented decease of the author since the paper was written, the proposed discussion was necessarily abandoned. Mr. W. C. Macmillan briefly explained the construction and method of working of two new forms of colour gauges for use in the determination of carbon in steel by the Eggertz process, one of them being based upon the comparison of tints reflected from white dye through a colouring of coloured liquids when observed in the field of a total reflecting eyepiece above; and the other on direct observation of the light transmitted through the columns from a reflector placed below. These instruments, although comparatively simple, contain several ingenious refinements in construction intended to do away with sources of error in appreciating tints of colour that accrue in the older methods of colour determination. The following table summarises the results obtained with the two forms of instrument, pattern A being that depending on the observation of reflected, and pattern B of transmitted light.

| Steel mark. | Carbon found by combustion. | Carbon found by colour gauge. | |
|---|---|---|---|
| | | Pattern A. | Pattern B. |
| A.... | 0·15 | 0·16 | 0·16 |
| B.... | 0·22 | 0·22 | 0·21 |
| C.... | 0·43 | 0·42 | 0·43 |
| D.... | 0·46 | 0·47 | 0·46 |
| E.... | 1·41 | — | 1·42 |

In these tables A, D, and E represent the British Association standard steels, Nos. 4, 3, and 1 respectively.

The last paper read before the final adjournment on Wednesday was by Mr. A.P. Wilson, on the

### "IRON ORES OF THE MEDITERRANEAN SEABOARD."

This was a short summary of the different iron ore deposits existing at different points in Spain, Italy, Algiers, and further East in the islands of Greece and the Levant, but dealing more particularly with those of the southern provinces of Spain which lie within reasonable distances of shipping ports, and which may therefore be likely to become of importance in the not very distant future, when the supply from Bilbao must diminish if it does not entirely cease. In the opinion of the writer, the iron ore producing provinces of the south of Spain, and especially those of the province of Almeria, will unquestionably play a large part in the immediate future as exporters of iron ore. The ores from this province are already fairly well known, and the output, which at present is steadily growing, will shortly increase with great rapidity. Several purchases of mines in the southern provinces of Spain have been made during the last two years, chiefly by Bilbao mine-owners, and as soon as these properties have been opened up, and transport to the coast has been provided for, a great and sudden increase in the quantity of iron ore exported from these provinces may be confidently predicted. There are ores of every class in the southern districts—brown hematites, low in iron, high in water both free and combined, and producing about 80 per cent. of smalls; hard and purple-hematites, carrying 55 per cent. of iron and 3 to 4 per cent. of manganese, 80 per cent. being lumps; and manganiferous ores containing over 50 per cent. of iron, and 12 per cent. of manganese. The principal iron ore producing provinces of the South of Spain are Murcia, Almeria, and Malaga, and the production for the past three years has been as follows;—

| | 1891. Tons. | 1892. Tons. | 1893. Tons. |
|---|---|---|---|
| Murcia | 350,000 | 388,000 | 300,000 |
| Almeria | 163,224 | 174,350 | 115,000 |
| Malaga | 99,589 | 70,700 | 55,000 |
| Totals | 612,813 | 633,050 | 470,000 |

The decrease in production for 1893 is accounted for to a great extent by the coal strike which took place in England in that year. Freights consequently increased, and during the latter part of the year it was almost impossible to obtain boats, so that work had to be suspended at many of the mines. It will be seen that the production of the whole of the south of Spain is at present only from one-sixth to one-eighth of that of Vizcaya alone; but year by year, as the produce of the latter declines, that of the former may be expected to increase, and the outputs of the North and South will gradually approach one another. The deposits, however, of the southern provinces are not in any way so extensive as that of Bilbao; it is probable that all the workable deposits at present known in the South do not contain more than one-half the quantity of ore that was once available in the Bilbao mines. On the other hand, however, the mines of the South have several advantages over those of the North. Labour is there considerably cheaper, the climate is much drier, and freights, taking the average of the whole year, are not in excess of those which are paid from the nearer port of Bilbao. A large proportion of the ore, too, is superior to the Bilbao ores, the southern Campanil being of better quality than the average Bilbao Campanil, in that it contains more iron and less silica, whilst the northern district cannot boast of such ores as the manganiferous ores of Herrerias in Almeria and of the Cartagena district in Murcia. The lowness of Mediterranean freights is accounted for by the fact that larger steamers can load at ports on the southern coast of Spain than at Bilbao, which is known to be a shallow-water port; moreover, the amount of despatch-money earned under charters of steamers from the south of Spain is very large, amounting to 2s. per ton or thereabouts. This dispatch is not earned from steamers which load at Bilbao. An estimate was made and an average taken of the freights paid from the south of Spain to the east coast of England, and it was found, after taking into consideration the profits under the charter party, that the freight from the south of Spain for that period was somewhat less than that paid from Bilbao. At the present moment the freight from Bilbao to Middlesbrough is between 5s. and 5s. 6d.; whilst from the south of Spain ports—such as Garrucha and Almeria — it is 8s. 3d., a difference at first sight therefore of 3s. per ton in favour of Bilbao; but when it is considered that steamers from the south of Spain pay 10d. per ton for loading and 10s. per hour despatch at both ends, which, as mentioned before, is worth 2s. per ton, and that they also pay a higher rate for discharging than the actual cost, it will be seen that the emoluments under charters from the south of Spain amount to more than 3s. per ton. As the tonnage of the world is increasing rather than decreasing in size, it is only fair to suppose that the difference in favour of the south of Spain will be further demonstrated as times goes on. The principal iron ore mining centres in the south of Spain are:—Cartagena, Calasparra, Morata, and the Sierra Enmedio, in the province of Murcia: Herrerias, Sierra de Bèdar, and Sierra Alhamilla, in the province of Almeria; and Marbella, Robledal, and Estepona, in the province of Malaga.

In no case do these southern deposits occur as true lodes or veins; they have invariably been produced as beds or deposits by a system of replacement. They occur for the most part upon schistose rocks, and are covered by limestone or dolomite. There can be no doubt that at one time the limestone rested on the schist rock, and that, in the course of ages, they were gradually dissolved by acid waters carrying iron, which metal replaced the dissolved limestone. As a general rule, there is in these southern deposits no clear division between the iron ore and the limestone, the former, as it were, growing into the latter. Hard, isolated masses of limestone occur also in the midst of the ore bodies. On the other hand, the division between the iron ore and the underlying schist is quite clear and well-defined. At the point of contact the schists are generally altered or decomposed to a soft white clay or kaolin, whilst lower down they are hard and of a blue colour. The deposits are all situated in the slopes of mountain ranges, and are in most cases very favourably placed for working by open-cast.

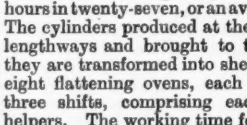
After the reading of Mr. Wilson's paper the formal business, including votes of thanks to the Reception Committees of Brussels, Charleroi, and Liége, the Communal Authorities of Brussels, whose co-operation did so much to ensure the success of the meeting, occupied only a few minutes, and the meeting adjourned at 12.30 p.m. on Wednesday. Having regard to the numerous counter-attractions presented to the members by one of the brightest and liveliest cities in Europe, their attendance was kept up with commendable regularity throughout.

On Wednesday afternoon the members were left to follow their own devices. Messrs. T. Cooke and Son had arranged a carriage drive in Brussels, all the principal places of interest being visited. This was well patronised. At 8.30 his Majesty the King of the Belgians, who is an Honorary Member of the Iron and Steel Institute, gave a reception and conversazione at the Palace, which was crowded. All the state rooms, save the great ball room, were thrown open; an admirable band supplied music. In one of the conservatories refreshments were provided on the most liberal scale. His Majesty, although in uniform and attended by several officers, did not assume state. He moved among his gratified guests and performed the duties of a host as a gentleman entertaining ladies and gentlemen. It is not remarkable that his Majesty and the Queen, who was not in Brussels, are excessively popular.

On Thursday, August 23rd, members left Brussels by two special trains from the Midi station at 8.20 and 8.40 a.m. The trains consisted each of about twenty first-class coaches, weighing each 17 tons, and drawn by very powerful engines. The arrangements were as follow:—The party was divided into groups, each provided with a distinguishing badge, of different colours, and bearing letters. "A," going by the first train, visited Pit No. 5 of the Bascoup Company. After inspecting the shaft, the screening and washing plant, &c., the members passed into the *Cité ouvrière* No. 1, thence on foot, by way of the park of the Château of Trazegniès—the property of the Bascoup Colliery—to the Trazegniès Railway Station, where train was taken to Charleroi. The Mariemont and Bascoup Collieries raise 1,200,000 tons of coal annually. "B," the second group, proceeding by the 8.40 train, visited the establishments of Baume and Marpent at Haine St. Pierre. "C," the third, travelling by the same train, visited the Mariemont Glassworks at Haine St. Pierre, about 1000 yards from the station of that name. 12.30 p.m., lunch at Charleroi. 2.30 p.m.: Four groups were formed, visiting — 1, The Marcinelle and Couillet Works at Couillet; 2, the "Glaceries de Charleroi" at Roux, near Courcelles; 3, the Marchienne Collieries at Marchienne, and the Sacre-Madame Colliery at Dampreny; and 4, to the Jonet Glassworks at Charleroi. 5.55 p.m.: Left Charleroi for Brussels.

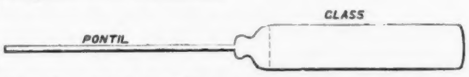
We shall confine ourselves for the present to the movements of group "C." On the arrival of the train at Mariemont, the party proceeded to the glassworks, the Verreries de Mariemont. These works are wholly devoted to the production of window glass of all kinds, under the management of M. Paul Noblet. We cannot do better in the first instance than reproduce here the contents of a card placed in the hands of each of the visitors.

"The sheet glass works of Mariemont were founded in 1828. These works are exclusively engaged with the manufacture of window glass: single or 16 oz. per foot, 21 oz. per foot, 24, 26, 28, 32, 36, and 42 oz. large sizes and ornamental glass. They occupy 600 workmen. Their means of production consist in two tank furnaces working without interruption. The two furnaces are of the vault form, and with independent burners in order to allow the partial repairing of each of the furnaces without stopping the fires. The gas generators are of the vertical column type, supplied with a heavy charge of coal and forced draught under a horizontal fire, allowing the exclusive use of small coal. The heating surface of the two furnaces represents respectively 100 square metres and 75 square metres, producing together an average monthly area of 1,500,000 square feet of blown glass. The two together contain 560 tons of melted glass. These furnaces employ 210 men, viz.: sixty blowers and sixty gatherers. The workmen are equally divided into three shifts, these working each eight hours, with one hour interval between each shift. Consequently, each furnaceman works eight hours in twenty-seven, or an average of 215 hours per month. The cylinders produced at the furnaces are cracked open lengthways and brought to the flattening ovens, where they are transformed into sheets. The works have also eight flattening ovens, each of them being worked by three shifts, comprising each one flattener and three helpers. The working time for the flatteners is the same as for the blowers. The flattening ovens are heated with coal-gas coming from the gas generators with natural draught—Siemens' system. The cylinders to be flattened are progressively heated in an arch oven and then flattened on a stone which is carried on a trolley, after which the sheets are conveyed towards an annealing furnace, where they are advancing gradually till their coming out of the apparatus. In each flattening oven there are two flattening stones carried on trollies with a siding. This arrangement enables the flattener to work without interruption. From the flattening ovens the sheets are sent to the cutting-rooms, where they are cut into panes, following the usual trade sizes, then classified according to their sizes and qualities into lots of 100ft., 200ft., 300ft., and then packed and shipped. The Belgian sheet glass works are exporting 95 per cent. of their production. Their principal outlets are England, the United States of America, after which come India, China, and Japan, the English Colonies, and the Mediterrenean."



The tank furnace has very largely superseded the old-fashioned pot furnace. It is in plan of the shape shown in the sketch. Internally it is some 30ft. long, and half as wide. The mixture of sand, alkali, and "frit," or broken glass, is charged from time to time through the door B. As it melts and glass is formed, the molten "metal" gradually finds its way to semicircular end in which are openings C C C, through which the glass is withdrawn by the workmen. The heat, which is extremely intense, is supplied by gas producers, modifications of Siemens' type, air being forced in by vertical steam jets, blowing down into trumpet-mouthed air pipes. The whole roof of the furnace is so carried in the buck staves that it can be raised or lowered a little, so that when worn it can be dropped slightly to preserve it the right height above the "metal." For the benefit of the visitors, M. Noblet had provided a wooden screen at some distance in front of the charging door, and in this was fitted a large pane of blue glass. Each of the visitors was handed a small pane of the same material, and with the aid of these two it was possible to see from end to end of the furnace, and the sight will not be readily forgotten. When the gas was turned off there was visible a vast grotto. In the front a mass of sand, bubbling and heaving and boiling. Further on a pool of partly molten sand, and near the end D a placid pool of molten glass reflecting the roof and sides, the whole quivering and shimmering in the intense heat. From time to time appeared the end of a rod, black by contrast, really bright red hot; or the end of one of the great glass cylinders, also black by contrast. Then the gas valve was opened, and over all floated lazily lovely violet clouds of flame. There was no noise, no violence, no turmoil. It was impossible to believe that here was a temperature which only the best firebricks from Dinas can withstand for any time. There were, we think, few among the visitors—all men well versed in furnaces and high heats—who could resist an exclamation of admiration as they looked at what we have vainly endeavoured to describe. It must not be forgotten that in the glass tank furnace the utmost care is used to obtain a perfectly clean heat, and the atmosphere was accordingly within the furnace almost entirely free from dust.

In making the glass, a boy takes a "pontil," a tube of iron about 8ft. long, and weighing 22 lb. He dips the end of this into the furnace and collects some glass on it, withdraws the ball and allows it to cool a little, and so goes on until the weight becomes greater than he can manage. Then the blower takes the pontil and collects more glass, until he has a ball twice the size of a man's head. This he rests in a hollowed block of wood, and, blowing through the pontil, begins to form a globe. Next, standing on a platform, he begins to swing the globe backwards and forwards like a pendulum, blowing the while, and so the globe becomes a cylinder. It is heated from time to time by thrusting it into the furnace for a moment, and so at last we have a cylinder of glass some 3ft. long and a foot in diameter, with a hemispherical end. On to this end a boy dabs a little bit of hot glass. This apparently causes a fine crack. The cylinder is thrust into the furnace for the last time. The end of the pontil is stopped by the workman's thumb. The air expands, there is a little explosion, and the end of the cylinder opens. Then we have a cylinder on the end of the pontil as in the sketch.

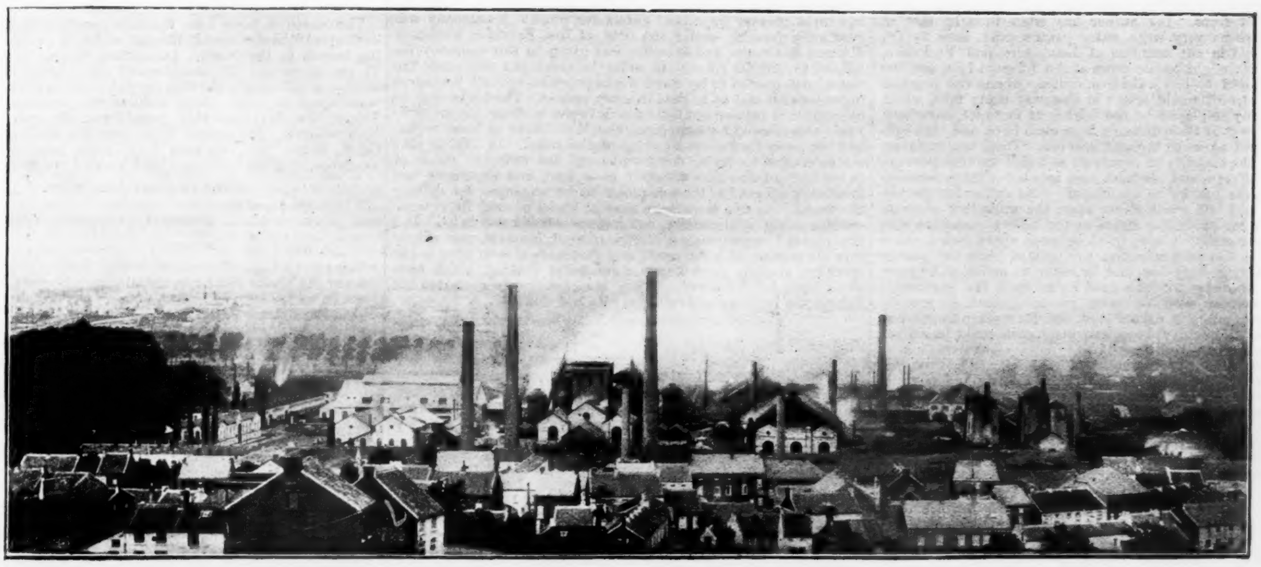


Then the cylinder is laid on a species of wooden "horse," and a boy applies a string of molten glass round the dotted line. This he then knocks away, and applies the point of a cold iron rod to this heated ring. Instantly a crack runs round and the pontil is free. The glass cylinders cool very quickly. They are carried away two at a time, one under each arm, by girls, to another department. Here laid once more on horses of wood, a little fat coal dust is sprinkled along the lower part, and a stout red-hot bar of iron is worked backwards and forwards inside the cylinder for a minute, then a touch of a cold iron and the cylinder cracks from end to end; the workman gives it a tap with the flat of his hand, and one edge flies inside the other—thus, —lapping over by half an inch, so much is the glass in tension. The cylinders are then placed in cool ovens, and flattened out by a man with a block of hard wood on the end of a rod.

So much for the general character of the process. The width of the sheet is limited by the length of the cylinder; some of the best men produce cylinders as much as 6ft. long. The dexterity and skill with which a red-hot glass cylinder, weighing some 70 lb., is manipulated, must be seen—it cannot be realised from any description.

Much is heard about cheap labour in Belgium. It is certain that as far as the Mariemont Glass Works are concerned, labour is not cheap. The blowers are a very fine body of men. Great strapping lean fellows, with the muscles of the right arm curiously developed as compared with the left. The average earnings of the picked men who produce the long cylinders are £24 a month, or £6 a week. That of the next class is £18 to £20 a month. The lowest wages paid are to children, who get 65f. a month. It must not be forgotten that no Sundays are kept. The works run day and night from one end of the year to the other. Nearly all the hands, certainly all the blowers, are on piece work; and the regulation of the working hours is their affair more than that of the company. Many of the blowers have as much as £3000 invested. But all is not gold that glitters. The labour is so peculiar and so severe, that the number of men who possess at once the necessary skill and the requisite physique are very scarce. To all intents and purposes they are skilled athletes, and none of them are over forty-five years of age. After that they have to take a second place, making the short cylinders, and of course earning smaller wages. So far as we could learn, it seems that the wide glass makers do not possess the necessary skill until they are about twenty-eight or thirty, and do not retain the necessary strength and suppleness after they are forty. The girls, who are employed in large numbers, are fat, good-looking, and merry. The children, too, have nothing of an oppressed or hunted air; they are rather, on the contrary, disposed to be assertive, and they certainly earn more money than it is at all usual for children to get. It will be seen that eight-hour shifts are worked, but there is no law on the subject, nor any fixed rules. The matter is one of arrangement among the hands themselves. So long as the furnaces are kept going and the output is maintained, the company cares very little how the men do their piecework. There is no machinery of any kind in the place; the boilers are only used to supply steam for the air injectors. All the arrangements in the works are of a very superior description. The discipline is good, and the hands, taken all round, intellectual, comfortable, and well-to-do, by comparison with many other places.

About 12.15 a.m. the party left the glass works and trudged back through the rain to the station, whence the train conveyed them to Charleroi. Here they were joined by the party which had gone to Bascoup, augmented by a German contingent. In an upper chamber in the Bourse a splendid luncheon was served to over 500 persons at 12.30 p.m. A noteworthy feature was the music, supplied by the Fanfare du Circle d'Dagnelies, a band which is, we believe, held to be one of the best in Belgium. They played with a dash and *elan* which we have never heard equalled. "God Save the Queen" was splendidly rendered, and cheer followed cheer. Then came the "Brabançon," the national air of Belgium, which was encored. Then followed "Der Wacht am Rhein;" but it was noteworthy that no French air was played. *The* success of the day, however, was Wagner's "Entr'acte et Chœur des Fiançailles de Lohengrin." The speeches made were very few, very short, and very good. The luncheon was in every respect a success, to which the leader of the band, M. Dagnelies, largely contributed. The luncheon was given by Les Industriels des Bassins du Centre et de Charleroi, and reflects the greatest credit on all concerned. The 23rd of August will no doubt long be remembered by many an Englishman with pleasure. But the meal was a short one, the train waited to convey the party to the great works of Couillet. There were, as will have been seen from the programme, other places open, but the great body stuck to Couillet.



THE COUILLET IRON AND STEEL WORKS, BELGIUM

Some idea of the appearance and arrangement of the place may be gathered from the reproduction of a photograph on this page. The origin of the works dates back to the beginning of the century. In 1821 there was a forge and puddling furnace for the production of nail rod iron. In 1825 the production of pig iron was started on a small scale, in a little blast furnace erected at Hauchies, near Couillet. The success attained was such that, in 1828, a much larger furnace was put up. In 1834 rolling mills were added. In 1835, under the auspices of the Society for Promoting National Industry, the Société Anonyme de Marcenelle et Couillet was founded. The establishment at present employs about 5000 hands, and almost everything that can be made of iron or steel is produced. The blast furnaces are of the type usual in Belgium. The steel works are provided with Bessemer converters and two Siemens open-hearth furnaces, one of eight, the other of 15 tons capacity. In the rolling mills the most noteworthy feature is a splendid three-high mill, which was employed during our visit in making large building joists, which were turned out in lengths of about 60ft., and then cut into threes by a circular saw. The engine driving this mill is of the reversing type, with three horizontal cylinders, non-compound, and a modified Joy's valve gear. It is a splendid piece of work; we believe we are right in saying that there is not a three-cylinder rolling mill engine in England. The admirable smoothness with which the Couillet engine worked, with its three cranks at equal angles, commended it to those who saw it; and the example set by Couillet is, we fancy, certain to be followed. The Bessemer blowing engines are a fine job, but might be improved by augmenting the areas of the admission valves. The electric light is used all over the works.

We have said that almost everything is made at Couillet, and among others may be mentioned steel shot and shell, and Grüson cupolas in chilled cast iron. The engine works cover a good deal of ground; and in the locomotive department there stood end-to-end one of the little engines used for working steam trams and a very powerful engine for the Belgian State Railway. In the shops, however, we noticed nothing very noteworthy in the shape of tools, and the boiler work, although excellent, conforms to Belgian and not to the best English practice. We did not see a flanging press or a hydraulic riveting machine, and all the rivets are caulked as well as the rest of the boiler.

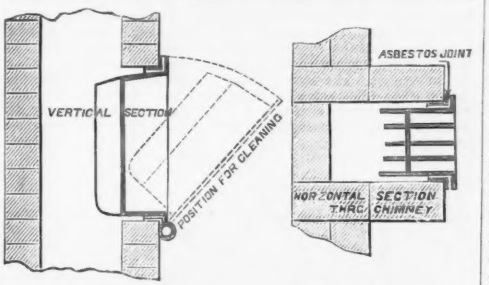
In all the steel works visited there is much in common, and lack of space this week prevents us from going into detail about the Couillet works. In our next impression we shall have a good deal to say concerning the Angleur Steelworks, much of which will apply generally to steel and iron making throughout Belgium. The Couillet works are supplied with coal from the company's mines at Marcinelle, Mont-sur-Marchienne, and Fiestaux, ably managed by M. Mockel. There are fifty-four seams worked, representing a total thickness of 25 metres. The average depth is 430 yards, and the deepest pit is 750 yards. There is at the works a complete coke oven plant, on the system of Smet and of Bruant. The coke is made in very narrow ovens, out of which it is pushed by a ram, worked by a steam engine. The plate mills of the company are at Châtelineau; but these works were not included in the excursion.

The company possesses in all five blast furnaces, 250 coke ovens, 60 puddling furnaces, 25 re-heating furnaces, a complete Martin-Siemens plant, 10 cupolas, 10 rolling mills, three foundries, three boiler shops, 100 forge fires, 14 locomotive engines, to say nothing of the colliery plant. In 1889 there were turned out products to the value of 15,000,000 of francs, or nearly one million sterling. The coal raised was 400,000 tons, and 68,000 tons of coke were made; 100 locomotives were constructed. The great three-high mill has since been added; but we have no precise data of the turnout in recent years. It is probably much what it was in 1889.

Very elaborate arrangements are made for providing pensions, schools, and medical aid; but these would deserve an article to themselves, which we may possibly publish at another time. In our next impression we shall deal with the visits paid on Friday to the works at Liége.

## KNIGHT'S HEATER OR THERMOSOTE.

THE Thermosote illustrated by the accompanying engraving is an apparatus based on the principle of conduction and radiation of heat. It has been invented to save some of the heat which has hitherto been wasted up the chimneys of kitchen ranges, and to utilise it for heating bedrooms above. The radiator or thermosote is let into the wall of the chimney, where it passes the room it is desired to warm. It is made of cast iron, the part containing the radiators being hinged as shown in the section, so as to be easily cleaned. In most cases it can be fixed by a bricklayer in a few hours. The heat trapped by it is sufficient it is said to make all the difference between a cold and a warm bedroom, and makes a fire unnecessary. A further advantage is that wherever the thermosote can be fitted into kitchen chimney walls, or into those of rooms in which a fire is burned through the winter, it does a great deal to make the house dryer. It is the invention of Mr. J. H. Knight, of Barfield, Farnham.



## LORIS' BULLET AND DAGGER-PROOF CUIRASS.

ON the occasion of the trial of Mr. Maxim's shield at the theatre of the Aquarium, we reported that Mr. Loris asked permission to fire at the cuirass first exhibited, and perforated t on the proper left side, it being only plated down the centre. Mr. Loris has, during the last few days, exhibited two cuirasses of his own in the theatre of the Crystal Palace. One of these is ½in. thick, and is intended to resist pistol bullets or dagger thrusts. The other, 2½in. thick, is to keep out the service rifle ammunition, and even steel bullets. The powers of both were very fairly tried. The smaller one was repeatedly fired at with pistols, and in case of any question as to the strength of the dagger thrust, the offer was made to any one of the audience, to try for himself. The heavier cuirass was fired at with the service ammunition and resisted penetration completely. The smaller cuirass was handed round to the audience who examined and handled it freely, and it was bent on the back of a seat to show flexibility. It was stated to contain no metal of any kind, and to consist of fibre whose character is kept secret. Recovered bullets, both steel and lead, were exhibited on request. They were more abruptly flattened than those which had been stopped by the Dowe cuirass, and they did not exhibit the pitted surface which was seen in the Dowe cuirass bullets. In fact, judging from the appearance, it might have been supposed that the bullets had entered some strongly resisting substance which was of a tough plastic character backed by metal. The steel bullet simply had its point flattened, the lead service bullet was set up in a smooth, shapeless lump, but it was not spread out as if it had struck steel abruptly. Whatever the non-metallic fibre is that is employed, it is differently treated from that in the Dowe cuirass, and is less suggestive of asbestos, but it is little use to guess further. Unquestionably the cuirasses were good ones, and would, we think, hold their own as to weight and power against any we have seen. It is impossible to speak absolutely as to relative powers without full trials, but these had the advantage in form and convenience. A man with the Maxim or the Dowe cuirass resembled a man walking with a sandwich advertisement. No great stress is to be laid on this beyond marking a further stage of manufacture, as the same material might be shaped better if not too thick. Mr. Loris undertakes to provide a revolver and dagger-proof jacket weighing only 6 lb. It is to be regretted that he could not have brought forward his cuirass when the public interest was excited, and not when it had cooled down considerably.

We have only noticed the trial of the cuirass. It was, however, one part of a programme exhibiting the powers of Mr. Loris as a marksman, and also of a very young girl, Altina, and these powers are very striking. After the usual shooting of egg shells, fixed in various positions round the head and body of a dummy figure by Mr. Loris and Altina, followed feats which now take place commonly, but against which we strongly protest, namely, the William Tell class of exhibition, that is, shooting eggs off the head and out of the hands of a living person. Altina is a singularly beautiful and graceful young girl; had it been generally known what a sensational performance was being enacted, probably a much larger audience might have been gathered. It is no doubt most absorbing to watch a succession of apparently hairbreadth escapes experienced by so interesting a maiden, but that does not make it justifiable. An experienced man, at all events, knows the risk he incurs if he exposes himself, like Herr Dowe, who has recently paid for his confidence by being wounded, or Maxim, who has a wife who makes him promise not to stand fire; but a child cannot judge of possible contingencies. We have used the word "apparent" hairbreadth escapes, because we do not want to overestimate the risk run. Altina put on what appeared to be a silk skull cap, with a point perhaps 5in. long. This cap we were allowed to examine on our protesting as to the risk run, and we were glad to see that it was steel, and we hope proof against pistol balls. This gave in all perhaps 7in. margin for the bullet to go low before killing the girl, and no doubt it is very unlikely at the few yards distance of the firing, that so perfect a marksman as Mr. Loris would fire a bullet 7in. lower than he intended.

TESTS of the new pneumatic guns have been carried out at Sandy Hook. In the first experiment a charge of 500 lb. of dynamite was fired a distance of a mile and a-half. According to the *Times* there was a tremendous explosion, and a column of water was raised 100ft. high. In the next test a charge of 50 lb. of dynamite fell at a distance of three and a-half miles. Should the official tests be considered successful a dynamite gun battery, consisting of two 15in. guns and one 8in. gun, will be mounted near the extreme point of Sandy Hook, so as to sweep the channel leading to the lower bay. A continuation of the experiments consisted of speed tests, the best result being ten shots in fifteen minutes. By the contract forty minutes were allowed. The other conditions imposed have nearly all been fulfilled. The most important of these were that it should be able to project a shell containing 500 lb. of high explosive to a range of 2000 yards, one containing 200 lb. to a range of 3550 yards, one containing 100 lb. to a range of 4500 yards, and one containing 50 lb. to a range of 5500 yards.

# NOTES ON ELECTRIC POWER, WITH SPECIAL REFERENCE TO WORKS DRIVEN BY ELECTRICITY IN BELGIUM.*

By D. Selby-Bigge.

Last May the author of these few notes had the honour of submitting to the Iron and Steel Institute a paper on "Electricity as a Motive Power in the Iron and Steel Industries," in which he treated the subject somewhat closely, and at considerable length. Three months having barely elapsed, it would be difficult for him to find sufficient new matter from which to write an entirely new paper on the same subject without running the risk of frequently repeating himself; he will therefore abandon any idea of writing a fresh paper, and will ask the members of this Institute to consider the following notes in the light of a short supplementary communication relating to what has already been done in this country in the way of practical applications of electric power.

The attention of electrical engineers in England has of late been so much taken up with the design, laying down, and starting to work of central electric lighting stations in our different towns, and electric lighting work in general, that the question of applying electricity for power purposes has certainly not received at their hands the same amount of investigation that it has from our Belgian and continental friends. Such countries as Switzerland and Northern Italy are exceptionally situated as regards natural sources of power, such as water, and it was only to be expected that they should take a lead in transmitting electricity to be utilised for power purposes in the driving of factories, &c.; and, indeed, a considerable amount of work has already been carried out by the Oerlikon Company, Messrs. Ganz, of Buda Pesth, Messrs. Siemens and Halske, of Berlin, and many other well-known firms, in this direction.

The economy to be derived from driving factories or works electrically, utilising water as our source of power, requires but little comment from the author, as the advantages cannot but be self-evident to any engineer; but electricity has done much to enhance the commercial value of water-power. Hitherto, valuable power in the shape of waterfalls, situated in distant hills and inaccessible places, has been allowed to run to waste for years, and would be doing so still, were it not for the advent of electricity, which has provided such simple and economical means for the conversion of this power, its transmission over enormous distances with trifling loss, and its application to almost any industrial undertaking at the far end of the line. The great Niagara scheme will doubtless furnish the best illustration of such a utilisation of force. The author has often thought that in countries where no very large water powers exist, such as the powers available in our counties of Lancashire and Yorkshire, turbine dynamos might be laid down at the different falls, and the power distributed to one collective centre, where the greatest demand for current would arise; in this way many falls, which though formerly employed in the driving of factories, have been abandoned owing to their distance from main lines, and high railway dues, would again be brought into use. There are, however, many, if not the majority of countries, in which water-powers are few and far between, and the next best means for the economical driving of works has to be considered. The author has already pointed out, and laid great stress upon, the utilisation of waste furnace gases for producing steam in the boilers connected with the electric generating plant; in those cases where such a course is feasible, the cost of production per unit of electrical energy must necessarily be very low, and in order to arrive at a figure, it would be necessary to put a fixed value upon the quantity of waste gases used for firing the boilers, providing steam for running the electric generators at a fixed load, and for a given time. The cost of wages, oil, waste, upkeep, and incidentals could be arrived at in the ordinary manner.

The question of cost of production of electricity to be employed in driving engineering works, steelworks, shipyards, and factories of any description, must necessarily be of the first importance when considering an application of electric power; and in order to convey an accurate idea of the probable cost, the author will refer to some of the Board of Trade returns of electric lighting stations in England for 1893, showing what has been the cost of production to different companies.

| Name of company. | Total H P capacity of engines | Cost of production and distribution per unit delivered to consumers. | | | | |
|---|---|---|---|---|---|---|
| | | Coal | Oil, waste, water, engine-room, stores and carbons. | Salaries of engineers and wages | Repairs and maintenance. | Total. |
| | | d. | Low tension.<br>d. | d. | d. | *d.* |
| Liverpool .. .. . | 1800 | 0·93 | 0·16 | 0·88 | 0·14 | 2·11 |
| Westminster .. .. | 4530 | 0·78 | 0·19 | 0·95 | 0·35 | 2·27 |
| | | | High tension. | | | |
| Newcastle district . | 1200 | 0·83 | 0·28 | 0·85 | 0·14 | 2·10 |
| Newcastle supply .. | 1200 | 0·63 | 0·18 | 0·77 | 0·53 | 2·11 |

From the above table it will be seen that the cost of production, including coal, oil, waste, water, salaries of engineers and wages, repairs and maintenance, amount, in the case of the Liverpool company, to 2·11d., and in the Newcastle companies to very much the same figure. The Westminster company has a cost of production of 2·27d. These figures are about the lowest that have yet been attained in England, where coal has been used in the production of electricity. From the figures given above, the ratio of the expenditure for coal, compared with the total cost of production, can be deducted, and will be found very interesting. The Newcastle Supply Company has the very low figure of ·63 out of 2·11 set down for coal, but coals are sometimes cheap at Newcastle, and this is perhaps an exceptional case. It is hardly correct to compare an electric power station with an electric lighting station, but it may be taken that in power work, where it is possible to use larger generators than is usually advisable in electric lighting stations, the cost of production should be rather less than more, and when waste furnace gases are available the cost of production should certainly not exceed one penny per unit of 1000 watt hours.

In laying out new works which are intended to be driven electrically, or even in remodelling old ones, it is necessary to have a correct knowledge of what working efficiencies one may reasonably expect from various sized dynamos and motors, in order to be able to form an exact opinion as to the power it is necessary to provide in order to drive the works. The author's own experience in these matters would lead him to suggest that for large-sized power generating dynamos of 300-horse power, 500-horse power, 800-horse power, and 1000-horse power, an efficiency of between 90 per cent. and 92 per cent. may be expected. In the case of motors, the following:—

| | | | | | | |
|---|---|---|---|---|---|---|
| For | 3-horse | power | motors | an efficiency of | 78 | per cent. |
| ,, | 5 | ,, | ,, | ,, | 80 | ,, |
| ,, | 8 | ,, | ,, | ,, | 84 | ,, |
| ,, | 11 | ,, | ,, | ,, | 86 | ,, |
| ,, | 16 | ,, | ,, | ,, | 87 | ,, |
| ,, | 20 | ,, | ,, | ,, | 87 | ,, |
| ,, | 40 | ,, | ,, | ,, | 89 | ,, |

As to the loss in transmission through heating of cables, leakage, &c., this should not exceed 3 per cent. in cases where the motors are situated at distances from the generating source of not more than 300 yards, and 5 or 6 per cent. where the distance does not exceed 500 yards. This, however, cannot be taken as a hard-and-fast rule for every case, but it will be found to apply in the case of most works, and the expenditure of copper in the mains will not be found to be prohibitive.

The main and great advantages to be derived from electric driving in works may be summarised as the following:—(1) The concentration in one highly economical plant of the generation of power for the whole of the works, and great reduction in coal consumed per unit of work done. (2) Reduction in wages, owing to the very small number of officials required in connection with such a plant. (3) Transmission of the energy generated, with very trifling loss, to the different parts of the works. (4) Absence of main shafting, countershafting, pulleys, bearings, and belts, and heavy cost of upkeep in connection therewith. (5) Absence of long lengths of steam pipes, and losses due to condensation. Absence of scattered and separate boilers. (7) Absolute control over the economical running of the works owing to the self-indicating nature of electric motors, and the immediate detection of any undue losses which so often occur in mechanical forms of power transmission. (8) Great economy in work of an intermittent nature and varying loads, a direct proportion between the indicated horse-power of generating engine and work given out by motors being obtained. (9) Very small cost and size of foundations involved in works driven electrically. (10) Great facility for alterations and extensions, without any modification being necessary to the original plant.

The points referred to above are perhaps the most salient, but there are many others which appear on the surface in practical work. The whole contention of the author in advocating electricity as the right and proper agent for operating new works, and as a means whereby old works can be remodelled, may be summarised by the one word "economy." In no country, perhaps, have engineers looked more thoroughly and closely into the economics of electricity as applied to power work than in Belgium, and the author trusts that reference by him to works driven by electricity in this country may not be out of place at the present meeting. In the first instance he would refer to an installation which has now been at work for some considerable time, viz., that of the National Arms Factory, at Herstal, near Liége. To give a full account of these important works would necessitate a paper to be written solely for this purpose; the author will therefore confine himself to giving a brief description of them, with a few figures as to results obtained. Mr. Leon Castermans, in a communication which was published in the *Revue Universelle des Mines*, stated that towards the end of 1886 the principal arms manufacturers at Liége formed a syndicate with the intention of laying down works to carry out in a rapid manner important orders for guns. A company was eventually formed, under the title of the Fabrique Nationale d'Armes de Guerre, end an order was given to this company for 150,000 to 200,000 rifles. In order to carry out this work the society determined to lay down works provided with all the latest improvements and up to date in every respect. The works were to be capable of turning out 250 rifles in twelve working hours. Two years were allowed for completing the installation of these works, and two years for the construction of the rifles. In 1890 a plan was submitted for laying down works—all the different means of power transmission were minutely gone into, and electricity was eventually adopted as the sole power to be employed for driving the works. At this time there were no works of such importance running solely by electricity, and a precedent did not exist. The Compagnie Internationale d'Electricité went, however, most closely into the matter, with the result that they were able to offer to the syndicate absolute guarantees for successful working, which have since been fully realised. When these works were started the Compagnie Internationale d'Electricité laid down—

| | | | | | |
|---|---|---|---|---|---|
| 9 | motors of | 16-horse power | = | 144-horse power | |
| 2 | ,, | 21 | ,, | = 42 | ,, |
| 2 | ,, | 37 | ,, | = 74 | ,, |
| | | Total .. .. .. | | 260 | ,, |

For each motor the Compagnie Internationale d'Electricité guaranteed—for the 16-horse power, a commercial efficiency of 87 per cent.; for the 21-horse power, a commercial efficiency of 87 per cent.; for the 37-horse power, a commercial efficiency of 89 per cent., so that the available power would be produced by an initial power of—

$$\frac{144}{0·87} = 165·5$$

$$\frac{42}{0·87} = 8·34$$

$$\frac{74}{0·89} = 83·1$$

$$\text{Total} \; .. \; .. \; .. \; .. \; 296·9\text{-horse power.}$$

As the loss by canalisation would not be greater than 2 per cent.,

$$\frac{296·9}{0·98} = 303\text{-horse power}$$

at the dynamo terminals. In addition to the above there was a large amount of lighting to be considered, and the power eventually adopted was an engine and dynamo combined of 500-horse power. This dynamo is of the shunt-wound type, and suitable for a tension of 125 volts; there are twenty pole-pieces formed in the form of a circle round the armature, and allowing a play of 6 millimetres to the latter. The armature, on account of its large dimensions, some 17ft., had to be built up *in situ*. The current is taken from two commutators, one on either side of the armature, by eighty metallic brushes; the current is taken away to the main distributing switchboard by four underground cables. The commercial efficiency—that is to say, the ratio between the electric energy available and the energy transmitted to the shaft by the engine—was guaranteed to be 90 per cent. The carcase, which is in steel, of the dynamo weighs 10 tons; the armature alone weighs 10 tons; the copper in the magnets weighs two tons; and the armature coils 600 kilos. The particular characteristic of this dynamo is that not only is it driven direct by the steam engine, but that the armature itself forms the fly-wheel of the engine. The motors about the works drive different line shafts. The efficiency of transmission, that is to say, the ratio between the power available and the effective horse-power developed by the steam engine, is given by the product of the three efficiencies—

98 per cent guaranteed for the dynamo.
98 per cent. guaranteed for the conductors.
87 per cent. guaranteed for the motors.
= 76·6 per cent.

The installation at Herstal has now been running continuously for three years, and until recently the entire works depended solely on the running of this single dynamo, both for light and power. About 2000 hands are employed at the works. Up to the present, the large dynamo has never been the cause of the cessation from work for a single minute. The installation has of late been considerably extended, and an additional 300-horse power plant has been laid down. The speed of the large engine and dynamo is only sixty-six revolutions per minute. The engine employed, being of the Corliss compound condensing type, was built by Messrs. Van de Kerkchove, while the dynamo was constructed by the Compagnie Internationale d'Electricité, under the direction of Mr. H. Pieper.[*] The 300-horse power plant consists of a combined Willans engine and Pieper dynamo, running at about 350 revolutions per minute, and it is interesting to compare the results obtained with these two engines. The efficiency of the Corliss combined plant—that is to say, the efficiency of the engine and dynamo taken together under full load—is about 77 per cent. The dry steam consumption of the engine per indicated horse-power per hour = 14·34 lb. The dry steam consumption of the engine per electrical horse-power per hour = 18·75 lb. On the other hand, we get the highest efficiency from the quick running plant. The efficiency of the Willans engine and dynamo combined at full load is about 85 per cent. Dry steam consumption per indicated horse-power per hour = 16·03 pounds. Dry steam consumption per electrical horse-power per hour = 18·19 pounds. Any one visiting the installation at Herstal cannot fail to be struck with the wonderful organisation in the works, and the result obtained during the past three years in driving these works electrically has been an unqualified success. At the zinc works of the Vieille Montagne Company, near Jemeppe, a large electric power installation has recently been laid down. The works were formerly driven by a large number of steam engines, which took from 60 lb. to 88 lb. of steam per indicated horse-power per hour to drive them, and required a number of enginemen to attend to them.

The question of driving the works by means of hydraulic power, compressed air, and electricity were examined in turn, and it was decided to lay down a regular central power station, and to drive the works by means of electricity. The station is placed alongside the railway, so that coal may be brought right up to the boiler-house by truck. Three Babcock and Wilcox boilers have been laid down—one acting as spare, while the other two provide steam for a 600-horse power compound condensing engine, on the Friekart system, built by the Société Cockerill, at Seraing, which drives direct a Pieper fly-wheel dynamo of 600-horse power at a speed of 80 revolutions per minute. The dynamo is wound for a pressure of 500 volts. Every provision is made in the engine-house for a second section of 600-horse power, of a similar character to the first. The water from the Meuse, situated at a distance of 2700 metres from the generating station, is pumped to the works by a 45-horse power motor, and the current is further utilised in operating two electric wharf cranes for loading and unloading the boats. The motors laid down at present are of the following sizes:—

| | | | | |
|---|---|---|---|---|
| 5 | motors | of | 1 | horse-power. |
| 7 | ,, | ,, | 2 | ,, |
| 6 | ,, | ,, | 2½ | ,, |
| 6 | ,, | ,, | 5 | ,, |
| 4 | ,, | ,, | 7 | ,, |
| 2 | ,, | ,, | 10½ | ,, |
| 4 | ,, | ,, | 14 | ,, |
| 2 | ,, | ,, | 45 | ,, |
| 1 | ,, | ,, | 64 | ,, |

It is now proposed to add the following motors:—

| | | | | |
|---|---|---|---|---|
| 1 | motor | of | 80 | horse-power. |
| 1 | ,, | ,, | 14 | ,, |
| 5 | ,, | ,, | 1 | ,, |
| 1 | ,, | ,, | 10 | ,, |

The current is taken from the main generator to the main power switchboard, and is carried through eighteen circuits to distributing boards in the works. In addition to the power, there are 75 arc lamps and 500 incandescent lamps in the works. As the tension of 500 volts is too high for the latter, a continuous current transformer is used, which reduces the pressure to 100 volts. During the day time this transformer charges a battery of accumulators. The motors drive, amongst other things, joiners' shops, forges, fans, machine tools, saws, pumps, lifts, washing machines, crushing machines, brick-making machines, &c. &c.

*Efficiency of the Installation.*

| | | | |
|---|---|---|---|
| The efficiency of the | steam engine is .. .. .. .. | 90 | per cent. |
| ,, ,, | generating dynamo .. .. .. | 90 | ,, |
| ,, ,, | circuits at full load .. .. .. | 98 | ,, |
| ,, ,, | motors .. .. .. .. .. .. | 86 | ,, |

which gives a total efficiency of 0·685. Such are briefly the outlines of the Vieille Montagne installation. Electric power installations have also been laid down, and are working most successfully, at the Royal Arms Factory at Liége, where the coal consumption has been much reduced; at the works of Messrs. Dietrich and Co., at Luneville, and at the celebrated glass works of the Val-St.-Lambert. At this last place there are six motors, eighty-six arc lamps, and 1100 incandescent lights.

# THE MOST ECONOMICAL TEMPERATURE FOR STEAM ENGINE CYLINDERS, OR HOT *v.* COLD WALLS.*

By Bryan Donkin, M.I.C.E.

(*Concluded from page* 179)

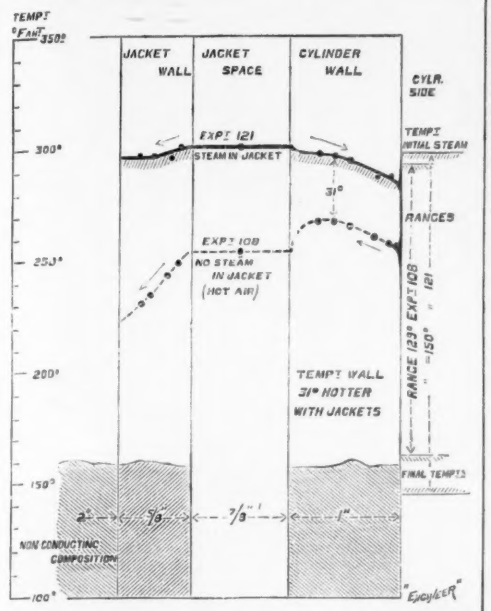
*Experimental results.*—The following short abstracts are from a paper detailing a series of some eighty experiments, lately accepted for publication by the Institution of Mechanical Engineers. Permission has been granted to quote such portions as bear upon the question of the advantages of hot, and disadvantages of cold cylinders. These experiments were made on a single-cylinder engine, 6in. diameter by 8in. stroke, expressly designed for experimental research. The engine could be worked so as to vary considerably the temperature of the walls, and was made to run condensing or non-condensing, jacketed or non-jacketed, single or double-acting, at different expansions, with saturated or superheated steam in the cylinder or jackets. Only one set of conditions, however, was varied at a time. Two experiments—first series—were made with 50 lb. of saturated steam, with the cylinder non-jacketed and condensing, at 220 revolutions per minute, double-acting. In these tests the only condition varied was the number of expansions, from 5¾ at $\frac{1}{12}$ cut-off to 2½ at $\frac{5}{16}$ cut-off. The cylinder walls in both cases were colder than the initial steam. The steam consumption per indicated horse-power hour fell from 43½ lb. at the earlier cut-off to 35½ lb. at the later. The temperature range of steam in the cylinder varied from 135 deg. to 128 deg. The indicated horse-power varied from 4¾ to 7½. As the number of expansions diminished from 5¾ to 2½, a greater weight of steam per hour passed through the engine, namely, 184 lb. and 269 lb., and the temperature of the walls was correspondingly increased from 233 deg. to 264 deg. In other words, the difference of temperature between the initial steam and the internal surface for the walls was reduced from 65 deg. to 31 deg. respectively. The rate of condensation during admission per square foot hour diminished considerably with the increase of wall temperature, from 515 lb. to 264 lb. Comparing the two experiments, when the difference between the temperature of the steam and that of the cylinder walls was decreased 34 deg., and the temperature of the walls raised, the result was not only to reduce the initial condensation one half, but to produce an economy of steam consumption of 18½ per cent. The thermal efficiency—or percentage of heat converted into power to the total heat received by the engine—was increased from 5·3 per cent. to 6·6 per cent., or 25 per cent. The percentage of steam present at cut-off and release were both considerably raised; all these advantages were obtained, although the number of expansions was diminished. There were eight experiments with different expansions in this series, but only two are given, as all the results are consistent.

In the next two experiments—third series—working with 50 lb. saturated steam, non-jacketed, double-acting, at 220 revolutions, and non-condensing, the only condition varied was the number of expansions, from 4¾ at ⅛ cut-off to 1¼ at ¾ cut-off. The indicated horse-power varied from 3 in the one to 8·4 in the other. The cylinder walls were colder than the steam by 54 deg. and 16 deg. respectively. The steam consumption per indicated horse-power hour was 62 lb. and 44·4 lb. respectively. The range of steam temperature in the cylinder was about 85 deg. The temperature of the cylinder walls increased in these experiments, with the quantity of steam per hour passing through the cylinder—183 lb. and 373 lb.—from 246 deg. with the greater, to 282 deg. with the smaller expansion, or a rise of 36 deg. The condensation during admission per square foot fell from 440 lb. to 105 lb., or say four times as much with colder walls. The thermal efficiency increased from 3·8 to 5·4 per cent. Comparing these two non-condensing trials, an increase of 36 deg. in the cylinder wall temperature resulted in a reduction of 28½ per cent. in steam consumption; the initial condensation with colder, being four times greater than with hotter walls. The thermal efficiency was 42 per cent. greater with warmer walls. The percentage of steam present at cut-off and release was considerably increased. These advantages were obtained with a decrease in the number of expansions. There were six experiments in this series, but only two are given.

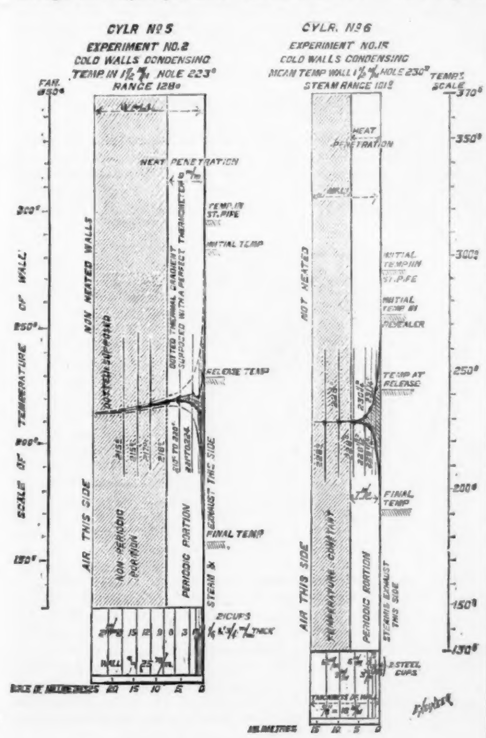
---

* Paper read before the British Association at Oxford.

We now come to two experiments—fourth series—working with 50 lb. of saturated steam non-jacketed, single acting, and condensing. The number of expansions was varied from 4¾ at ⅕ cut-off, to 1¾ at ½ cut-off, speed 227 revolutions. The indicated horse-power was 2 in the first case and 4 in the second. Steam per indicated horse-power hour 56 lb. and 46 lb. respectively, and steam temperature range about the same. The temperature of the cylinder walls was raised with the quantity of steam per hour passing through the engine—110 lb. and 190 lb.—from 223 deg. in the former to 266 deg. in the latter, or an increase of 43 deg. The amount of initial condensation per square-foot hour decreased from 576 lb. to 336 lb. The thermal efficiency increased from 4 to 5 per cent. The walls were 73 deg. cooler than the initial steam in the first, and 32 deg. in the last trial. Comparing these two experiments under the conditions given, 43 deg. increase of cylinder temperature resulted in 18 per cent. economy of steam consumption, 25 per cent. greater thermal efficiency, and 42 per cent. less initial condensation. The percentage of steam present at both cut-off and release was largely increased. Here, again, the above advantages were obtained with a decrease in the number of expansions. The plotted results of the four experiments of this series—two of which only are given—are consistent, and verify the better results with hotter walls.

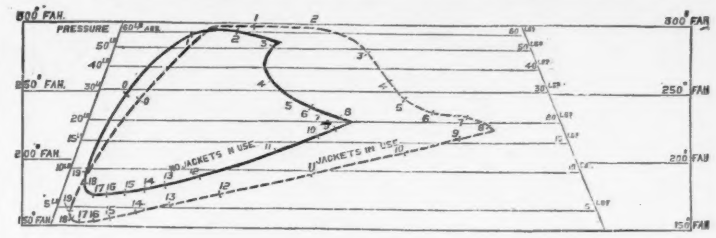


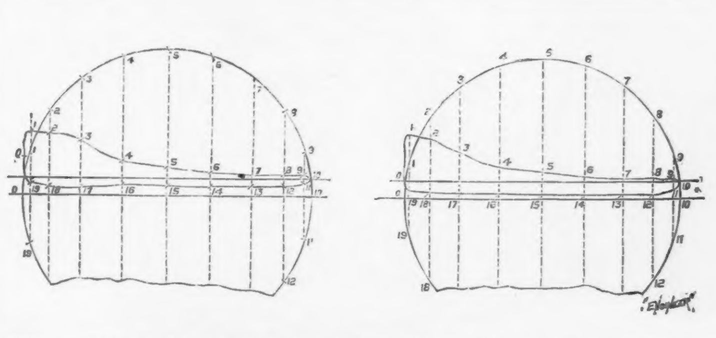
Two experiments—Series 6—were made with 50 lb. saturated steam, cylinder non-jacketed, non-condensing, and single-acting; revolutions, about 220; number of expansions, three at ⅓ cut-off in the first, and 1⅓ at ¾ cut-off in the second. This was the only difference in these two experiments. The walls were cooler than the steam 49 deg. at ⅓ cut-off giving 1⅓ indicated horse-power. and 22 deg. at ¾ cut-off with 3⅓ indicated horse-power. The pounds steam used per indicated horse-power hour were 80·7 and 60·4 respectively. The range of steam temperature was about the same. The cylinder wall temperature rose from 246 deg. in the first to 276 deg. in the second, and the thermal efficiency from 2·8 per cent. to 3·8 per cent., both increasing with the quantity of steam passing through the engine per hour—112 lb. and 202 lb. On the other hand, the initial condensation per square-foot hour fell from 311 lb. to 139 lb. Comparing the two experiments, 30 deg. higher cylinder wall temperature reduced the initial condensation about one-half, decreased the steam consumption per indicated horse-power 25 per cent., and raised the thermal efficiency 35 per cent. The percentage of steam present at cut-off and release was much greater.



This gain was obtained with much fewer expansions. All the experiments in this series confirm the above results.

Two experiments—ninth series—were made with and without steam jackets, double-acting and condensing. In these trials with saturated steam at 50 lb. pressure and speed 218 revolutions, the same cut-off was used, viz., $\frac{3}{16}$, and the number of expansions kept constant at 3¾. The only condition varied was that the engine worked in the one case with no steam in the barrel and cover jackets—in other words, with hot air in the jackets—and in the other with steam at 50 lb. pressure in them. The indicated horse-power were 6·6 and 6·8 respectively. The consumption of steam per indicated horse-power hour was 41¼ lb. without, and 28⅓ lb. with jackets in use, the steam temperature range being about the same in both. The temperature of the cylinder walls was 255 deg. without jackets and 284 deg. with the jackets working; the rate of initial condensation per square-foot hour was 460 lb. and 217 lb. respectively; the thermal efficiency was 5·7 and 8·1 per cent. Walls colder than initial steam, 42 deg. and 14 deg. respectively. Thus in these two experiments at the same speed, cut-off, and steam pressure, and all other conditions being exactly similar, raising the temperature of the walls 29 deg., by working with steam in the jackets, gives the following advantages:—Initial condensation diminished one-half, gain in steam consumption 31 per cent.; thermal efficiency increased 41 per cent.; steam present at cut-off and release increased about 50 per cent.





Many other experiments were made, all at the same cut-off with and without steam jackets in use. The number of expansions was varied in each, but only after the set of two tests had been made, to determine the different economy of steam jackets at different expansions. An increase of economy with the hotter walls was always verified, the thermal efficiency was greater, and the rate of condensation very considerably reduced, with an increase in the percentage of steam present at cut-off and release. In another set of experiments upon small cast iron cylinders, mostly 5½in. diameter, an account of which was published in the "Proceedings" of the Institution of Civil Engineers, vol. cxv., the temperatures of the cylinders were also considerably varied. The chief object of this series was to determine the relation between the temperature of the cylinder wall and the amount of steam condensed per hour per unit of internal surface. The experiments were made at constant volume without piston, with about 50 lb. pressure of steam, and at 35 fillings per minute. Some forty experiments were carried out in all, condensing and non-condensing, with saturated and superheated steam. The wall temperatures were varied from 218 deg. to 348 deg. Fah., the temperature of the steam being kept constant at 297 deg., and with a cylinder-wall temperature of 218 deg. and saturated steam of 297 deg. Fah. —or the walls colder than the steam by 79 deg.—43½ lb. of steam. were condensed per hour per square foot of internal surface. With the highest wall temperature in these experiments, viz., 348 deg. Fah., using superheated steam, the minimum amount of condensation was obtained, only 1·3 lb. of water per square foot hour. The proportion between the internal surface in square feet and the volume in cubic feet was also varied. It was found that superheated, as compared with saturated steam, invariably resulted in much less condensation, and the walls were always found to be hotter. This was probably the chief cause of the diminished condensation and the increase of economy. The heat penetration into the metal walls varied much, according to their temperature. With cold walls at about 230 deg. it was about 8 mm.; with hot walls at a temperature of about 330 deg. it was only about 2 mm. The total steam used was measured in each experiment, and indicator diagrams were always obtained. From the difference between the actual steam consumption and that shown by the diagrams at release, in each experiment, the quantity of steam condensed was deduced. The indicator diagrams were much larger with the hotter than with the colder walls, or, in other words, much less condensation took place. In a few experiments the internal surfaces were varnished, and this was found to reduce condensation, the amount of steam present, both at cut-off and release, being greater with the varnished walls. A heat balance was made in each test. Less heat penetration into the walls always corresponded with less internal condensation. A description and drawing is appended of the condensation of steam in a steam jacket, giving the appearance of the drops formed.

*Temperature—Entropy diagram.*—A drawing is appended showing the diagram of two tests on the experimental engine, one with and one without, steam in the jackets. This diagram follows Mr. McFarlane Gray's and Captain Sankey's method, with the addition of twenty points for twenty equal times of the crank pin. Such diagrams show well the exchanges of heat between the steam and the walls. The temperature of the cylinder walls has a greater effect with small than with large cylinders, as the ratio of surface to volume is greater; this is verified by experiments on steam jackets, which give better results in smaller than in larger engines, both running at the same speed. The various tests on the experimental engine mentioned above lead to the conclusion that the range of steam temperature in the cylinder per stroke has much less influence on the consumption of steam than the temperature of the wall. In a steam engine a higher as compared with a lower speed generally means a greater weight of steam passing through the engine per hour, and more economy; the reason being that this additional weight of steam increases the temperature of the cylinder, and produces less condensation. Watt some 130 years ago wrote:—"On reflecting further, I perceive that in order to make the best use of steam it is necessary that the cylinder should be maintained always as hot as the steam which enters it." Such logical reflections soon resulted in his famous invention of the steam jacket. Professor Ewing in his interesting new work on the steam engine, just published, says:—"As steam fluctuates in temperature with phases of admission, expansion, and exhaust, there is a complex give and take of heat between it and the metal it touches, and the effects of this have an enormous influence in reducing the efficiency by increasing the consumption of steam." Professors Kennedy, Cotterill, Unwin, Boulvin, Dwelshauvers-Dery, and others, including D. K. Clark and Lieutenant-Col. English, have written on these important and complicated exchanges of heat between steam and metal. In addition to this, there is the effect of the water drops and films, &c. Hirn was the first to study and describe these phenomena accurately. It is the difference of temperature between the steam and the metal that is the chief cause of the rapid transfer of heat during a stroke; the "head" of heat is also constantly varying, and the ratio of surface to volume changes rapidly with the various positions of the piston.

*Summary.*—The above paper, and the tests on the experimental steam engine, with cold and hot walls, may be very shortly summarised, as follows:—The most uneconomical results were always obtained when the cylinder was colder than the entering steam, producing considerable initial condensation. Drops of all sizes were formed up to 3 mm. diameter, running down the cold surfaces, and there was considerable depth of heat penetration into the walls. During each stroke heat was given up by the steam to raise the temperature of the internal surfaces, after their exposure to the exhaust temperature. At cut-off and release there was a great deal of water in the cylinder.

The most economical results were always obtained when the cylinder was at nearly the same temperature as that of the entering steam, with much lower rates of condensation. The drops were very much smaller in size. The penetration of heat into the metal walls was much less, and a smaller amount of steam was required to heat the innermost surfaces after they had been cooled by the condenser. The percentage of steam present at cut-off and release was very much increased.

*Note of the results of condensation of steam, giving the formation of drops on glass and metallic walls, as seen through a glass steam jacket, with 20 lb. and 50 lb. pressure of steam.*—After a drop, about 5 mm. diameter, has run down the vertical cast iron walls, its path looks nearly dry. The formation of the finest particles of water or globules, say $\frac{1}{20}$ mm. diameter, is next seen on the same path. These then very gradually increase in size from $\frac{1}{10}$ to ⅕ and to ½ mm. diameter. The drops, irregularly shaped, next run together until they become 4½ to 5 mm. wide. After this they fall by gravity, dragging other smaller drops on their path. These drops have been photographed. On the horizontal metallic surfaces the same formation of drops takes place. With greater transmission of heat there is greater condensation, and the drops run down more frequently. There is no uniform film on the surfaces, but drops are produced gradually increasing in size and then running down. Note.—All temperature in Fah. degrees.

THE RUSSIAN GOVERNMENT are desirous of placing a contract for the building of two large steamers for the transport of rails. After five years' service the Government will purchase the steamers at cost price.

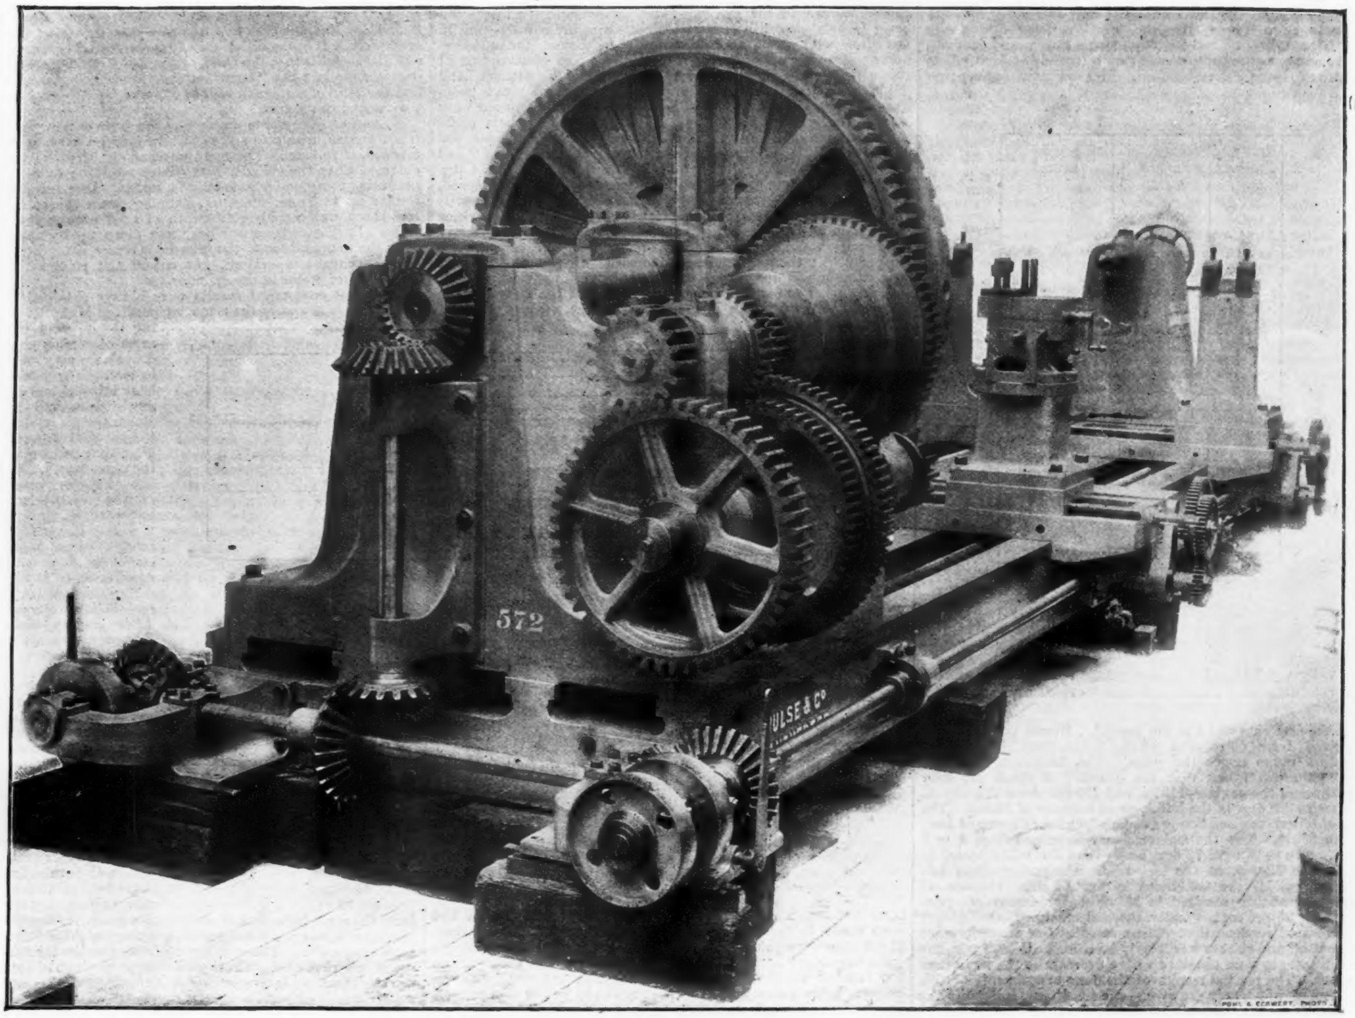
WHITWORTH SCHOLARSHIPS.—The following is a list of candidates successful in the competition for the Whitworth Scholarships and Exhibitions. Scholarships, tenable for three years: John Ball, James H. Smith, Harry Verney, Charles F. Smith, £125 a-year each. Exhibitions, tenable for one year: Frank Fisher, William M. Thornton, John W. Hinchley, William D. Young, Alexander L. Mellanby, William T. F. Trunchion, Henry Deanesly, William T. Swinger, Arthur W. Ashton, Arthur E. Mascall, William Rosbotham, Joseph J. Kirwin, Charlie W. Cairns, John W. Button, Sydney Eraut, Charles E. Pickles, Richard G. Allen, Alexander Craig, Thomas S. Usherwood, Walter Eraut, Lewis E. Limming, Sidney E. Lamb, Francis J. Russell, Edgar R. Sutcliffe, George F. Hambly, William Gore, Thomas S. Cockrill, William H. James, Harry J. Peachey, James N. Boot, £50 each.

DEATH OF MR. HENRY FAIJA.—We regret to announce the death, on August 21st, of Mr. Henry Faija, whose name is so well known in connection with cement industry. Mr. Faija was a member of the principal engineering and learned societies, viz., the Institution of Civil Engineers, Institution of Mechanical Engineers—1869-1889—British Association, Royal Institute of British Architects—Honorary Associate—Society of Arts, and Society of Engineers, of which latter body he was Vice-president at the time of his death, and but for his untimely removal would have succeeded to the chair in due course. He at various times contributed papers to all the above Societies on the subject of which he had made a special study, and was awarded premiums by the Society of Engineers for papers read before that body in 1888 and 1889. The latter papers were prepared with the object of combatting the "magnesia" scare which occurred at that time owing to the Aberdeen failures, and conclusively proved that the supposed destructive effect of sea water on a properly manipulated cement concrete was a scare and nothing more. In 1881 he wrote a treatise entitled "Portland Cement for Users," which has since run through more than one edition. The work of his office and laboratory will be continued for the benefit of the bereaved family.

DREDGING THE MERSEY BAR.—According to the recently-issued annual report of Mr. G. F. Lyster, engineer to the Mersey Docks and Harbour Board, upon the general state and progress of the Liverpool and Birkenhead Docks, the sand pump dredgers Brancker, and Nos. 5 and 7, were continuously dredging at the bar and shoal parts of Crosby Channel. The total quantity of sand removed during the twelve months was 4,707,920 tons, of which 4,407,150 tons was from the bar, and 300,770 tons from the Crosby Channel—at which Nos. 5 and 7 were exclusively engaged for about five months, and the Brancker at certain times when prevented by weather from working at the bar. The total quantity of sand removed from the bar since the commencement of operations was 6,845,860 tons. The depth of water within the buoyed channel—1000ft. wide according to the latest soundings—was not less than 20ft. in any part at low water extreme spring tides. For a space of 500ft. wide outside the buoys, on the south side, there were not any soundings under 19ft.; and for a space of similar width outside the buoys on the northern side the least depth was 15ft. The Brancker during the year's continuous working came fully up to the expectations formed from her construction and size, being able to remain at work on the bar during weather which prevented the smaller vessels from working. The time of filling a load varied, according to the nature of the material raised; but it has been done in thirty-five minutes. In one period of twenty-four hours 39,000 tons, and in a week of five and a-half days, 183,000 tons of sand were removed.

# QUADRUPLE-GEARED DUPLEX CRANK LATHE

MESSRS. HULSE AND CO., MANCHESTER, ENGINEERS



## QUADRUPLE-GEARED DUPLEX CRANK LATHE.

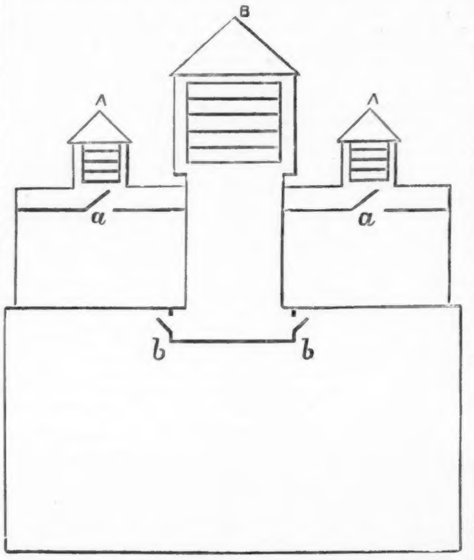
Our illustration shows a massive and powerful patent quadruple-geared duplex lathe, recently constructed for Messrs. Wm. Jessop and Sons, of Sheffield, by Messrs. Hulse and Co., Ordsal Works, Manchester. This lathe has been specially designed for dealing with marine crank shafts of the largest sizes, but is capable also of turning and boring other large steel castings and forgings up to 12ft. diameter and 30ft. in length. There are rests for four cutting tools, two operating at the front and two at the back of the lathe. These are respectively mounted upon four independent sliding carriages, each provided with swing frame, change-wheels, reversing gear, and rotating nut, in order that any one or more may be sliding while the others are surfacing at the same or various rates of traverse, and in the same or different directions, according to requirements. Two non-rotating steel guide screws firmly secured to the bearings at the end of each, and with swing bearings at intervals between, are placed one between each pair of the longitudinal box girders of the slide bed, and upon these the nuts underneath the carriages are revolved. Rotary motion for the feed traverse is transmitted to the carriages from the fast headstock through vertical and horizontal steel shafts and bevel gearing, while for traversing the carriages quickly by power along the bed the horizontal shafts are driven by strap pulleys direct. The changes from feeding to quick traversing are readily effected by clutches and levers. The fast headstock has a face-plate and chuck 10ft. diameter, cellular in form, externally geared, and fitted with cast steel jaws and screws. The gearing is double and quadruple, affording sixteen changes of speed uniformly graduated. The main spindle is of forged steel running in hard gun-metal steps, square in outline, and the back bearing has collars, propeller-like, for taking the end thrust. The changes from one gear to another are rapidly and easily effected.

The movable headstock spindle is traversed by a screw, with worm and wheel for forcing the centre into the work, and a hand-wheel operating direct on the screw gives quick adjustment. This headstock is traversed to any position along the bed by one or other of the sliding carriages, to which it may readily be coupled for the purpose. Two of the top rests have compound slides, and two are specially narrow for turning crank-pins and inside webs. One of each kind is interchangeable between the two front carriages, and one of each between the two back ones. The compound back rest has its vee inverted, in order to withstand a heavy "up" cut without vibration. As will be gathered from the foregoing description, there are no intermittent feeders. The large steel forgings and castings of the lathe, it may be added, are of Messrs. Jessop's special steel.

## AN IMPROVED SYSTEM OF VENTILATION.

We here illustrate by means of a small diagram a ventilating system which has been introduced by Mr. Albert Napper, of Guildford. It has been tried with success in a large hall, and we think any possible solution of the many mysteries in connection with ventilation cannot fail to be acceptable to engineers, particularly to those who are engaged on sanitary or architectural work.

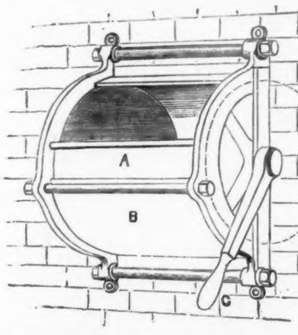
It will be seen from the accompanying diagram that a shaft B is placed in the centre of the ridge of the roof, and carried through the space between the roof and the ceiling into the room below. Under this shaft is an enclosed chamber fitted with hinged flaps—*b b*—one at each end, which automatically regulate the admission of air, care being taken that the flaps are not allowed to drop quite to the horizontal line, so that the air falling on to the floor of the chamber may be directed upwards and thus dispersed without a draught. This air, from its density, will readily fall to the floor and force the rarefied and foul air up to the ceiling, through which it will pass by means of small openings into the loft above.



To force the rarefied air out of the loft against the pressure of the dense external atmosphere, the same atmospheric pressure is brought to bear upon it from above. This is effected by placing two small shafts—A A—one on each side of the central shaft, on the ridge, and opening directly, but for the intervention of the adjustable flaps *a a*, on to the heated air in the loft. Thus a free supply of cold air is obtained, forcing, Mr. Napper says, the foul air up from the hall into the loft, where it is met by the same atmospheric resistance above, thus placing the foul air between two currents of cold air. It seems that the cold air has an immediate action in reducing the bulk of the warm air in the loft, and thus produces a partial vacuum which demands air from below. This does not appear to be sufficient to account for the cooling of the large body of air concerned, and the result is probably in a measure due to the upper strata of the warm air, in coming into contact with the cold, gaining so much in density that there is but little resistance left to its escape by one or both of the smaller shafts. Whatever the physical action may be, the desired end is obtained, viz., a continuous supply of fresh air into the hall, and that without draught. The mode of operation thus set forth is as described to us by Mr. Napper, but with regard to the functions of the outlets A A it may be said that their action in any way except as outlets is not quite obvious.

## A NOVEL DUST TRAP.

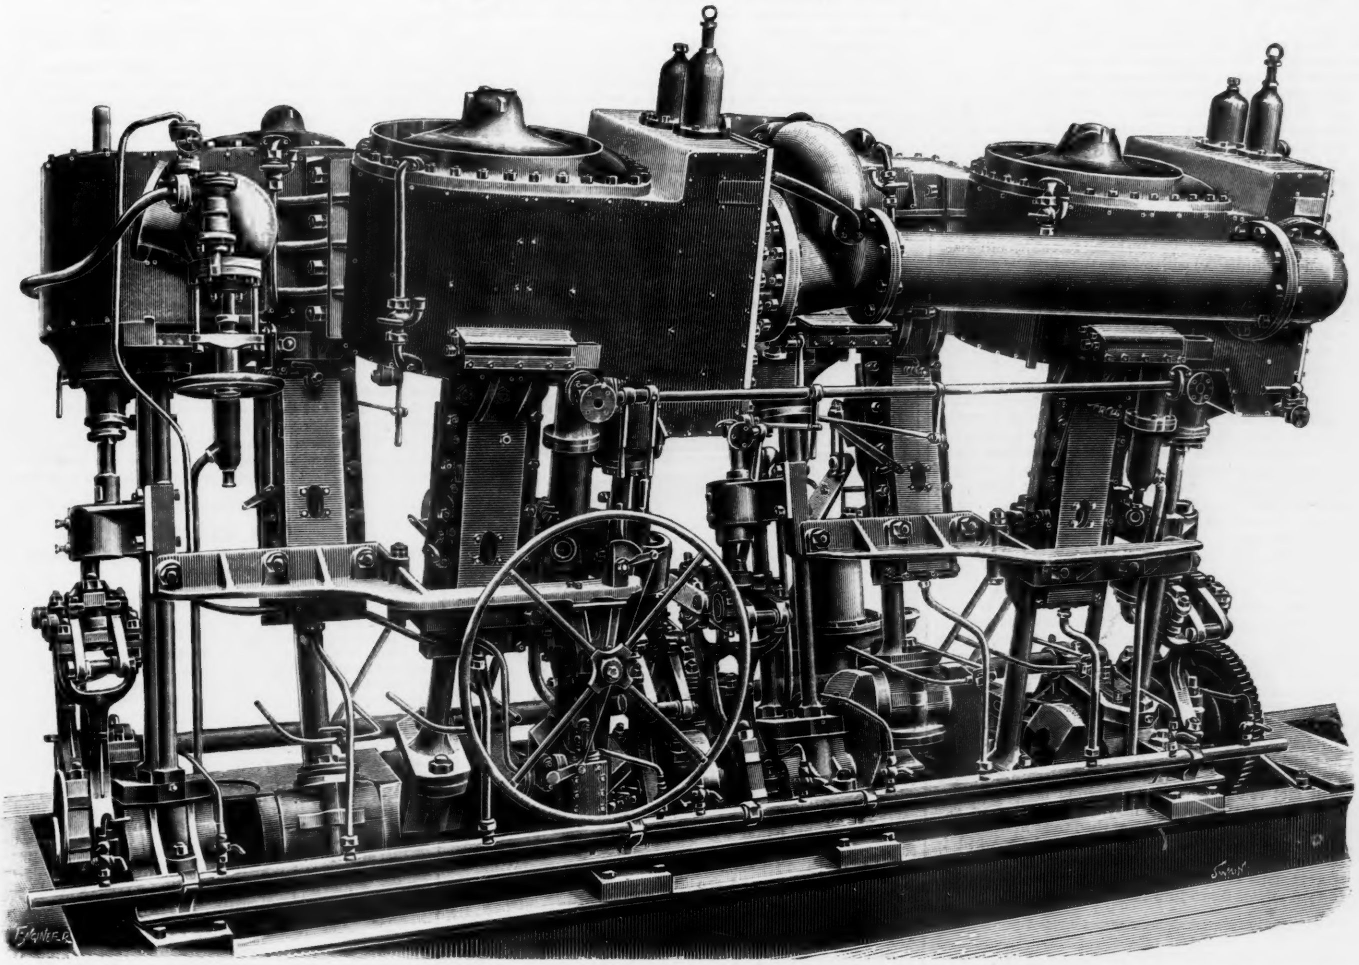
The dust trap here illustrated is intended to take the place of the ordinary shoot door. It appears to have so many advantages over the ordinary hopper that we think it is entitled to some notice. It is made by Messrs. Hall, Beddall and Co., of Waterloo-road, S.E., and consists of a drum-like hopper A working in a cylindrical casing B; a lever C is provided by means of which the hopper is actuated. When the trap is opened, dust and refuse can be safely put in, and then, by an upward movement of the lever C, the hopper is carried round and emptied down the shoot on the other side of the wall, the orifice being closed simultaneously with the revolving of the hopper. It is claimed that this perfect closing of the trap prevents any inroad of vitiated air from the shoot. The hopper revolves in dust-proof bearings to obviate clogging.



The quantity of petroleum used for firing the main boiler plant at the World's Columbian Exposition, Chicago, amounted to upwards of 31,000 tons, and the work done is stated to have totalled 32,316,000 horse-power hours. This makes the consumption of oil about 2·1 lb. per horse-power hour.

# ENGINES OF H.M.S. DARING AND DECOY

MESSRS. J. I. THORNYCROFT AND CO., CHISWICK, ENGINEERS

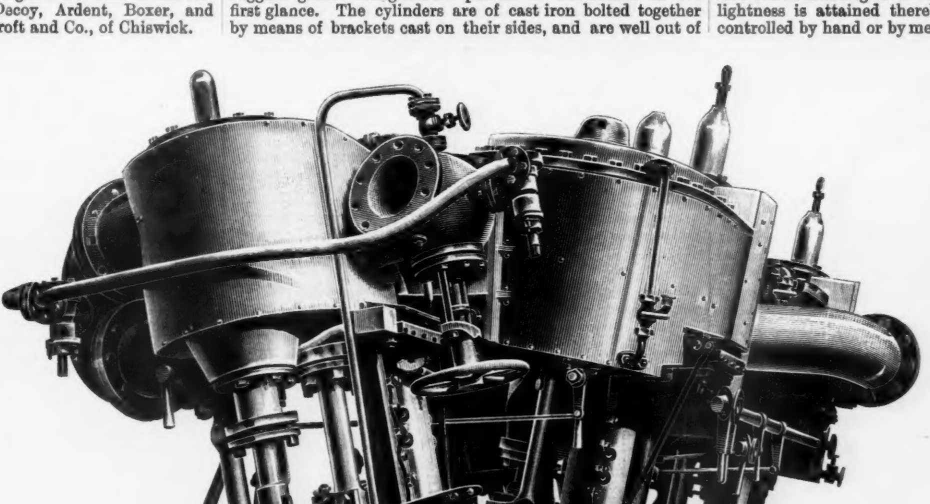


## ENGINES OF H.M.S. DARING AND DECOY.

We give above illustrations of engines as fitted in the torpedo boat Destroyers Daring, Decoy, Ardent, Boxer, and Bruiser, by Messrs. J. I. Thornycroft and Co., of Chiswick.

The principal feature in their design is the inclination of the engines, which are four in number — high, medium, and two low-pressure— overhanging alternately to port and starboard; the low-pressure engines are the aftermost. The centres of effort of each couple are not quite opposite one another—the deviation being that due to the obliquity of the engines with respect to one another, so that when one piston is at the top of its stroke the other is at the bottom. The foremost couple of course give twice the power given by the after couple, and exert their turning moment on the crank shaft at right angles to that of latter. This system has been specially introduced by Mr. Thornycroft in order to obviate vibration, and we understand that the Daring on her trials was remarkably free from this trouble. We may here remind our readers that her record speed against the tide was 29·268 knots.

The diameters of the cylinders are as follows:— High-pressure, 19in.; medium pressure, 27in.; and two low-pressure of 27in., with 16in. stroke. The condensers, two in number for each boat, are not shown in the engravings. Each has a cooling surface of 2100 square feet, the air pumps, one for each condenser, having buckets 16¾in. in diameter, with a stroke of 5½in. The crank shaft is of steel, 6¾in. diameter at journals and 7½in. diameter at pins, constructed by the Dennistown Forge Company, of Dumbarton. The connecting-rods are hollow, and also of steel—as are, in fact, all the rods, there being scarcely any wrought iron about the engine at all. The valve motion is adjustable in every part, which is a most valuable property in fast running engines like these. The shortness of the excentric rods is rather striking in comparison with the length of the valve spindles, but this is rendered necessary by the position of the weigh-shaft, which is actuated by an all-round gear, and situated conveniently low down at the back of the engines. Altogether the parts are unusually accessible, and suggest great strength and powers of endurance at the first glance. The cylinders are of cast iron bolted together by means of brackets cast on their sides, and are well out of one another's way, so that the interior of the valve chests can be easily examined and attended to—more easily, in fact, than they have been hitherto in torpedo boats of the Destroyer class.



ENGINES, H.M.S. DECOY, END VIEW, LOOKING AFT

The columns supporting the cylinders are continuations of the main bearing bolts, but, as will be seen, they do not interfere with the lifting of the main bearing caps, and additional lightness is attained thereby. The all-round gear can be controlled by hand or by means of a small steam engine. The exhaust takes place through the backs of the slide valves through the balance rings, as plainly shown in the side elevation.

The Daring and Decoy are 185ft. long, by 19ft. beam, with a draught of 7ft. The three other vessels already named slightly differ from these two in size, but the machinery is the same in all five. The Thornycroft boilers employed are of the pattern described and illustrated in page 238 of our issue of the 23rd of last March.

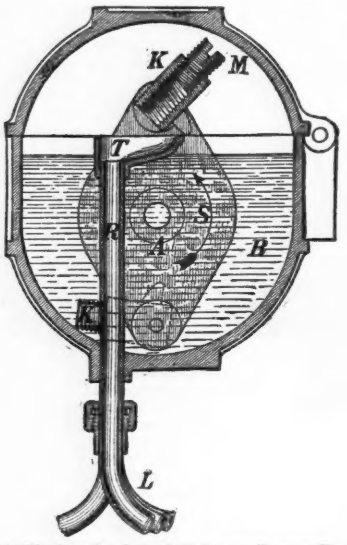
## ELEVATOR AND LIFT MACHINERY.

We can, as yet, find nothing in the shape of tall structures comparable with the lofty buildings of New York and Chicago, but recent buildings both in London and provincial towns indicate rapid advance in this direction. However regrettable from an artistic point of view such a tendency may be, tall buildings are certain to increase both in number and in height in all localities where ground is exorbitantly high in price. Such buildings have created a large demand for fast-running passenger elevators and the supply of these, together with the machinery required for operating them, already forms quite a considerable branch of the engineering trade. Apart from the actual hoisting apparatus, the supplying of such accessories as steam and gas engines, electric motors, hydraulic pumps and accumulators, &c., is generally open to the trade at large, usually falling to the share of local firms. In cities where low and high-pressure water, gas, and electric current supplies are available, a very wide choice is presented in regard to the methods to be adopted in running elevators in particular cases. Probably the simplest plan, consistent with the requirements of smooth running and absolute control, lies in the employment of a cylinder of considerable length, using gravitation water to press down a piston with rod attached to overhead pulley and wire rope gear. This method, though simple and inexpensive as to first cost, involves the loss of a cylinder-full of water for every run, and at the meter price usually charged by corporations the water bill mounts to a formidable sum when the elevator is in frequent use. An obvious step towards economy is to employ a pumping engine to force water to a tank placed at a sufficient elevation to give the required pressure. By this means the same water can be used over and over again, and the meter charge is done away with. A gas engine is usually employed to drive the pump, but the gas bill for the same amount of work is usually found to be much less than that for water, and in spite of the extra cost for plant and attendance, many such installations are working in a highly satisfactory manner, with the additional advantage that in case of temporary derangement of the pumping apparatus the use of gravitation water can be easily resorted to.

Gas engines are also employed to a limited extent for high-pressure hydraulic installations, water being forced by a suitable pump into an accumulator, which feeds the elevator cylinder as required. If the gearing is arranged to throw the driving belt of the engine on to a loose pulley when the accumulator is full, allowing the engine to run light till a further demand for water is created, the arrangement works with considerable economy as far as the gas bill is concerned, but the first cost and complexity of the plan are against its adoption. Electro-motors are also used to some extent for operating elevators through the intermediacy of accumulators, the current being automatically switched off when the need for pumping ceases. The comparative cost of running such installations depends principally, of course, upon the price paid for motive force. Recently in a locality where the electric current is charged at the rate of 7d. per unit, and gas at 2s. 6d. per 1000ft., an electro-motor of the Brush type driving pumps against 700 lb. accumulator pressure was temporarily replaced by a gas engine of about 8 actual horse-power. The engine worked constantly for ten and a-half hours per day against a full load, no fast-and-loose pulley arrangement being provided. After a month's working, the cost of the gas burnt was found to be practically the same as that of the electric current used during an equal length of time. This tells in favour of the gas engine in this particular instance, as the electro-motor controlled by an automatic shunting device was in motion little more than half the number of hours run by the gas motor. But an electro-motor may be admirable where a gas engine would be quite out of place, and again the motor is liable to be thrown out when high-pressure water is available, even though the cost of power, per unit of energy, be considerably greater. The electric current is also used to a very considerable extent for driving elevators directly by means of motors operating the winching drums, and, of course, in such cases the current may be generated *in situ* by steam or gas engines, derived from the street mains where a public supply is available. Elevators may be worked in many different ways, and there is great scope for ingenuity in the arrangement of their operating machinery—practice not having yet settled down into hard-and-fast lines.

## NEW LUBRICATOR FOR BEARINGS.

We here give an illustration of a "Multiple" lubricator, for which is claimed, among other advantages, a great saving of oil. The engraving shows a section in which B is the oil box, through the bottom of which is placed a number of tubes R. These tubes are provided with funnels T, and connected outside with tubes to the different bearings.



The oil is lifted to the funnel T by small cups K, which are placed on the revolving plates S. These plates are fastened to the axle A, which passes through the oil box, and is connected to a ratchet-wheel and lever to any moving part of the engine. In the course of revolving the cups empty the oil into the various oil pipes, and the quantity each cup supplies can be regulated by the screw M, which forms the bottom of the cup. Each bearing can therefore be provided with the necessary quantity of oil required. Much smaller feed pipes than those ordinarily employed can be used. The makers are Messrs. William Reid and Co., of Fenchurch-street, E.C.

Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Fleet engineer: W. M. Teak, to the Pembroke, additional. Staff engineers: John S. Watch, to the Walleroo; G. Parsons, to the Apollo; and Richard G. Willby, to the Orlando. Chief engineers: Arthur W. Turner, to the Sharpshooter; and Thos. C. C. Hughes, to the Speedwell. Engineers: F. G. Jacobs, to the Goldfinch; Septimus Ham, to the Dart; W. P. Chapman, to the Rapid; J. M. Simpson, to the Lizard; Albert E. Cox, to the Orlando; Edgar H. Ellis, to the Vivid, additional; Howard Bone, to the Sharpshooter; Thomas H. B. Bishop, to the Pembroke, and Henry T. Winney, to the Victory, both additional. Assistant engineers: John S. Hare and John Murphy, to the Orlando; Reginald W. Skelton, to the Centurion; and A. Whitmarsh, to the Vivid.

## A WOOD-CARVING MACHINE.

A new wood-carving machine, called the "Eclipse," invented by Messrs. Ryland and Bird, may be seen at work by those interested at The Mart, Station-road, Brixton, London. Fig. 1 gives a general idea of its construction, and Fig. 2 goes more into details.

A peculiarity of this machine is the elasticity of the motions which can be given to the cutting tool, combined with sufficient rigidity. The tracing pointer and carving tool are mounted on the front portion of a rectangular frame, extending over the machine table; this frame is mounted so that it will rock freely in its bearings; it can be moved in a line parallel to the front of the machine, and to and from the front and back of the machine table.

The back member of the tool frame is in the form of a shaft, on which are freely mounted one or more pairs of guide pulleys for the cutter driving band or bands. In slots or guides at the lower parts of the machine standards is mounted a countershaft, on which are loosely mounted one or more pairs of guide pulleys, and said countershaft is weighted or acted upon by springs to give it a normally downward tendency. The machine frame is fitted with a driving shaft carrying a long drum, and said driving shaft may be driven by a treadle or by power acting upon a driving pulley fixed thereon.

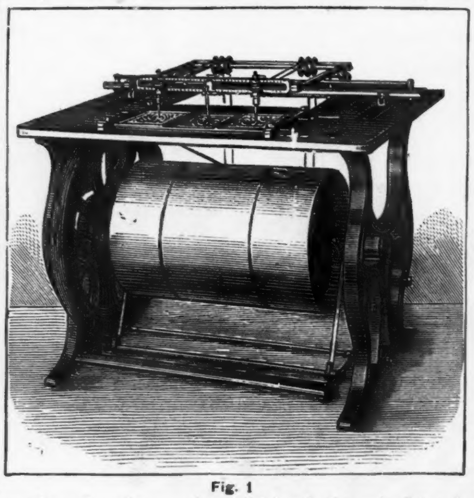


Fig. 1

A driving band for each cutter or carving or engraving tool is passed partly around the drum, then partly around the several pairs of guide pulleys above described, and partly around the driving pulley of the carving or engraving tool. The guide pulleys are capable of sliding along their carrying shafts, and the cutter driving band or bands is, or are, capable of travelling along the long drum. By the above construction of parts the tracing point and the carving or engraving cutter or cutters are capable of being moved in any direction over the pattern, and work without in any way affecting the driving of the cutter or cutters.

What with the guide pulleys sliding along their carrying shaft, and the driving bands of the cutters sliding wherever the tension draws them upon the long drum, and what with like freedom of motion of several other parts, the working parts of the machine seems as flexible as india-rubber, yet are sufficiently rigid. The machine will cut in any direction, and will undercut to a considerable extent. A boy can work it; indeed has been working it for a few months past. The few of these machines at present made are worked by a treadle. Power carving machines are, however, about to be constructed, also a miniature machine for amateurs. The amount of give-and-take with this machine, because of its tension gearing, prevents the heating of the bearings of the tools, which are necessarily driven at high velocities, and the length of wood which may be worked with it is unlimited. The machine seems to be able to carve anything, busts included. Various specimens of work done by it are on view, and more can be executed under the eyes of the spectator. The ligaments used with this machine are not leather bands but cylindrical lengths of catgut, treated occasionally with pure linseed oil gold-size, then allowed plenty of time to dry. The machine is patented in many countries.

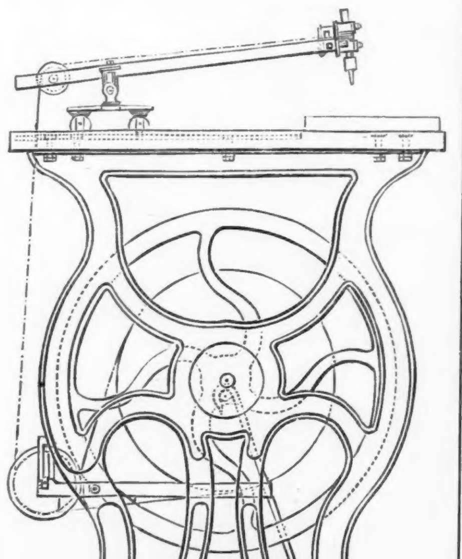

Fig. 2

## GREAT NORTHERN RAILWAY—RECONSTRUCTION OF A BRIDGE OVER THE DON.

Among the many bridges that the Great Northern Railway Company has found it necessary to reconstruct, is one directly north of the station at Doncaster, and over the Don Navigation. As in all cases of reconstruction, the real difficulty to be overcome was the removal of the old and fixing the new structure without interfering with the traffic of the seven companies using the bridge. Including shunting trains, upwards of 200 pass over the bridge every week day. On Sundays the traffic is considerably lighter, consequently the change had to be made on that day, the time fixed upon being between the departure of a train leaving Doncaster at 9.15 a.m. and the arrival of one at 10.50 a.m., giving one hour and thirty-five minutes for the operation.

We give this week the first of several illustrations of this work, which has been most satisfactorily carried out by Messrs. A. Handyside and Co., of Derby. Fig. 1 shows the old bridge moved out, and the new bridge fixed. Fig. 2 shows the girder unloaded, and ready for being moved out. Fig. 3 is a general view of the main girder, resting upon a steel trolley. Fig. 4 is the girder unloaded and ready to be moved out. It is identical with Fig. 2, taken from another point of view. The operation was very simple in principle, the old girder was moved out while the new one was moved in. The details of the method employed we shall give next week.

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### LOCOMOTIVE ENGINE BOWS.

Sir,—I see it stated in the newspapers that forty locomotives have been built by the Paris, Lyons, and Mediterranean Railway, the fronts of which have been designed in the form of "bows," similar to a ship, in order to cleave the air and reduce resistance at high speeds, and that a saving of 10 per cent. of the coal consumption, speed for speed, is said to have been effected.

Six years ago I made some theoretical investigations of this subject, and arrived at the conclusion that it was certainly worth while adopting such an arrangement in express trains. I laid my views before several of the leading locomotive superintendents, with the object of inducing them to undertake the experiment, but the idea met with a number of objections, and I did not attempt to follow it out. Difficulties in the way of getting at the engine and of shunting were suggested, and it was thought that the head resistance was so insignificant compared with the skin friction and the effect of a side wind that it might be neglected. It seems obvious, however, that the effect of a directly opposed resistance due to the motion of air at a speed of sixty miles per hour—which would be nearly 20 lb. per square foot—is at least comparable to the frictional resistance, both between air and train and wheels and rail, produced by a side wind of similar force, and even that is of comparatively seldom occurrence.

I would point out, however, that it is probably of equal importance to have the tail of the train formed in the same way, so that the air may be replaced as gradually and gently as it is displaced in front. This is not at first sight so obvious, but it is undoubtedly true in the case of a ship moving in water, where the energy of the particles, which would otherwise be entirely dissipated in fluid friction, produces a forward pressure on the vessel. It is not said whether this is being done on the French railway referred to, but it is probably not, and this may account for the difference between the saving of coal effected and the result estimated by calculation, which comes out considerably higher.

Now that a foreign railway has adopted this improvement, it may be hoped that English engineers will be enlightened enough to follow it up, more especially as we have a larger proportion of high-speed trains in this country than in any other, and it is to these in the first instance that it should be applied.

Stephen Smith.

3, Howard-place, Edinburgh, August 24th.

[Experiments carried out many years ago proved that with speeds up to forty miles an hour not the smallest advantage was gained by fitting wedges or bows to the ends of trains.—Ed. E.]

### ENGINEERS IN AUSTRALIA.

Sir,—I consider it my duty through your columns to warn civil engineers against coming to Australia in the hope of securing engagements. The total stoppage of public works, and the almost bankrupt condition of the colonies, have thrown great numbers out of employment, over three hundred engineers, surveyors, and draughtsmen having been dismissed from the Victorian Railway Department alone, while the other departments have been similarly retrenched.

Even when an appointment is obtained the remuneration is so low that only those who are in dire necessity would accept it. For instance, I enclose an advertisement from a colonial newspaper calling for applications from qualified persons to fill the combined offices of engineer, secretary, rate-collector and valuer to a Shire, and engineer, secretary, rate-collector and caretaker to a Waterworks Trust at a total salary for the eight offices of £150 per annum, out of which the successful candidate has to keep a horse and pay his own expenses. The applicants included one M.I.C.E., also one M.C.E.—Master of Civil Engineering—and member of the senate of Melbourne University. As a road labourer with his horse and cart receives ten shillings a day, this will show how miserably professional men are paid.

Then, again, there is a sort of boycott against the employment of "imported" men, the *sine quâ non* for advancement being what is called "colonial experience." This is a term which might be explained as ignorance of the first principles of engineering science, together with a capacity for drinking bad whisky and a facility for using bad language.

I have met men who have come out here only to be disappointed, and I hope this letter may prevent a recurrence of the same. I enclose my card, and shall be pleased to afford any information I can supply about the Australian colonies to your readers.

Melbourne, Victoria, July 2nd. Britisher.

### THE FORBAN.

Sir,—With reference to a paragraph contained in your last issue, will you allow us to state that the Forban is not yet in its experimental stage, as she will be launched only at the beginning of 1895. Augustin Normand and Co.

Havre, August 27th.

### ENTROPY.

Sir,—In my letter of August 17th, I stated a question with regard to the name entropy wrongly. Although the error is self-evident, I shall feel obliged if you will allow me to correct it. The question occurs in the last paragraph. After the word "expansion," and before the words, "in order," the words "divided by the standard absolute temperature" should be inserted.

August 29th. William Donaldson.

## RAILWAY MATTERS.

It is stated that a strategic narrow gauge railway line is about to be begun between Brest and Conquet, a distance of 37 kilometres.

The Great Southern Railway of Spain continues to push on its line towards Granada, but as there are so many difficulties to contend with, the time for its completion is very doubtful.

The strengthening of the old bridges on the Madras Railway is progressing satisfactorily. The substitution of stronger girders for the Thootha Bridge on the North-West Line is completed.

Negotiations are pending between the Russian Government and a well-known French company for the supply of a considerable quantity of rails required to complete the Trans-Siberian Railway.

According to the British Vice-Consul at Kieff, towards the end of 1893 the South-Western Railway, whose general offices are at Kieff, placed an order with the South Russian Dneiper Works for 8046 tons of steel rails at the price of £11 per ton.

The construction of the Trans-African Railway has progressed so rapidly that the line is now in full operation as far as the Lower Cazengo, a length of 160 miles, and the track of about 170 miles connecting it with the upper course of the same river will be opened for traffic in October next.

The construction of the railway between Saga and Tsukazaki about 45 miles from Nagasaki, Japan, was commenced last year. According to the British Consul at Nagasaki, the immediate approaches to that place present great engineering difficulties, and the Kiushiu Railway Company does not seem disposed to grapple with them nor to meet the expense.

The mineral district of Krivoi Rag in South Russia has received further attention from the Imperial Government, and a branch line of railway, running close alongside the mines and quarries, has recently been opened, thus greatly facilitating the transport of the various minerals raised from the workings, amounting in the case of iron ore to 800,000 tons a year.

A little book by Mr. P. J. Vinter on the Great Western Railway and its expresses, gives information as to the speeds attained and other details of the Great Western service. It is interesting to note that the daily mileage of its express trains to-day is 9000, against about 3000 in 1888. It is published by Hoyton and Cole, Plymouth.

According to the *Gazeta Handlowa*, of Warsaw, the projected railway from Warsaw to Ostrolenka is not to be a direct line between those two places, but is to join the Vistula line at Jablonna, where the communication with Warsaw will continue on the existing line. The permanent way has been constructed as far as Zagroby on the left bank of the river Narew, but no rails have yet been laid down. The works for the extension of the line to Ostrolenka are to be commenced in the autumn.

The New York Railroad Commissioners who were asked to act as judges in the prize competition of the Metropolitan Traction Company for a motive power system for street railways, which should be superior to the trolley system, have issued a statement giving the recent correspondence between them and the Metropolitan Traction Company relative to the withdrawal of the prize of £10,000. The Commissioners state that they regret exceedingly the unsatisfactory termination of the affair.

The scheme submitted to the Jura-Simplon Railway Company for making a tunnel through the Simplon has been approved in principle by the Swiss Federal Council, which will now submit it to the Italian Government. According to the terms of the contract the tunnel is to be finished in five and a-half years with a single line of rails, and is to be so constructed as to admit of its being eventually widened for a second line of rails. The cost of the first undertaking is 54,500,000f., while the second line will involve an additional expenditure of 15,000,000f.

The Linares Almeria Railway progresses, although somewhat slowly, owing to the delay of the Government in paying the subvention, but it is confidently stated that £720,000 is to be voted by Parliament to meet this subvention. During the past year the contractors have imported for the railway 73,736 pine sleepers, weighing 5080 tons; 1094 tons rails and accessories, 1564 tons bridge iron, 140 tons material for shops and stations, 436 tons wagons and wheels, 299 tons of iron for the station building, three locomotives and their tenders, 13,168 tons cement and hydraulic lime. It is expected that the line will be opened for traffic as far as Guadix by the end of the year.

According to a recent Foreign-office report, the short railway of 2¾ miles length, from Tafia to Pernik, was opened in the early summer of 1893, thus enabling the output of the coal mines at the latter place to reach Tafia at a much smaller cost for transport. Considerable difficulties were met with on this line, owing to repeated landslips, but these seem to have been overcome. Great satisfaction has been expressed by the Bulgarian authorities with that portion of the rails for this line which was purchased from British firms, both as to quality and cheapness, and it is to be hoped that a British firm will secure the contract for the new line from Tafia to Roman, a distance of 67·1 miles. The contract for the construction of this line, after a keen competition, fell to a Bulgarian Syndicate for £859,000. Other railway schemes were under discussion during the past year, notably one for the construction of a direct line from Tarambey, where the Bulgarian State line joins the Oriental Railway Company's line to Tambody, from whence the line to Bourgas is again in the hands of the Bulgarian Government. It is calculated that if such a line were constructed, the Bulgarian authorities, holding the communication between the port of Bourgas and the interior entirely in their own hands, would be able largely to reduce the freights now exacted by the Oriental Railway Company.

Not long ago some articles were published in the *Times* on the subject of light railways, giving a general account of the method in which the benefits of cheap railway transport had been extended to thinly-populated agricultural districts in foreign countries without the great expense of first construction and equipment that are involved in building such railways as our Board of Trade rules require. A correspondent, in writing recently and giving some particulars of a line of this character, which may be regarded as typical, and which has been at work for two years successfully, says:—"One great advantage of this narrow gauge and portable permanent way—an advantage which our British engineers have not, perhaps, considered—is the facility with which farmers and others can lay down a temporary siding or branch which can be moved about into any field or to any warehouse or barn where there may be a few train loads to pick up. With the line we are now considering this advantage has been largely realised." He further states that no stations were built further than an open shed with a small office to hold a weighing machine and to lock up parcels. Tickets to passengers are issued on the train by the conductor. Last year—the only complete year it has been in operation—it carried 27,235 passengers, and during the beetroot season, lasting two months, it carried over 15,000 tons of beetroot. The results were sufficient to show that in ordinary years the department will receive an income from the line. Indirectly, the population all benefit by the saving in cost of carriage and in the cost of keeping up the roads to a larger extent than they lose by the increase in rates or taxes to pay interest on the capital cost of the railway.

## NOTES AND MEMORANDA.

The Queen has approved of the new denominations of standards for electrical measurement.

Professor Campbell, of the Lick Observatory, has announced that the planet Mars presents no evidence of having an atmosphere.

An eminent German scientist, Professor Kohlrausch, has made experiments with the purest water which he could obtain, and finds that a column of 1in. has a resistance equal to a copper wire of the same cross-section passing twenty-five thousand times around the earth.

The amount of the world's supply of tin for the year 1893 is given officially in the annual report of Dr. D. T. Day. The total amount for the year was 67,237 tons, classed as follows:—English production, 8650; Straits' shipments to Europe and America, 38,874; Australia shipments to Europe and America, 5579; Banca sales in Holland, 5418, and Billeton sales in Java, 5211.

According to the June report of the Metropolitan Water Supply, the number of miles of streets containing water pipes constantly charged in each water company's district within the metropolis is as follows:—Chelsea, 85¼; East London, 185; Grand Junction, 135; Kent, 177½; Lambeth, 202; New River, 339; Southwark and Vauxhall, 160; West Middlesex, 133; total, 1416⅜ miles.

In the return of the gas testings for the week ending August 18th, W. T. Dibdin, F.C.S., enters as the highest mean illuminating power in standard candles that of the Blackfriars-road supply, from the South Metropolitan Gas Company, viz., 17·3, the lowest being those of the two Chelsea districts, supplied by the Gas Light and Coke Co., and the Old Ford district, supplied by the Commercial Gas Company, which were 16·1.

At a recent meeting of the Paris Academy of Sciences a paper was read on "Manganese Steel," by M. H. Le Chatelier. The anomalous results found previously by the author in studying the electric resistance of—13 per cent.—ferro-manganese are explained by the formation of two allotropic varieties of the metal. The temperature of transformation is 740 deg., that temperature at which soft iron passes from the magnetic to the non-magnetic state.

In London 2378 births and 1284 deaths were registered last week. Allowing for increase of population, the births were 242, and the deaths 271, below the average numbers in the corresponding weeks of the last ten years. The annual death rate per 1000 from all causes, which had been 17·6, 17·4, and 17·1 in the preceding three weeks, further fell last week to 15·4. In Greater London 3215 births and 1671 deaths were registered, corresponding to annual rates of 28·2 and 14·7 per 1000 of the estimated population.

One of the little-known compounds of iodine is the iodomercurate of copper, $HgCu_2I_4$. It is prepared by adding solution of cupric sulphate to a boiling solution of Meyer's reagent; part of the iodine is liberated, and a black precipitate thrown down, which becomes bright scarlet on cooling. At temperatures of about 150 deg. Fah. this becomes black, and regains its colour on cooling. If painted on a bearing, it at once shows any heating long before it can do mischief. In engines, where there are many bearings, and some difficult of access, this should be useful. Marine engineers take notice.

The bind used in the recent experiments at a Cumberland colliery with a view of making coal briquettes without admixture of pitch or lime, is partly a waste product, the remainder costing on an average from 20s. to 28s. per ton, according to yield and demand. From 4½ per cent. to 5 per cent. of the bind is added to the coal, and a briquette is obtained which neither cracks or crumbles, but which burns freely in an ordinary fire or under steam boilers, either with or without forced draught, leaving no slag or clinker. The tenacity of the bind is stated to be such that it permits the moulding of briquettes 4in. by 2½in. by 1½in.

In the report on the condition of the Metropolitan water supply during the month of June we read that the water in the Thames was 7in. above the average summer level, and at its lowest point 5in. below that level. The total rainfall during the month at West Molesey was 1·92in. The average daily supply delivered from the Thames during the month was 108,945,415 gallons; from the Lea, 52,911,162 gallons; from springs and wells, 34,884,036 gallons; from ponds at Hampstead and Highgate, 170,590 gallons, the last being used for non-domestic purposes only. The daily total was therefore 196,911,203 gallons for a population estimated at 5,447,027, representing a daily consumption per head of 36·15 gallons for all purposes. The relative proportions of the supplies from the above various sources were as follows:—From the Thames, 55·33 per cent.; Lea, 26·87 per cent.; springs and wells, 17·72 per cent.; ponds, 0·08 per cent.

Some tests of centrifugal pumps under high lifts are described by Mr. Gerard Lavergne in a recent issue of the *Genie Civil*. The design of the pump was modified so that the discharge through the wheel casing is taken through a narrow orifice extending around the entire circumference of the casing. This orifice gradually widens outward to allow the water to arrive without shock in a spiral collector surrounding the pump and leading into the discharge pipe. The width of the orifice is such as to give the required flow at the velocity due to the head against the pump, with an allowance 0·6 for contraction. Diagrams are given of the efficiency of the pump in terms of the lift for deliveries varying from 1 to 5·4 gallons a second and lifts up to 164ft. The maximum mechanical efficiency of the pump was found to be but 58 per cent., and occurred only with the greatest flow, about 5·4 gallons. The maximum efficiency for any given rate of delivery occurred when the lift was between 50ft. and 60ft. Another pump was constructed after these trials, in which the form of the blades and of the casing was altered from that first adopted, and with this pump an efficiency of 65 per cent. was obtained with a discharge of 6·6 gallons under a head of 65·6ft. and an efficiency of 68 per cent. with a discharge of 7·8 gallons under a head of 32·8ft.

An open scale barometer, showing minute variations of pressure, is the invention of Mr. C. O. Bartrum, and is made by Mr. J. J. Hicks, of Hatton-garden. It consists, says the *Times*, of a tube between 4ft. and 5ft. long, terminating in a cistern. The lower half contains mercury, and the upper a light fluid which forms the manometric index. About its middle the tube is expanded into a bulb about 3in. long, in which the two fluids meet. It is plain that a rise of mercury in the bulb will cause a much greater rise of the light fluid in the narrower upper tube, the amount depending on the sectional area of the bulb as compared with that of the upper tube. If the diameters of the bulb and cistern be each 1·5in. and that of the upper tube 0·02in., then an increase of 1in. in pressure as shown by a mercurial barometer will appear on the scale as 8·2in., or in other words, the scale is more than eight times as open as that of an ordinary barometer. Small changes of pressure can therefore be read with ease. The liquid in the upper part is methyl salicylate, a substance with a specific gravity about one-twelfth that of mercury, and a very small vapour tension at ordinary temperatures. The last point is important, as on it depends the excellence of the vacuum, and, consequently, of the instrument, for which the maker claims great sensitiveness and accuracy of reading to 1·200th of an inch. It can be made with as open a scale as a glycerine barometer, which is five or six times as long, and is, moreover, liable to become inaccurate in course of time on account of the vacuum being impaired by the infiltration of air through the glycerine. From this defect Bartrum's instrument is said to be free.

## MISCELLANEA.

H.M.S. Assistance is for sale.

It is stated that the supports of the lighthouse on the Fastnet Rock are unsafe.

During the past financial year 8000 miles of wire were added to the Indian telegraph system.

A technical meeting of the Photographic Society on limelight apparatus was held on the 28th inst.

The two new Russian ironclads, the Sevastopol and St. Peter and St. Paul, will be launched at St. Petersburg next October.

The new Russian battleship Rostislav, building at Nicolaieff, is to be a slightly modified Sissoi Veliki, of about 9000 tons displacement.

A printing exhibition will be held in Russia in 1895. If possible, there will also be a convention of persons connected with the craft and lectures given.

A stream of water has broken into the workings of Eppleton Colliery, one of the group owned by the Hetton Coal Company, and stopped operations.

A vessel of 1500 tons has been launched as close to Paris as St. Denis-sur-Seine. She is a steel sailing vessel named the Geneviève for the Société Navale d'Armament.

The launch of the new cruiser Calabria, which is being built in the royal dockyards of Spezia for the Italian Navy, has been provisionally fixed for the 20th of September.

There has been received at the Frankfort Arsenal, U.S., from Germany more than 3000 lb. of smokeless powder, which will be sent to Sandy Hook for test in the big guns.

The floating pontoon dock, built on the Tyne to the order of the Manchester Ship Canal Pontoon and Dry Dock Company, is now in position at Mode Wheel. The pontoon dock is 270ft. long by 63ft. wide.

The Admiralty have withdrawn the paid-off Indian troopships Euphrates and Serapis from the list of ships for sale, and have called for an estimate for new boilers and engines. The cost for each ship is estimated at £42,000.

We hear that the construction of the telegraph line between Burmah and China is being proceeded with. The course of the line will be from the Nampaung Fort, situated to the north-east of Bhamo, to Momein, *viâ* Manwieng, a distance of about 190 miles.

Mr. J. C. R. Okes, of 39, Queen Victoria-street, E.C., formerly associated with the late British Gas Engine Company, has been appointed sole representative in London and Southern Counties for the National Gas Engine Company, which has extensive works at Ashton-under-Lyne.

The new torpedo gunboat Harrier, off Plymouth, on Tuesday underwent a successful eight-hours steam trial. Her engines, with natural draught, developed 2696 horse-power, or nearly 200 beyond the guarantee, and her speed was 18 knots an hour, against 16·9 and 17·1 attained by her sister vessels Halcyon and Hazard.

Six schemes have been put forward in the Paris Chamber of Deputies for establishing a communication between England and France, which are as follows:—(1) A tunnel under the Channel. (2) A bridge over the Channel. (3) A transmarine tunnel. (4) A tubular railway. (5) A mixed passage. (6) A steam-ferry carrying a train.

For the convenience of travellers to the Continent, a special arrangement has come into force between the South-Eastern Railway Company and the International Sleeping Car and European Express Trains Company, by which a new special inquiry and ticket-office has been opened at the entry to the continental departure platform at Charing-cross station.

The contract for the extension of the Union Dock at West Hartlepool for the North-Eastern Railway Company has been secured by Mr. T. D. Ridley, of Middlesbrough, who completed the extension of the same company's Middlesbrough Dock. The area which the extension will cover is at present used as a timber dock, and this will be converted into a deep water dock.

The blocks used in the mahogany pavements in Paris are of real Brazilian mahogany of peculiar fine texture and colour. This wood is much more expensive than that ordinarily used for the same purpose. The actual cost of the new road will be fifty francs per square yard. It is an experiment at the best, the hope being that the durability will compensate for the outlay. The street in question is the Rue Lafayette.

A small steel cruiser of exceptional speed and radius of action is to be laid down at Brest. She is to do 23 knots at her forced draught trials, and 20 knots for four-and-twenty consecutive hours. The armament will consist of ten 3·9in. 28-pounder quick-firing and twelve 1·85in. 3-pounder quick-firing guns. There will be merely pole masts without military tops. In order to keep the vessel always at the same draught of water, arrangements are to be made whereby in proportion as her coal and provisions are exhausted water will be admitted to certain compartments.

The Nobel Company have given notice of appeal to the House of Lords against the judgment in the recent Cordite case pronounced by Mr. Justice Romer and unanimously affirmed by the Judges of the Appeal Court. Mr. Maxim is also desirous of fighting a claim for infringement of one of his patents for the production of smokeless powder. He has asked and obtained permission to proceed in the same manner as the Nobel Company, *i.e.*, by way of what is called a "friendly action," in which Dr. Anderson, on behalf of the Government, will be the defendant.

Staff-Engineer New, of H.M.S. Barfleur, seems to like his little joke. In an interview with a representative of the *Pall Mall Gazette*, headed, in the issue of August 17th of that organ as "Six Hundred Water-tight Doors," we abstract some information of a decidedly "new" description. For example, we first read that all the machinery in the ship is "in duplicate;" also that reservoirs for compressed air "come in handy" when there are torpedoes, "these gigantic horrors," to fire. A stoker's lot, we read further, is not so bad as a policeman's. What a pity it seems that this interviewer was unable to proceed with the ship on a forced draught run. He might then have thought otherwise. It is interesting also to read of the strength of the helmsman who with one finger is able to move the steering-wheel. But what are all these details when we learn that the horse-power of the Barfleur is 13,160 tons? "The engine-rooms are models of completeness," the article goes on; "in the first which I visited is an engine for circulating water through the main condenser." Wonderful! By the way, it would be interesting to know how the other condenser gets on. Perhaps it does not condense at all. The auxiliary condenser, on the other hand, blossoms forth into an importance hitherto unrecognised. It clearly discharges a greater function in the Barfleur than it has ever been known to do before single-handed. Altogether the machinery is of a most curious description, for we read that "the engine which drives the starboard screw does its duty without making the slightest noise." The stokeholds are described as lofty and roomy, light and airy. The luxury, too, of the stokers' bathroom—a wonderful ship! We must avail ourselves of the first opportunity that occurs of inspecting this unique battleship.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

D. B. (Exeter).—*You can send us on the model if you think proper, but we cannot accept any responsibility about it.*

K. and Co. (Antwerp).—*We have already illustrated the Laval turbine applied to drive a dynamo in our impression for October 20th, 1893. If you have any new features to describe we shall be glad to hear further from you.*

A. M. B. (Quebec).—*You cannot do as well in the kind of practical technical education here as, according to your description, you can at the Pratt Institute. The "Construction of Modern Locomotive" articles are completed. Sectional drawings mentioned not given. Some other points on American locomotives in* The Engineer, *August 17th.*

### OSCILLATING v. INCLINED COMPOUND PADDLE ENGINES.

*(To the Editor of The Engineer.)*

Sir,—I shall be very much obliged to any of your readers for an expression of opinion based on experience of the relative merits of these two systems. Engines of both classes are used in the fast traffic between this country and the Continent. The Zeeland S.S. Company adheres to the oscillating system, while the Belgian Government boats use inclined engines. Both types have been built on the Clyde. Which is the better?

London, August 29th. Voyager.

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)* .. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. .. £1 0s. 3d.
*Yearly* .. .. .. .. .. .. .. .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

### MEETINGS NEXT WEEK.

London Association of Foremen Engineers and Draughtsmen.—Saturday, September 1st, at Cannon-street Hotel, at 7 p.m. Monthly Meeting. Paper: "A Visit to the Scotch Leval Shale Mines," by James J. Pike.

The Federated Institution of Mining Engineers.—Wednesday and Thursday, September 5th and 6th, at Newcastle-on-Tyne. Annual general meeting. Numerous excursions will take place.

### DEATHS.

On the 21st inst., at his residence, Riverbank, Sunbury-on-Thames, Henry Faija, M.I.C.E., of Old Queen-street, Westminster, and Harcourt-terrace, South Kensington, aged 49 years.

On July 30th, suddenly, at Johannesburg, South Africa, James French, Assoc. Mem. I.C.E., age 48 years, second son of William French, surveyor, late of Delahay-street, Westminster.

# THE ENGINEER.

*AUGUST* 31, 1894.

## THE PART OF COAL DUST IN MINE EXPLOSIONS.

While the Home-office is apparently hesitating to resume and continue on its own account the experiments commenced by Mr. Hall in Lancashire, with regard to the explosive qualities of coal dust in mines, mining engineers and colliery managers in South Wales are making efforts to solve the problem for themselves by tests which are carried out on what may be called for the nonce the "voluntary principle." In the locality there is undoubtedly a great deal of dissatisfaction with the verdict of the coroner's inquest into the causes of the death of the victims of the Albion Colliery disaster. It is not surprising or unnatural that the finding should be regarded as inconclusive. What can be expected of an ordinary coroner's jury—and here were two juries and two coroners, because of the deaths falling in two jurisdictions—when questions of the greatest delicacy and complexity have to be determined? How can the most "highly respectable" body of jurors decide on matters when mining experts have had to confess that for their final opinion they are awaiting more positive evidence? It is only the gravity of the calamity which calls attention to the insufficiency and inefficiency of our present method of investigating its causes. If colliery explosions and terrible death-rolls were of as common occurrence as, say, railway accidents, the coroner would inevitably be supplemented or superseded by an engineering expert who would take all the scientific evidence he could get, and present to the Government a report which should at all events have the merit of being impartial and scientifically precise.

The South Wales mining engineers are even now in doubt as to the relative strength of the explosive powers of coal dust in different pits; in different measures in the same pit, and in different pits dipping to the same measures. The question may be said to depend very largely, if not mainly, on the relative moisture of the workings. But to put it in that way bears too much of the appearance of a platitude. If it were possible to discover a denomination for this standard, one would prefer to say that the question depended more particularly upon the power of absorption, the capacity of saturation, of the roadways and roof throughout the working places, from the downcast shaft right away to the "face." No coal mine is really dry; but there are many in which Welsh coal, and especially the subsidiary seams, run through strata which for long distances seem impervious to water; and on this difference between dryness and moisture of the atmosphere of a pit—it is to South Wales we are especially referring—rests the undetermined issue under which the coal dust is dangerously explosive whether as dangerously explosive as fire-damp, or more explosive intrinsically, because of its fiery gaseous particles, than four times the quantity or volume of the carburetted hydrogen which one looks to as an incident of all coal mining explorations.

Some of these "voluntary" experiments were begun early in the month at the Lower Duffryn Collieries in the Aberdare Valley, not far from the spot whence "in the '30's" the first steam coal was carried—in a portmanteau it is reported—for examination on the London market. The coal measures worked there are not identical with those of the Albion seams, but they bear many points of resemblance in the hardness of sections of the coal and the flocculence and volatility of the dust. The point here was to test which was the safest class of explosive to use in connection with the coal dust of the 2ft. 9in. and 4ft. seams of these Lower Duffryn Collieries—dust taken from the "face" of the workings, as well as from the roadways. The first shot was of gunpowder, $1\frac{1}{2}$ lb., covered with coal dust from the 2ft. 9in. headings and roads. This caused a large flame, and the odour of burning coal dust was distinct at ten yards distance. With no coal dust, and the same quantity of gunpowder, the second shot resulted in a very much smaller and clearer flame. Compressed powder was next tried, covered with coal dust from the 4ft. seam, and again there was a large flame and a distinct odour of burning coal dust. The pit screens yielded a quantity of very fine dust, which was exploded by a charge of 1 lb. of gunpowder and two balls of compressed powder. There was now a greater flame, and heat felt at a still greater distance. Then we came to dust taken from the face of the mine, and the results surprised many an old practical observer. A quantity of dust from the stalls in the 4ft. seam was charged with 1 lb. of gunpowder and two balls of compressed powder, and this brought out a greater volume of flame and intensity of heat than came from the old dust that had hung and clustered about the roadway and headings. From about this stage the interest of the story increases to mining engineers. To the same amount of the coal dust from the face a charge of $\frac{1}{2}$ lb. of roburite was applied, ignited by electricity. It caused a loud enough report, but there was no perceptible flame. From the face of the 4ft. seam dust was taken. The charge was $\frac{1}{2}$ lb. ammonite in one case, and the other 1 lb. compressed powder placed at short intervals. The ammonite was first exploded; the compressed powder within a few seconds. The ammonite caused no flame; the compressed powder exploded in a blaze that might have set a pit on fire. Under the same conditions $\frac{3}{4}$ lb. carbonite was used, and no flame was emitted. To the extent to which their value may be ultimately proved, these experiments would seem to show that of the two forms of explosives used where coal dust is in the atmosphere of a mine, gunpowder in any form provokes a dreadful retort—to put it only in that way—while the high explosives are, as far as our knowledge at present goes, if not innocuous, in every way to be preferred.

But notwithstanding these demonstrations, there was still a difficulty to overcome. The colliers required to be convinced not only that gunpowder was unsafe, but that ammonite or some other high explosive would equally serve the purpose of economically dislodging the coal—that is to say, without shattering it into fragments. It was therefore arranged in the following week that a series of object lessons should be given at the same colliery for the instruction of Mr. David Morgan, miners' agent, and a deputation of the workmen. Mr. Morgan and the colliers, it should be premised, were strongly prejudiced in favour of gunpowder as an agent they were thoroughly familiar with, as one easily handled, and as one, moreover, which they refused to regard as dangerous, when skilfully used. If this be borne in mind, the conclusions forced upon the workmen's minds by the experiments will be recognised as the more important. The colliers and their agent were, in fact, convinced against their will. Mr. David Morgan shall be left, for the most part, to tell the story in his own words. So far as blasting was concerned, it was found that carbonite was more serviceable than ammonite, inasmuch as it did not smash the coal to the same extent as the latter, though Mr. Morgan estimates that carbonite is, weight for weight, only 50 per cent. stronger than gunpowder, and not 100 per cent., as the manufacturers claim. Then came the question of the effect of the shots as potential causes of the ignition of fire-damp or coal dust. During the experiments, twenty-eight shots of high explosives were fired. "Although I and the men most carefully watched," Mr. Morgan says, "we failed to distinguish the slightest appearance of flame, thus leading us to the conclusion that both carbonite and ammonite are harmless in the matter of igniting coal dust." And next, for the comparison with gunpowder. "We placed some 150 lb. of perfectly dry coal dust on a sheet of iron, and under it a carbonite cartridge, which was ignited by electricity. This blew up the dust in large clouds in every direction; but none of it ignited, and we saw no trace of a flame. The same experiment was tried with ammonite, with the same result. We also tried the same thing with both loose gunpowder and with a cartridge of compressed gunpowder; in both cases flames were given off, and the dust ignited in all directions." Mr. Morgan, however, adds that he and the miners with him could not be sure that the whole of the dust was ignited, and accordingly they were still unconvinced that a blown-out shot, even if it ignited the dust close by, could cause a general explosion.

Mr. E. M. Hann, the general manager of the Powell Duffryn Collieries, and Mr. Gwilym Jones, the mine manager at Lower Duffryn, thereupon made provision for another experiment, under conditions by which the action of a blown-out shot could be reproduced. "First of all," says Mr. Morgan, "we placed about 2 cwt. of coal dust in front of a three-holed cannon, and put about $\frac{1}{3}$ lb. of loose powder in each hole, firing them simultaneously into the heap of dust. One of them made an effective flame of dust. The others merely blew the dust away to a slight extent. We repeated this experiment, and in this case neither of the shots ignited the dust. We then placed the same dust with some more on a metal sheet, and placed under it a carbonite cartridge. This cartridge was fired by electricity, and blew the dust in large clouds into the air, but with no trace of flame. At the moment the dust was thoroughly diffused a cartridge of compressed powder was fired into the dust cloud, and instantaneously it ignited, huge flames bursting in all directions." Mr. Morgan sums up finally with this deliverance:—"I unhesitatingly say that in the case of dry and dusty mines the use of gunpowder should be prohibited, and carbonite or some other flameless explosive used, unless by some means the gunpowder can be made flameless, which a manufacturer of compressed powder told me can be done. If we had only competent and skilled miners working in our mines, the dangers from a blown out shot would be very remote, for a skilled and experienced collier hardly ever has such a thing as a blown out shot. But unfortunately we have many unskilled colliers brought into the mines lately, who are unable to judge properly what work a shot can do."

On these points Mr. William Galloway, M. Inst. C.E., a well-known mining engineer and a Professor of the University College of Cardiff, makes a suggestion which is worthy of a wider circulation than that of the Cardiff journal in which his letter appeared. "It has occurred to me," he says, "that I might usefully offer to conduct some experiments with coal dust on a moderately large scale at a few of the principal mining centres of the district, so that those who have not seen coal dust in actual combustion might have an opportunity of doing so almost at their own doors. To this end I am prepared to devote the necessary time, and to provide the apparatus and assistance at my own cost." Why is Mr. Galloway so late in making this philanthropic offer? He asks the question himself, and answers it in his own way:—"Before or about the time of the appointment of the Royal Commission on Accidents in Mines, in the beginning of the year 1879, Mr. Archibald Hood, who has always been in the forefront of the coal dust question, proposed to me, and I agreed, that he should ask the Monmouthshire and South Wales Coalowners' Association to vote the sum of £1000 wherewith to build an apparatus at some central point in the coalfield by means of which the correctness of the coal dust theory, which was then comparatively new, might be demonstrated on an imposing scale. For several years previously—since 1875—I had been conducting experiments with coal dust in smaller apparatus. At that time, however, the matter fell into abeyance, for the Royal Commission referred to was instructed amongst other things to inquire into the influence of coal dust. It may seem strange after the prominence that has recently been given to Faraday's remarks about coal dust in 1845, that this was practically the first official notice taken of coal dust as a possibly important factor in colliery explosions."

His complaint continues that thirty-four years have elapsed, and nothing so far has been done by Act of Parliament or statutory rules of management, and scarcely a single tribute paid to the danger of coal dust as a cause of colliery explosions, until the Royal Commission on Coal Dust was appointed. "I suggested to that Commission," Mr. Galloway writes, "at a very early period of their existence, that the best means of convincing themselves and the public would be to erect an apparatus as large as a roadway in a mine, and to create explosions of coal dust within it, in the natural state, in the presence of all who could be induced to come and see. At the request of one of the members of the Commission, I went carefully into the matter, and recommended that an apparatus 7ft. in diameter and 200 yards long be built in a field near the Naval Collieries. I offered to give my services gratuitously, designed the apparatus, took tenders for its erection, and made arrangements with the owners of the colliery. The estimated cost was £5000. The matter was allowed to drop, ostensibly on account of its cost. The Commission has issued its report. But there appear to be still unbelievers. Hence my present offer, which I hope will meet with better success."

## THE ALIGNMENT OF TUNNELS.

There are probably very few railway engineers who, while serving their time in the field and in the office, under the "chief," were not made acquainted with, and expected to believe, the story of the two separate headings of a tunnel which were carried past one another instead of meeting, if not exactly, at any rate within that permissible limit of lateral deviation which is so gratifying to the resident engineer. Very few tunnels of dimensions worth recording, no matter how accurately they might have been aligned, or how truly they might have been driven, have had the good fortune to escape the wearing of this cap, whether it fitted them or not. Any one that had a curve in it was doomed. It is also stated—at least it was in a version given many years ago—that the fact of the "overlap" was ascertained by the circumstance of one of the gangs knocking off for dinner a minute or two before the other. The naturally acute hearing of the former, no doubt sharpened by appetite, enabled them to distinguish distinctly the sound of the jumpers, picks, shovels, hammers, and axes of their retreating comrades. In some remarks made by the President of the Institution of Civil Engineers in opening the discussion on a paper—"Tunnels on the Dore and Chinley Railway"—to which we shall presently more immediately refer, that gentleman cited a tunnel at Liverpool which rumour had impeached as the culprit, but it has been contended strongly that the honour, if any, belonged to a similar engineering work carrying the railway into Cork. Mr. Giles very truly remarked that "since that time better methods had been introduced to set out tunnels, and how necessary it was that in the setting out of preliminary work of that nature, the greatest possible accuracy should be observed."

The setting-out or alignment of a tunnel may be classed under three heads. First, the ranging or alignment above ground; secondly, that below, either in a heading or in the full section of the tunnel; and, thirdly, what may be termed the vertical alignment, or the transference of the surface-line to the subterranean one. Should the tunnel, similar to the longest two existing at Mont Cenis and Mont St. Gothard, be constructed without shafts, the vertical alignment is not required, as presumably the tunnel would be ranged from points observed directly from each extremity. In other words, the line of direction being given by the fixation of a couple of terminal points at any visible distance from the ends of the tunnel, the alignment may be obtained either by setting up the instrument, whether a plain transit or a theodolite, over the nearest point, sighting backwards, reversing and ranging forward, or by absolutely ranging the line backwards from the fixed points. It is extremely rare that the contours of the ground beneath which the tunnel is situated are sufficiently favourable to allow of one extremity being visible from the other; that is, to permit of the total length being ranged forward in either one direction or the other. The more general case is that in which, while the ends of the tunnel themselves are not sightable the one from the other, yet a summit level obtains from which as a common point, even if, as frequently occurs, the ends are not visible, points in the direction of the line of trace can be accurately determined, marked, and rendered available for the alignment of the face headings or driftways. The distance at which these points are located from the mouths of the tunnel will depend upon the physical features of the surface, but it is really a matter of little moment how far off they may be situated, so long as they are fairly within the range of the instrument employed. With this proviso, the farther off they are the better, as they admit of a more accurate and delicate adjustment by the cross wires of the telescope. In the Bletchingley tunnel these terminal points were situated at a distance of two miles from the extremities of the tunnel, and consisted of small, solidly built brick piers, painted black, with a white line in distinct relief on them. In setting out the Totley tunnel, a full and interesting description of which is given in the paper already mentioned, namely, "Tunnels on the Dore and Chinley Railway," by the late Percy Rickard, M. Inst. C.E., and read before the Institution of Civil Engineers, January 23rd of the present year, terminal points were also used. They were aligned by forward and backward sighting from a summit level, where an observatory had been built from which a view was obtained of a very extensive tract of the whole country. These two points were about 9000ft. and 7000ft. measured horizontally from the respective extremities of the tunnel. The distance of the same points from the summit observatory was over three miles, but by employing as a mark a board painted black, with a 3in. white line on it, fitted with a plummet and fixed by guy ropes, and placing behind the board at a few feet from it, so as to avoid shadow, a white calico screen, the mark could be distinctly distinguished so long as the sun was in front of the screen. These satisfactory results appear to agree with those generally obtained in a similar manner. It is now well established, both by past and present experience, that for long distances, white against black shows up best, and *vice versâ* for short distances. In the setting out of both the Totley and Cowburn tunnels, the latter being on the same line of railway, a black board, 2ft. by 1ft. 6in., faced with white cardboard, on which was drawn a broad arrow with varying widths of shaft, was levelled with a spirit level and supported from the back with light iron stays and used for short distances.

At each of these two terminal points described, as well as at six other stations, placed where marked changes in the contours of the ground occurred, observatories were built, for the location of the transit instrument used in aligning the tunnel. They were hollow, of brickwork in cement, capped with stone, with a large flat cast iron plate, having a hole 6in. wide in the centre let into the cap and run with cement, upon which the transit instrument rested. A brass scale of a width of 1½in., and divisions of inches and twentieths, was fixed across the central hole in the plate, and a plumb line from the centre of the instrument could be dropped through the hole to touch the side of the scale. It may be fairly questioned whether all these observatories are needed for a tunnel 6229 yards, or a trifle over 3½ miles in length. We do not go so far as to unreservedly endorse the views of some engineers, who maintain that—except in the case of very long tunnels—observatories are not required, and that strong permanent marks, over which a theodolite can be set up as often as required, will answer all the purposes of lining out and fixing the positions of the shafts. An inspection of the longitudinal section of the ground over the Totley tunnel, will point out that the observatories on the eastern side of the summit limit serve principally for checking the lines run from the summit and terminal stations. The plain transit instrument is generally used for aligning tunnels, as it is less complicated and has fewer adjustments than the theodolite; though a slight drawback may be found in the necessity for removing the cross-level every time the telescope is reversed, unless the operator is satisfied with one general levelling for each series of observations. It was suggested in the discussion that the compass might be employed, in the place of the transit; but such an idea is utterly inadmissible, and the very enunciation of it must sound very strangely in the ears of the modern engineer, who would as soon think of using a plane table or a box sextant. We are not aware of a single instance in which an instrument, so conspicuously inaccurate and imperfect as the compass, has been employed for the alignment of a railway tunnel worthy of the name. Even in mines, its ancient stronghold, it is being rapidly discarded; and, whenever practicable, the preference is given to the ordinary theodolite slightly modified in its arrangements and parts, to suit the exigencies of subterranean explorations. Without in the least underrating the value of the transit, we have no hesitation in stating from a long practice that a 6in. transit theodolite by a first-rate maker, in the hands of a skilful and experienced engineer, can be made to do anything and everything in connection with railway work, with an accuracy, precision, and fidelity which leave nothing to be desired.

As most tunnels are provided with shafts, the transference, or vertical alignment of the trace of the tunnel from above to below ground, is effected through them. The problem is to determine a vertical plane, perpendicular to the transverse axis of the tunnel, bounded by lines forming the surface and subterranean alignments, and connected at the points where the shafts occur by the vertical alignment, which may be regarded in the light of so many ordinates. The simplest case is obviously where the vertical plane passes through the longitudinal axis, that is where the shafts are ranged along the centre line of the tunnel. It should be mentioned that so far as the simple alignment is considered, the words tunnel and heading are used in the same sense. Instances have occurred in which the shafts have been run parallel to the centre line of the tunnel, and in the tunnel at Mont Cenis shafts—which more correctly might be termed drifts—were driven into the headings from the adjacent hillside. A similar example occurred in the Clifton tunnel, where a vertical alignment was set out from a station on the other side of the river Avon, through a horizontal gallery, ranged so as to intersect the centre line of the tunnel. The distance between any two consecutive ordinates in the vertical plane of alignment should be as great as possible, but unfortunately the diameters of shafts are generally of dimensions so limited as to restrict this length to about 8ft. or 9ft., and often to a less amount. Exceptions sometimes occur, as in the well-known Box tunnel, nearly two miles long, on the Great Western Railway, where some of the eleven principal shafts are 25ft. in diameter. A still more remarkable example may be found in the Kilsby tunnel, which has a main shaft 65ft. in diameter. Again, in the tunnel under the Hoosac Mountain, in Western Massachussetts, which has a total length of 4¾ miles, the shafts are not all of a cylindrical form. Some are in the shape of parallelograms, 13ft. by 6ft., others 14ft. by 8ft., and one is elliptical, with major and minor axes of 27ft. and 15ft. respectively, of which the former is in the direction of the trace. In effecting the practical transference of the centre line down the shafts, the old methods have been either abandoned, or partially employed under greatly ameliorated conditions. The apparatus employed for the Totley tunnel consisted of a winding drum, upon which the wire was wound, mounted upon an iron frame, with a ratchet and pawl to secure it in any position. The wire, which was weighted, passed over an adjusting screw, and was readily brought into line by turning the screw in either direction as required.

A few words regarding the "thirl," as the meeting of the separate headings is termed, will conclude our article. It might be supposed that the more numerous the shafts, and consequently the greater the number of ordinates in the vertical plane of alignment, the less would be the divergence at the points of junction of the different headings, or of the different independent lengths of the centre line, supposing the tunnel to have no headings, of which that at Sydenham furnishes an instance. Experience does not universally confirm this *primâ facie* rational and common-sense view of the subject, and a little consideration will discover the cause of the discrepancy. Every separate operation, or every repetition of the same operation, is not only a source of error, but undoubtedly a cause of actual error, even if of an amount too insignificant to be appreciable. Consequently, every transference of the centre line is attended with some slight error, which, in the event of the position of any particular shaft not being sightable from either the summit or terminal stations, and therefore requiring to be fixed by ranging from a previously determined shaft, might become cumulative. In the one case, the accuracy of the underground alignment depends upon that of a number of independent short lines, which may or may not have been set out from the same fixed points. On the other hand, the centre line of the shaftless tunnel underground is ranged from each end from two unalterable terminal stations. The total deviation of the headings in the Totley tunnel was 4½in., or 1in. in every 555 yards of heading, a very satisfactory result. In the Mont Cenis tunnel which is shaftless, the horizontal deviation is given as *nil*. But in the similar work at Mont St. Gothard, the total error amounted to 13in., or 1in. in every 627 yards, assuming the "thirl" to have taken place at about midway. In instituting this comparison, some additional credit may be fairly given to the St. Gothard tunnel, having regard to its great length, which closely approximates to nine miles and a-quarter.

◆

## RAILWAYS IN SIAM.

According to the United States Vice-Consul General at Bangkok, there are two railways in Siam, one from Bangkok to Pakwam, completed and opened in 1893, the other a royal line from Bangkok to Karat in the northern part of the kingdom, in progress. The former is 25 miles long, of 39·37in. gauge, and depends principally for its support upon the traffic between those two places. It was constructed with private capital, and is considered a success, being already able to pay dividends of 5 per cent. The latter is 140 miles long, one-third of which is completed. After surveys had been made, and plans and specifications prepared for this line, tenders were invited by advertisement in 1891 for its construction. Several American contractors, after receiving copies of the plans and specifications, refused to consider the matter, as in their opinion no one could construct the line unless he had some particular kind of old iron, and other obsolete stock which he could work off on such a contract, and that the whole thing, from start to finish, was absurd. In January, 1892, the contract, to include the completion and equipment of the line, with rolling stock, stations, freight and passenger accommodation, telegraph lines, and everything necessary to make a complete railway, was let to an English company for £625,000. The time for completion was fixed at five years. The work has been going on for 2½ years. The line pierced some of the finest rice producing territory in Asia, to which it will be of great benefit in bringing the product to the markets, a course now carried on by row boats on canals and rivers. Another, and probably the principal object of the line, is the development of the country beyond the hills of Karat, now practically wild. Its soil is said to be capable of producing as much as any other part of Siam. It is reported that the Government intends to extend the line some distance beyond Karat, its originally designed terminus. Among the many difficulties with which railway construction in Siam is attended are:—A general want of confidence between employers and employed, each seriously questioning the stability of the other; the question of labour, as coolies have to be imported from China at great expense, and it is doubtful after arrival whether they will go on with the work for which they were imported. As the demand for such labour in the city is considerable, and the wages are higher than those they would get from the railway, they frequently leave their importers in the lurch, and go to work in the city. As they are so much alike in general appearance, it is almost impossible to identify the fugitives among the vast crowds of their countrymen, and they are usually given up for lost. The work of building construction is very different from those of the United States. The coolies use hoes instead of picks and shovels, and baskets instead of horses and scrapers. All supplies have to be delivered by canal and river, and as these have to depend upon the tides, they are frequently left high and dry. The inability or unwillingness of the labouring classes to push matters is discouraging. There is nothing to be gained by hurrying them, as they take their time with everything. Malaria and other diseases are also serious obstacles to those stationed in the interior.

## THE MACHINERY TRADES AND THE AMERICAN TARIFF.

To the machinery trades of this country the new American tariff is likely to add industrial activity mainly by increasing the general prosperity of British and American industries. To American and English trade alike the removal of the uncertainty which has long overhung the tariff question is sure to mean revival. From this renewed vigour the machinery trades must obtain enlarged orders. But it is gratifying, too, that there is some chance of doing a better business with America direct in certain classes of machine tools and machinery. The tariff on imported machinery has been reduced from 45 to 35 per cent. *ad valorem*, and already a few of the Yorkshire machinists in particular are anticipating enhanced buying. The Americans can make practically all the woollen machinery they require, and no additional inducements offered to English makers would enable our home firms to obtain much of a footing in the States. In regard to specialities, such as jute and flax machinery, the conditions, however, are entirely different. Nearly all the flax and jute machinery used in America is supplied by this country, and mainly by Yorkshire. If, as seems likely, the jute factories become busier, the American manufacturers will most probably be under the necessity of increasing their resources and giving out additional orders. In that case, the almost inevitable result will be a larger demand for Yorkshire machinery, coupled with improved prices. That the machinery trade with America is worth cultivating is proved by the circumstance that last year the exports of all classes of machinery to the States were valued approximately at £666,000, of which £317,000 worth was textile machinery despatched in the first half of the year. The prospect of an increased trade in machinery with America, coming at a time when additional orders are reported at Glasgow locomotive works, and a development of business is noticeable among the railway material firms of the Sheffield centre, is very gratifying.

### WORK AND WORKERS IN BELGIUM.

AN observant Sheffield manufacturer who has just returned from the meetings of the Iron and Steel Institute at Brussels is of opinion that the principal cause why the Belgians beat us in several branches of the iron and steel trades is their cheap labour. In the round of the various works he saw nothing in the way of machinery superior to what we have in England—their forging presses he thought much inferior to those in Sheffield—but the men work ten hours a day, Saturdays included, for much lower wages than are given in England for eight hours a day. St. Monday—going off to cricket or football matches on Monday—is an unknown institution among the Belgians. Four shillings a day was about the highest wage he heard of. On the pit banks he saw women employed in large numbers. On one there were twenty females and three boys. The former were mainly from sixteen to forty years of age. Their wages were not one-half those of the men. At forty the females seemed to have ended their work, for none he saw were older. What becomes of them? The girder mills appeared to be fully employed, with Great Britain as their chief market. Some of the visitors were anxious to see through the sheet mills, of which a good deal had been heard, but none were open to inspection. The railway carriage and wagon mills were considered by the Sheffield manufacturer inferior to those in his own district. Everywhere there were signs that business was good, all the workshops seeming to be running full time. One feature of the pit and furnace life he noted and appreciated. At every place there was provision for the men divesting themselves of their working garb, thoroughly cleansing their persons, and walking away home in other apparel, leaving their soiled clothes behind them for next day's employment. This feature of Belgian industrial life he regards as capable of wider application in England. The gentleman whose opinions we reproduce has overlooked certain features of Belgian life, however, which tend to counterbalance the difference in wages. On this point we shall have something to say at another time.

## LITERATURE.

*A Practical Treatise on the Steam Engine.* By ARTHUR RIGG. London: E. and F. N. Spon. New York: Spon and Chamberlain. 1894.

THIS is a new edition of the book which was very warmly received when it first appeared in 1878—a book which was written for the practical engineer, but which has found even more readers among the students and teachers of the numerous technical colleges which now exist all over the world. When we reviewed it in 1878 we referred especially to the masterly and very practical way in which the author had dealt with numerous questions not previously treated, such as the influence of the reciprocating parts of steam engines as affecting the design and working of high speed, high-pressure engines.

Everyone practically interested in the design, construction, and performance of the steam engine will welcome this new and revised edition. Although the book is written from the point of view of the practical engineer rather than from that of the teacher in engineering colleges and schools, the author combines practical and theoretical instruction in his explanations of the essentials of a very large number of illustrations of engines and allied apparatus. He uses the illustrations more as examples than as designs to be slavishly copied, and throughout he gives that kind of information which enables the reader to apply workshop experience in modifying the designs to suit requirements. The part of the first edition which formed an essay on the forces developed by reciprocation has been extended by recent developments of the author's public system. The now common use of high speeds makes this essay more than ever valuable. In the sixteen years which have passed since the old edition was published, many changes have been made in steam engine design and practice, and some of these are illustrated by new plates, which are now increased to 103 in number. We could have wished that the author had replaced some of the designs of previously existing types by more modern examples. For instance, it would have been better to have replaced the portable engine, illustrated, by designs which better represent present practice, and especially we may refer to the portable engine of American design, which can only be inserted as an example of what not to do.

The author has now included a discussion of the experiments made by Mr. Willans, and an explanation of his straight line diagram. Mr. Rigg's readers could have dispensed with the three pages concerning Carnot's reversible heat engine theorem which leads him to the statement that a perfect steam engine working with a range of 200 Fah. will have an efficiency of 0·262. "That is," he says, "nearly three-fourths of the heat supplied to an engine working under the ordinary conditions, but supposed to be perfect, and therefore reversible, would be unavailable for conversion into work. It will thus be seen that the efficiency of an engine depends solely on the range of temperature within which it works." It is quite time that this sort of thing were omitted from books of the kind. There is nothing that makes it incumbent for a sane practical engineer to mix up the real engine with an ideal with which it cannot in the nature of things ever be comparable.

It may be mentioned also that the argument used concerning the effect of raising steam pressures, and the diagram used to illustrate it, leads the author, as it has done many who have preceded him, to incorrect conclusions. The area of the diagram may be increased by 28 per cent. by doubling the pressure, but the small expenditure of heat necessary to obtain this gain makes the gain well worth having. Willans' diagram—Fig. 2, Plate 3, "Proceedings" Institute Civil Engineers, vol. xciii.—might have been usefully referred to on this point.

These matters, however, do not affect Mr. Rigg's general treatment of steam in the steam engine as the various questions arise throughout the book in connection with compression, expansion, compounding, clearance, and allied matters affecting design.

There will, perhaps, always be some questions which an author of a book like this will treat inadequately, although he is known to be well versed concerning them. In speaking of governors, the author refers to one designed by Willans, and says:—"It dispenses with the evil known as hunting, and yet gives a regularity sufficient to satisfy the requirements of electrical engineers, although far from being so perfect a governor, in principle or in practice, as the Knowles governor previously described." This is all that is said on the question of hunting; and yet the author must have many times overcome the evil which everyone is most anxious to "dispense with."

Although Mr. Rigg has not entered at any very much greater length than previously into thermodynamic questions, we may predict for this new edition at least as favourable a reception as that which was accorded the first by the learner, the teacher, and the practical engineer.

*Progress in Flying Machines.* By O. CHANUTE, C.E. New York: The *American Engineer and Railroad Journal* Office. 1894.

WHEN Mr. Maxim read his paper recently before the Mechanical Section of the British Association at Oxford, Lord Kelvin, in the course of the discussion, took great pains to describe a small screw-propelled flying apparatus of toy proportions which had been made some years ago by his brother, the late Professor James Thompson. Mr. Maxim had described the aëroplane flying machine, so fully described in our impression of the 10th inst., and Lord Kelvin expressed his belief that a better flying machine could be constructed by using the powerful screw propellers which Mr. Maxim had described, but on vertical instead of horizontal axes. The little machine which his brother had made consisted of two small screws, revolving in opposite directions, and driven by twisted elastic india-rubber. James Thompson was deterred from pursuing what he had done in this direction under the impression that the atmospheric resistance experienced by propellers and things propelled was very much greater than it is now known to be, and was indeed known to one writer at least, namely, Sir John Robison, even before James Thompson's time.

In connection with the recently renewed attention to aërial navigation, the book before us is of considerable interest, as furnishing a concise and clear account of a large proportion of all the known work of an experimental kind which has been done with the object of making a flying machine. It is noteworthy that, amongst the machines designed many years ago, namely, in 1845, was one which precisely anticipated the form suggested by Lord Kelvin and claimed as a development of his brother's invention. It was made by a Mr. Cossus, who was, however, anticipated by Mr. John Bourne, who tried models with screws, but gave up his experiments because no motive power appeared to be forthcoming.

More recently, Dienaide, a well-known French engineer, made many experiments about the year 1871, followed by several others, including Forlanini, who in 1878 made a small flying machine driven by a little steam engine. With this model Forlanini obtained a good many figures with regard to the lifting power of screws working in air. Edison subsequently made some experiments, but he was not so successful in aërial mechanics as he has been in electro-mechanics. At present the lifting power obtained by Mr. Maxim by means of aëroplanes and horizontally acting screws, namely, 2·5 lb. per square foot of plane, is greater than has been obtained by any other experimenter, and the thrust obtained by his screws is by far the greatest yet achieved. According to Mr. Maxim the friction of these screws in air is almost unappreciable—an experimental observation which is confirmed by Professor Langley, but some experiments carried out some time ago by Mr. Vogt prove that previous observers were not so fortunate in this respect. There is plenty of room for opinion as to the relative merits of the aëroplane and the vertical screw for lifting and propulsion, and at present it seems to be more easy to make a machine that will fly than to predicate its behaviour or its management if allowed to fly. It is quite possible that with regard to this part of the problem of flight a good deal will have to be learned on the lines of the successful experiments of Herr Otto Lilienthal, who has constructed a system of dirigible wings by means of which he has successfully flown considerable distances in the air by springing from elevated positions, or by getting a sufficient impetus by running down part of a steep hill, and in this way getting his wings spread, and then floating off after the manner of the flight of sea birds without wing motion. To learn to fly by wings such as those devised and used by Herr Lilienthal will be a matter for gymnastic exercise and persistent effort, much as is the performance of many feats by acrobats, and even the learning to ride a bicycle; but it is not improbable that the commencement of human flight may be by these means.

*Tidal Rivers: Their Hydraulics, Improvement, and Navigation.* By W. H. WHEELER, M. Inst. C.E. London: Longmans, Green, and Co. 1894.

IT can hardly be said that the past half century has made any very material additions to the essentials of the science of the hydraulics of rivers. Since the writings of Robinson, David and Thomas Stevenson, Rennie, D'Arcy, and Bazin, none of very remarkable character have been published. There is not perhaps room now for any very novel treatment of this part of the subject, and the chief purpose of modern literature upon it has been to present in a more concise form, the available theory of river and harbour engineering in connection with modern facilities for carrying out works on a large scale with the modern machinery and materials, and also to give examples of recent works and a record of the results of their existence. In this sense Mr. Wheeler's book will be welcomed as a valuable aid to engineers and others interested in the hydraulics, improvement, and navigation of tidal rivers. It commences with an excellent notice of the development of hydraulic science from the point of view of the river and harbour engineer, and this is followed by an historical account of works carried out for improvement and navigation. Mr. Wheeler is of a severely practical turn of mind, and any one reading his chapters on the motion of water in tidal rivers, and on the transporting power of water, will soon find that he does not waste time or space on controversial and academic questions, but quietly deals with that which is useful and necessary, and simply drops any theory or hypothesis which time has proved untenable. In the chapters on the tides and physical condition of tidal rivers, bars at their mouths, principles to be observed in their improvement, and on littoral drift, there is much which is due to his personal observation and experience. This is also true concerning the chapter on dredging, in which the various modern methods mostly followed, and particularly the method of removal and maintenance by erosion and pumping, are dealt with in a practical way as the result of experience. In the chapters on the requirements of navigation and the buoying and lighting of tidal rivers, we have extensions of the articles by the author which have appeared in THE ENGINEER.

A chapter on surveying tidal rivers and estuaries is followed by one on what is probably quite a modern proceeding in connection with the hydraulics of estuaries, namely, the employment of working models for investigating the action of currents and the travel of sand, a method due to Professor Osborne Reynolds, and followed up by a committee of Section A of the British Association, of which Mr. Wheeler was a member. Since this time Mr. Vernon Harcourt has experimented with a model of the Seine, and the author has with models of other river estuaries, and the result of the experiments is a confirmation of the belief that results fairly approximating those actually occurring are artificially obtained.

Mr. Wheeler's book concludes with accounts of examples of river improvement in Great Britain and on the Continent, and, with appendices, giving titles of books relating to tidal rivers, French and English hydrographic and nautical equivalent terms, abbreviations used on marine charts, &c. &c. It is one of those books which those concerned must possess.

*Elementary Lessons with Numerical Examples in Practical Mechanics and Machine Design.* By ROBERT GORDON BLAINE, Assoc. M. Inst. C.E. London: Cassell and Co. 1893.

THIS is a revised edition of a very useful little book, founded on the lectures and system of teaching adopted under Professor John Perry at the Finsbury Technical College. A careful examination of its contents confirms the remark made in an introduction by Professor Perry, in which he says the exercises are framed "to fix firmly in the mind of the student the fact that a certain principle is of importance outside the examination rooms. He is not tempted to calculate in cases where actual experimental trial and observation will show him the best solution of a problem; and when he works out an answer which every practical illiterate mechanic knows to be ten times too great, he will not complacently rest satisfied with this absurd answer, and talk about its being 'theoretically right.'" It opens with the estimation and summation of quantities by the polygons of forces, the terms being explained according to modern notions, but with examples which make things clear. Work and energy questions are dealt with in units common in the "British Engineer's" world; and velocity ratio and mechanical advantage are illustrated by drawings of real screw and hydraulic jacks and a crane, so that a practical notion of these things is learned with what used to be called the natural philosophy of such things. Power, efficiency, &c., are learned with reference to measurement of electrical quantities, flow of a stream and its power, water through a turbine, and so on, power from an indicator diagram, and power for traction purposes. The questions following the lessons on force, mass, acceleration, and the kinetic energy of rotating bodies relate to flywheels for steam and gas engines, with different permissive variations from uniform velocity. Belt driving, and dynamometers as work-measuring machines receive adequate treatment; and that of the strength of beams, springs, and the steam engine, make it an elementary treatise on practical mechanics which one would wish to place in the hands of a student.

### BOOKS RECEIVED.

*Theoretical Mechanics' Fluids.* By J. Edward Taylor, M.A., B.Sc. (Lond.) London: Longmans, Green, and Company. 1894.

*Particulars of the Warships of the World (extracted from Lloyd's Register Book,* 1894-95.) London: 2, White Lion-court, Cornhill. 1894.

*Chats on Invention.* Being an attempt to train the faculties of invention. By John Martin. London: Offices of *Invention.* 1894.

*A Record of the Transportation Exhibits at the World's Columbian Exhibition of* 1893. By James Dredge. London: Offices of *Engineering;* and New York: Jno. Wiley and Sons.

*The Next Naval War.* By Captain S. Eardley-Wilmot, R.N. With an illustration by Chevalier E. De Martino. Second edition. London: Edward Stanford. 1894.

*Forty-first Report of the Department of Science and Art of the Committee of Council on Education, with appendices.* London: Printed for her Majesty's Stationery Office by Eyre and Spottiswoode. 1894.

*The Working and Management of an English Railway.* By the late Sir George Findlay, general manager of the London and North-Western Railway. Fifth edition, revised and enlarged, with portrait and biographical sketch. Edited by S. M. Philp. With numerous illustrations. London: Whittaker and Company. 1894.

## THE NAVIGABLE BALLOON AT THE ANTWERP EXHIBITION.

The time when exhibition authorities relied solely, or even principally, on exhibits to attract the public has long passed. They now depend on music, flowers, fountains, and fireworks, but above all, on "side shows." A successful attraction like the Eiffel Tower, or the Ferris Wheel, is not only a fortune to its promoters, but is effective as an advertisement, and will bring thousands to an exhibition who take no special interest in anything shown in the galleries.

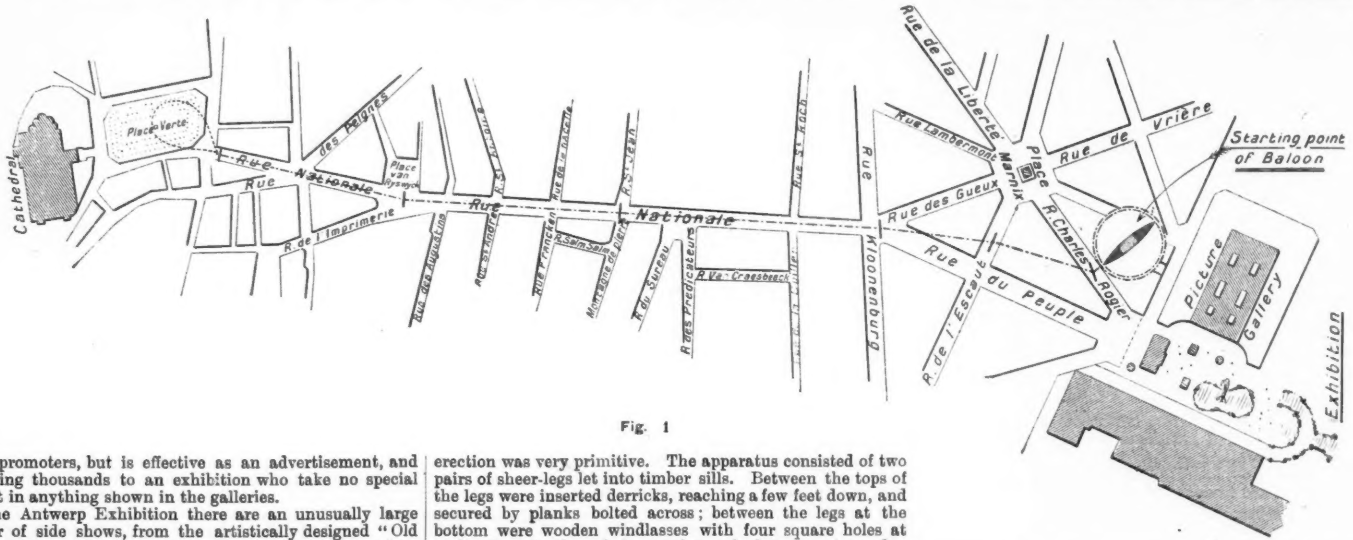

Fig. 1

At the Antwerp Exhibition there are an unusually large number of side shows, from the artistically designed "Old Antwerp" down to the usual allurements of a country fair. But the great attraction, or what the French call the *clou* of the whole Exhibition, was to have been the navigable balloon. In the design of this balloon, and the arrangement of its accessories, there is nothing which should render it impossible to ascend, and to be driven by electricity from the Exhibition grounds to the Place Verte, provided there is little or no side wind; but whether its inventor will be able to steer it against lateral pressure, and turn it at the end of its course, is a question that nothing short of actual experiment can decide. In any case, as from various unforeseen accidents the balloon is even yet not quite ready, its completion will not be of much use in drawing the general public to the Exhibition, though as a scientific experiment it will be not less interesting than if it had been in working order at the beginning of May.

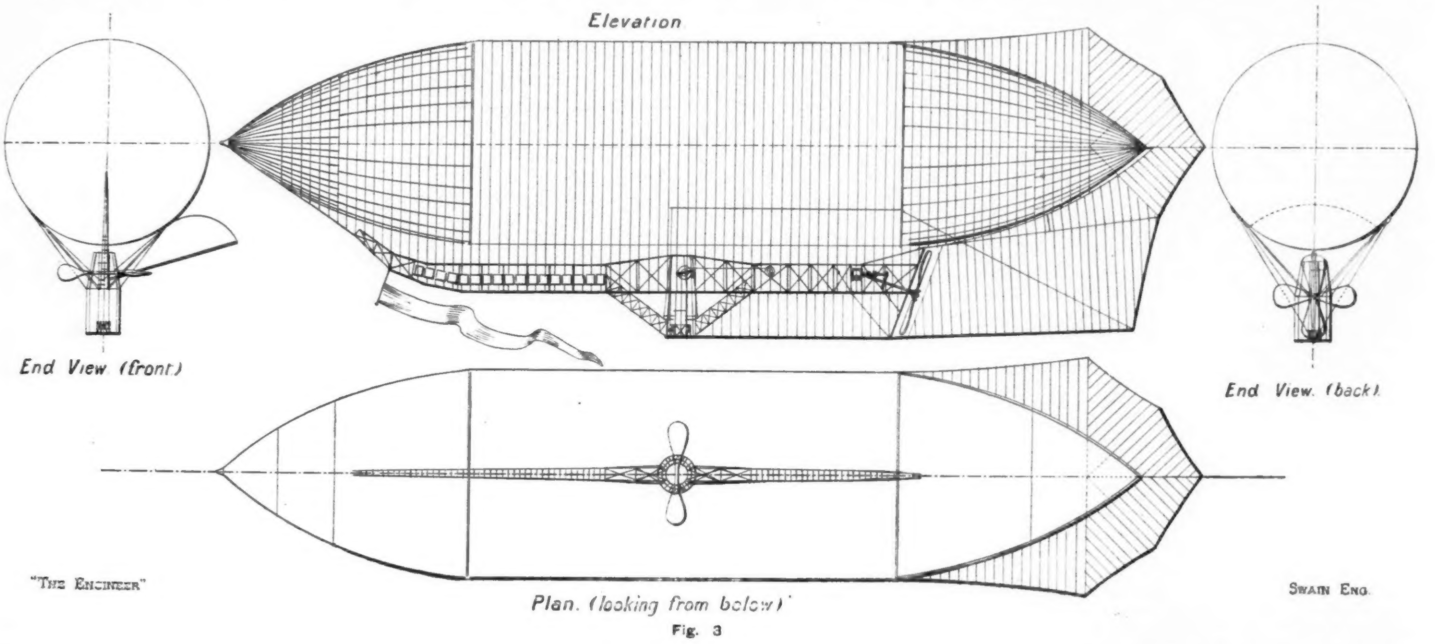

Fig. 3

The chief point of difference between this balloon and all those which have preceded it is in the method of applying the motive force. Instead of turning the propeller by hand, or by steam or other power generated in the car, it is to be worked by electricity, conveyed to the balloon through a flexible cable from dynamos at a central station. Practically, the principle is the same as with electric tramways, except that the balloon will resemble a tramcar without brakes. But it will be subjected to another difficulty from which tramcars are exempt: it will not always be easy to maintain electric connection, whilst it will be extremely difficult to re-establish it if accidentally interrupted whilst the balloon is in the air.

The electricity is generated by a pair of 200-horse power gas engines, made by Messrs. Fielding and Platt, driving dynamos which, with switches and other electric fittings, have been supplied by the Oerlikon Works. To obtain gas for these engines, as well as for inflating the balloon, a complete plant has been erected by the Dowson Economic Gas and Power Company, of Westminster.

It was at first intended that the balloon should travel from the Exhibition to the Bourse, on the roof of which there was to be a station; it was also proposed in some instances to carry the cables on the tops of existing telegraph poles. But the postal authorities not only refused to sanction the use of the poles, but objected to the cables crossing any lines of wire; so a shorter and straighter route had to be selected. It was then decided—see dotted line on Fig. 1—to go straight down the Rue Nationale, which enters the Place Verte on the opposite side to the Cathedral, to turn the balloon above the Place Verte, and to return by the same route to the starting point. Six steel lattice trestles, 100ft. high, were erected last May to carry the cables. They span the road from pavement to pavement, having an average width of 80ft. Fig. 2 shows the trestle at the end of the Rue Nationale furthest from the Exhibition; the others are less ornate. They are all made of 3½in. by 3½in. by ⅜in. angles, with 2in. by ⅜in. flat plates; the legs being 20in. square at the bottom, and 12in. square at the top. They were each put up in one piece, and the method of erection was very primitive. The apparatus consisted of two pairs of sheer-legs let into timber sills. Between the tops of the legs were inserted derricks, reaching a few feet down, and secured by planks bolted across; between the legs at the bottom were wooden windlasses with four square holes at each side. In these holes workmen had to insert wooden capstan bars, climb up, and by means of their own weight hanging on the bars, turn the windlasses. The arrangement of the top of the trestles will be seen more clearly from the drawing of the trolley—Figs. 4 and 5. The current is conveyed from the generating station by three parallel cables of galvanised steel wire an inch in diameter. These, which are each 1400 yards long, are in one piece, and were made by Messrs. Bullivant and Co., of Mark-lane.

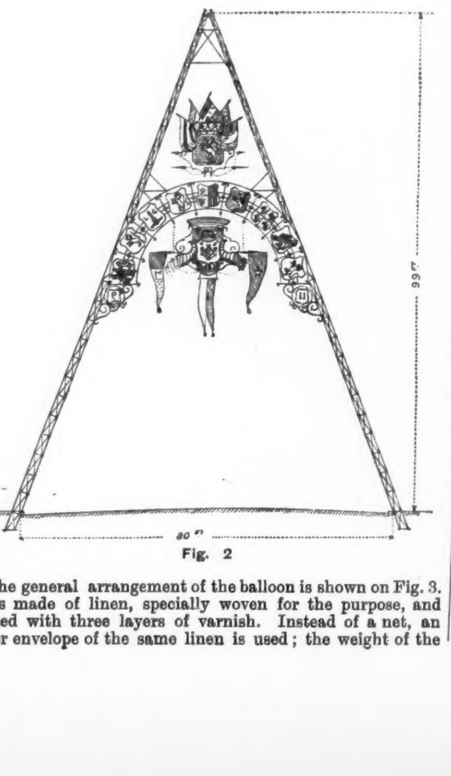

Fig. 2

The general arrangement of the balloon is shown on Fig. 3. It is made of linen, specially woven for the purpose, and coated with three layers of varnish. Instead of a net, an outer envelope of the same linen is used; the weight of the double covering being about four tons. It is spindle-shaped, 57ft. in diameter, and from the foremost point to the end of the rudder measures 284ft. Its cubic capacity is 500,000ft. A valve at the top for letting out the gas has a papier-maché frame. It is 4ft. diameter, and weighs only 70 lb. The car is made of steel gas piping, covered with wickerwork, and as may be seen by the illustration, it is of very peculiar shape. The centre is cylindrical, 8ft. in diameter, and reaches down much lower than the front and back portions. Of these the front is intended for passengers; it is entirely closed, but with windows. The back is for the crew, and contains the dynamo for transmitting the power to the screw; it is shown on Fig. 6, and is also from the Oerlikon Works. Its casing is of papier-maché, and though it is capable of transmitting 125-horse power, its weight is a little under a ton. The screw has four blades, its diameter is 26ft., and M. Léon Champy, the inventor, has calculated that in calm air the balloon will be able to travel twenty-five miles an hour, and that consequently he will have sufficient force at his command to be able to drive the balloon against a strong wind. The connection between the three cables and the dynamo in the car is made by an elastic cable, which passing over a drum with an automatic coiling arrangement in the car, terminates in the trolley shown on Fig. 4. The captain's station is in the cylindrical central portion of the car, and from it he will be able to increase or diminish the speed of the balloon, as well as to raise, lower, and steer it.

Antwerp is not the most suitable locality that could be found for aëronautical experiments, as the sudden gusts of wind from across the Scheldt will make steering more difficult than it would be in a steady breeze. It is also to be regretted that a course could not be chosen in which it was not necessary to make such a sudden turn of the balloon, as will be required at the Place Verte, and that the experiment was not first tried with a smaller balloon, so that the resistance to side winds might be less. Still, we hope to be able to report in a few weeks that M. Champy has had a satisfactory trial run, for it is certain that if aërial locomotion succeeds at Antwerp, it will soon be tried elsewhere over a longer course.

---

Transportation Exhibits at the Chicago Exhibition.—We have received a copy of the contents and preface of "A Record of the Transportation Exhibits at the World's Columbian Exposition of 1893," by James Dredge. The preface promises a great deal that will be of undoubted interest to all those who are interested in or connected with transportation by railways, and readers generally will agree with the author in his estimate of the extent to which the world of to-day is dependent for almost everything upon facility of communication by railway and by steamship. The book which is to contain this record will be published at the offices of *Engineering*, and by Messrs. John Wylie and Sons, New York. The index shows that the record is intended to cover even more ground than its title indicates.

"THE ENGINEER" SWAIN ENG.

## METHODS OF DETERMINING THE DRYNESS OF STEAM.[1]

By W. C. UNWIN, F.R.S., M. Inst. C.E.

(*Continued from page* 178)

IV. *Continuous condensing method.*—The difficulties of the ordinary condensing method have led Mr. Barrus, Mr. Hoadley, and other observers to adopt a process of continuous steady condensation. The steam may be condensed ($\alpha$) in the condensing water, or ($\beta$) in a surface condenser. The first method[10] may be carried out by the apparatus shown in Fig. 3. The steam passes from the steam pipe S to a small injector $i$. The condensing water is drawn from the tank A, and the mixed water and condensed steam are discharged into the tank B. If $W_1$ is the decrease of weight of A in any interval, and $W_2$ the increase of weight of B, then $w = W_2 - W_1$ is the weight of steam condensed. Thermometers $t$, $t$, give the temperatures of the water entering, and mixed steam and water leaving the injector. Let $t_1$, $t_2$ be these temperatures, and $t$ the temperature of the steam. Then, if $x$ is the dryness fraction,

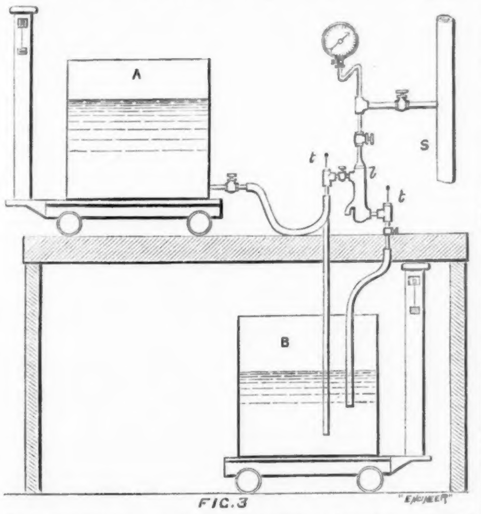

FIG. 3

$$w\left\{(t-t_2)+x\,L\right\}=W_1\,(t_2-t_1)$$

$$x=\frac{\frac{W_1}{w}\,(t_2-t_1)+t_2-t}{L}$$

$$=\frac{\frac{W_1}{w}\,(t_2-t^1)+t_2-t}{1116-0\cdot71\,t}$$

Mr. Barrus has used a surface condenser—Fig. 4—consisting merely of a short vertical pipe in a vessel through which cooling water circulates. The condenser is supplied with cooling water at a fixed rate of flow. Then, as the condensing surface is constant, the rate of condensation is constant, and the rise of temperature of the cooling water is constant. Condensation is carried on for any convenient period, and the condensed steam run off for weighing. Simultaneously a series of readings are taken of the temperature of the water entering and leaving the condenser, and of the condensed steam. The radiation correction can be determined by observing the fall of temperature in the condenser when the supply of steam and cooling water is stopped.[11] The continuous condensing method seems likely to be more accurate than the ordinary method, but the arrangements are more complicated.

V. *Method by superheating.*—Mr. G. H. Barrus about 1890 devised a calorimeter in which the steam to be tested passed through a chamber jacketed with superheated steam. The steam was thus dried and superheated. The quantity of heat required was inferred from the fall of temperature of the superheated steam. The orifices of the inner steam pipe and outer jacket ware equal, so that the same weight of steam passed through each. Hence no weighing was necessary. If $t_1\,t_2$ are the temperatures of the superheated steam entering and leaving the jacket, and $t_3\,t_4$ the temperatures of the steam entering and leaving the inner chamber, then the superheated steam in the jacket has lost $t_1-t_2$ degrees of temperature, and the sample steam has been dried and superheated $t_4-t_3$ degrees. If $x$ is the dryness fraction and L the latent heat of the steam in the inner chamber,

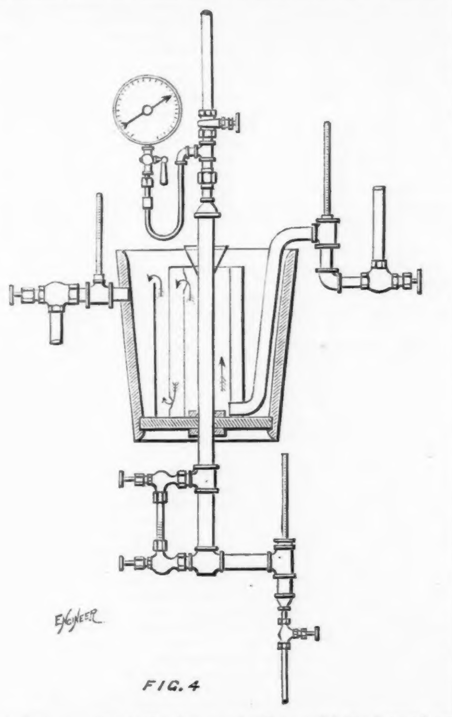

FIG. 4

$$0\cdot48\,(t_1-t_2-l)=L\,(1-x)+0\cdot48\,(t_4-t_3)$$

$$1-x=0\cdot48\,(t_1-t_2-l--t_4+t_3)\div L$$

$l$ is a small correction for radiation. Only four thermometer readings are necessary for a determination. The calorimeter is only suitable for nearly dry steam, and appears to be superseded by the simpler throttling and separating calorimeters. A description will be found in "Boiler Tests," Barrus, Boston, 1891, page 18, and in "Experimenal Engineering," Carpenter, page 386.

VI. *The wire-drawing method.*—This was first proposed by Professor Peabody. Mr. Barrus and others have devised modified forms of the apparatus. It depends on the principle that slightly moist steam is superheated by wire-drawing. Fig. 5 shows Mr. Barrus's arrangement[12] of the apparatus. The steam passes from a chamber A to a chamber B through a very small aperture—$\frac{1}{18}$in. in diameter. The full steam pressure is in A, and the pressure in B differs little from atmospheric pressure. Thermometers $t$, $t$, give the temperatures of the chambers. Let $t_1\,t_2$ be the temperatures of the steam before and after wire-drawing, and $t_3$ the temperature of saturated steam corresponding to the pressure in B. $_2-t_3$ is the amount of superheating of the steam in B. Let $h_1$, $L_1t$ be the liquid heat and latent heat of steam at $t_1$; $h_3$, $L_3$, corresponding quantities for steam at $t_3$.

$$h_1+x\,L_1=h_3+L_3+0\cdot48\,(t_2-t_3)$$

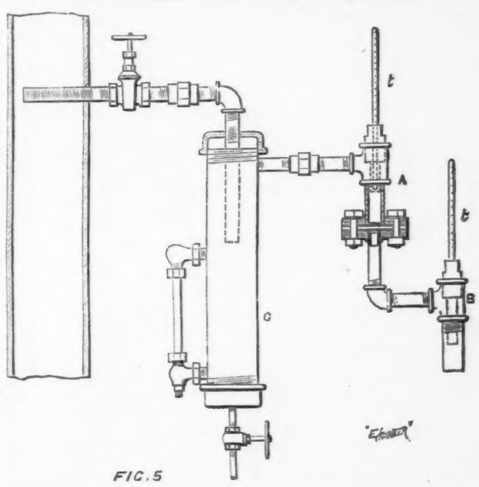
$$x=\frac{h_3-h_1+L_3+0\cdot48\,(t_2-t_3)}{L_1}$$

Or taking the specific heat of water constant:—

$$x=\frac{t_3-t_1+L_3+0\cdot48\,(t_2-t_3)}{L_1}$$

$$=\frac{1116-t_1-0\cdot19t_3+0\cdot48t_2}{1116-0\cdot71t_1}$$

No weighing is required, and temperatures only have to be observed. The apparatus must be in operation for twenty to thirty minutes before observations are commenced. Then observations may be begun and continued for as long a period as is desired. It is not a mere small sample of steam, therefore, which is observed, but a considerable quantity taken from the steam pipe at a uniform rate. The observations are as simple as possible, and the apparatus is used with the greatest facility. Presently some tests will be given tending to show that the instrument is very trustworthy. Suppose the steam is initially quite dry. Then $x = 1$ in the formula above.



FIC. 5

$$h_1+L_1=x_3+L_3+0\cdot48\,(t_2-t_3)$$

$$t_2=0\cdot604t_1+0\cdot395t_3$$

From the small excess of pressure over atmospheric pressure $t_3$ is about 214 deg. Then

$$t_2=0\cdot604t_1+84\cdot5.$$

This may be termed the normal temperature in the chamber B for dry steam. In proportion as the temperature falls below this the steam is initially moist. If it contains initially more than a certain amount of moisture, the temperature in the chamber falls to 214 deg. or below it, and no calculation of the dryness is possible. If $t_2 = 220$ deg. and $t_3 = 214$ deg. are taken as the limiting values for which the instrument can safely be used, there being then 6 deg. of superheating in B, then

$$x_{\min}=\frac{1181-t_1}{1116-0\;71t_1}$$

and

$$(1-x)_{\max}=\frac{0\;29t_1-65}{1116-0\;71t_1}$$

give the minimum initial dryness or maximum amount of initial moisture in steam for which the apparatus is suitable.

| $t_1 =$ | Greatest initial moisture per cent. |
|---|---|
| 250 deg. | 0 80 |
| 300 deg. | 2 44 |
| 350 deg. | 4 21 |
| 400 deg. | 6 13 |

VII. *Combined separating and wire-drawing method.*—To extend the usefulness of the wire-drawing method Mr. Barrus added a separator—C, Fig. 5. The steam first passes through the separator, leaving most of its moisture, and the remainder is measured by a wire-drawing calorimeter. When thus arranged the use of the instrument is much more complicated, as the amount of steam flowing through and the amount of moisture separated must be weighed. A condenser must therefore be used, at any rate occasionally, to determine the amount of steam flowing in a given time. Assuming the orifice to remain unchanged, a formula can be found for the weight of steam discharged per minute at any given pressure.

VIII. *Superheating by addition of heat.*—A method has been proposed by Mr. W. R. Cummins,[13] in which a vessel of constant volume is used, completely surrounded by a steam jacket. Steam is at first blown through both jacket and vessel till there is a fair sample of the steam to be tested in both. Next the jacket and vessel are cut off from the steam pipe and from each other. The steam in the jacket is then heated by compression—by a steam compressing pump—or by heating. The simultaneous rise of pressure and temperature in the vessel containing the sample of steam are observed. While moisture is evaporating the relation of pressure and temperature will follow Regnault's law. From the moment when superheating begins the pressure will increase much less rapidly with the temperature. Let $t_1$ be the temperature of the sample of steam initially, $t_2$ the temperature at which superheating is observed to begin, $v_1$ $v_2$ the corresponding specific volumes of dry saturated steam, $x$ the initial dryness of the steam, V the volume of the vessel, and $w$ the weight in pounds of steam admitted. Then

$$V = x\,v_1\,w = v_2\,w$$

$$x = \frac{v_2}{v_1}$$

where the specific volumes $v_2$ $v_1$ can be calculated from the observed temperatures $t_2$ $t_1$. The method is quite accurate in principle, but it would involve considerable skill to carry out accurately, and it does not appear to have been actually tried.

IX. *Chemical methods.*—These suppose that some soluble salt is added to the boiler water so as to form a solution of known strength, and that of all the feed supplied to the boiler part is evaporated and flows away as steam, part as priming water. The former removes no salt; the latter is of the saltness of the water then in the boiler. Hence, either the decrease of saltness of the boiler water or the amount of salt present in the steam can be used in determining the amount of priming water in the steam. Most commonly table salt (NaCl) has been used because the amount in solution can be easily determined by the nitrate of silver method. In other cases sulphate of soda has been used, the sulphuric acid being determined by precipitating with chloride of barium. It is convenient to describe three variations in the way in which the chemical method is applied.

(*a*) *Decrease of saltness of the boiler water measured.*—Salt is introduced with the feed till the boiler water contains 1 or 1½ per cent. of salt. Then, during a test in which the amount of feed is measured, a sample of the boiler water is drawn off at the beginning and end of the test. Care must be taken that the level of the water in the boiler—as shown by the gauge glass—is exactly the same, when the two samples are taken. Let W be the weight of water in the boiler, and $s_1$ $s_2$ the percentage of salt in the two samples. The amount of salt removed from the boiler during the test is $W\,(s_1 - s_2)\,/\,100$. Let $w$ be the amount of feed supplied, and $x$ the dryness fraction of the steam. Then $x\,w$ lb. of pure steam are generated, and $(1-x)\,w$ lb. of priming water carried over. The mean saltness of the priming water is $(s_1 + s_2)\,/2$. Hence

$$\frac{(1-x)\,w}{100}\,\frac{s_1+s_2}{2} = \frac{W}{100}(s_1 - s_2)$$

$$x = 1 - \frac{2\,W}{w}\,\frac{s_1 - s_2}{s_1 + s_2}.$$

The method deals with the whole amount of steam produced, and not with mere samples of it. On the other hand, the disadvantages of the method are:—(1) It measures only priming water mechanically projected into and carried by the steam, and not moistness produced in other ways. (2) Great exactness of analysis is necessary, the difference of saltness being a small quantity. (3) The feed, being continuously supplied at one part of the boiler, tends to produce, in spite of the circulation, a non-uniform distribution of saltness throughout the mass of water in the boiler. If the saltness is not uniform, the difference of saltness of the samples gives a quite erroneous result. If there is salt in the feed-water, it can be allowed for. This method was first used at Mulhouse in 1859; much later it was revived, and is often called Brauer's method.

β. *Percentage of salt in the steam determined.*—At intervals during a test, samples of the boiler water are taken, and at the same time some steam is condensed in a small surface condenser. Equal quantities of the water samples are mixed together, and also equal quantities of the condensed steam. Let $s_1$ be the percentage of salt in the averaged sample of boiler water, and $s_2$ that in the averaged sample of condensed steam. If $x$ is the dryness fraction of the steam, each pound contains $x$ lb. of steam and $1-x$ lb. of water of the saltness of the boiler water.

$$(1-x)\,s_1 = s_2$$

$$x = 1 - \frac{s_1}{s_2}$$

The disadvantages of this method are:—(1) That very small portions of the steam are tested, and as the mechanical action producing priming is probably irregular, it is very uncertain whether they fairly represent the average condition of the steam. (2) The accurate determination of $s_1$ can only be made if the boiler water is uniformly salt. (3) The amount of salt in the steam is very small compared with that in the boiler water, so that the accurate determination of $s_2$ is difficult.

γ. *Escher's method.*—A quite different method of considerable interest has been proposed by Mr. R. Escher, of Zurich.[14] Mr. Escher considered the case of a boiler fed with impure water. Of the salts in solution some are thrown down as incrustation, others remain in solution. In the boiler water during working there is a steady concentration of these soluble salts, which tends towards a fixed limit. At this limit the priming removes as much salt in the form of concentrated boiler water as the feed brings in. Let $s$ be the saltness of the feed-water in pounds per pound of water, and $k$, the saltness at any given time of the boiler water. Then each pound of steam removes $(1-x)\,k$ lb. of salt, while each pound of feed introduces $s$ lb. of salt. In steady working when the limit is reached

$$(1-x)\,k = s$$

$$x = 1 - \frac{s}{k}.$$

Let $k/s = c$, the ratio of concentration of the boiler water. Then, for example, if the boiler water contains twenty times as much salt as the feed, $x = 1 - \frac{1}{20} = 0{\cdot}95$ or the steam contains 5 per cent. of priming water. The method assumes that the feed contains a definite percentage of easily soluble salt, and that the trial has continued till the maximum concentration is reached. But if the boiler is freshly filled it may be a long time before the limiting condition is reached. Let W be the quantity of water in the boiler in pounds, and F the quantity of feed per unit of time. Let $k$ be now the saltness of the boiler water at $t$ from the beginning of the test. In a short interval $d\,t$ the quantity of salt $F\,s\,d\,t$ enters the boiler with the feed, and the quantity $F\,(1-x)\,k\,d\,t$ is carried away in the priming water. The increase of salt in the boiler is therefore

$$W\,d\,k = F\,[s\,d\,t - (1-x)\,k\,d\,t).$$

Let $W/F = a$. Then

$$a\,d\,k + (1-x)\,k\,d\,t - s\,d\,t = 0.$$

Integration gives $$k = \frac{s}{1-x} + \frac{C}{e^{\frac{1+x}{a}t}}$$

The constant of integration is obtained by putting $k = s$ when $t = 0$.

Let also $\frac{1+x}{a}\,t = n$. Then

$$s = \frac{s}{1-x} + C$$

$$k = \frac{s}{1-x}\left(1 - \frac{x}{e^n}\right)$$

$$c = \frac{k}{s} = \frac{1}{1-x}\left(1 - \frac{x}{e^n}\right)$$

From this equation, $c$ being ascertained by analysis of the boiler, water, $x$ can be determined at any period of the test. As the equation is not easily solved $x$ may be approximated to thus. If $c$ is the concentration after $t$ hours working, a first approximation to $x$ is $$x_1 = 1 - c.$$
Put this in the expression above for $c$; a value $c_1$ will be obtained which would be the concentration in the time $t$ if $c$ were the limiting concentration. Then assume

$$\frac{c}{c_1} = \frac{c_{max}}{c}$$

$$c_{max} = \frac{c^2}{c_1}.$$

This an approximate value of the maximum concentration in unlimited time. A second approximation to $x$ is

$$x_2 = 1 - \frac{c_1}{c^2}.$$

Mr. Escher has not directly suggested how his method could be used in the case of a boiler fed with pure feed-water, or, say, with water containing too small an amount of chloride to give a sufficiently rapid concentration. But it might easily be applied by pumping in with the feed at intervals of an hour a known quantity $w$ of a saturated salt solution. The quantity $w$ might be so arranged that the concentration at the end of the test was such that the boiler water contained about 1 per cent. of salt. A preliminary assumption as to the amount of priming would have to be made in settling what quantity of salt to introduce. The salt method by measuring the decrease of saltness of the boiler water was first used at Mulhouse in 1859. In the trials then it failed to give satisfactory results. In some of the tests an apparent increase of saltness of the boiler water was found which must have been due to the saltness being ununiformly distributed in the boiler. At Düsseldorf in 1880 the method of measuring the salt in the steam was tried, sulphate of soda being used.[15] Ten samples of boiler water and condensed steam were taken in each test. The results were discrepant, giving 0·21 to 9 per cent. of moisture in the steam in different tests.

*Use of the salt method in the Berlin trials of portable engines in* 1883.—The most careful tests by the salt method which have been found are some made by Dr. Bunte in Munich, in some trials of portable engines under the direction of a commission appointed by the German Government.[16] In these tests both the decrease of saltness of the boiler water and the amount of salt in samples of condensed steam were determined. They throw some light, therefore, on the relative trustworthiness of the two proceedings. Concentrated salt solution was introduced into the boilers before beginning a test till the boiler water contained 1 to 1½ per cent. of salt. At the beginning of each trial, and with the water at normal level in the gauge glass, a sample of boiler water was taken; at some intermediate times and at the end of the trial similar samples were taken. The boiler water was taken from the gauge cock. To prevent evaporation in taking the sample it was drawn off through an india-rubber tube into a vessel containing 500 c.c. of cold distilled water. Exactly 500 c.c. of boiler water were drawn off, so that the sample had half the saltness of the boiler water. The chlorine was determined by a nitrate of silver solution containing 10 per cent. of normal solution, with the addition of chromate solution as an indicator. For the steam samples the steam was taken from a cylinder or valve chest cock. From 200 to 1000 grammes were condensed at intervals of about an hour. In Trial I., on the Dolberg portable, the boiler water samples showed the same saltness at the beginning and end of the test. Intermediate samples showed very slight variations, attributed by Dr. Bunte to variations of water level in the boiler. In five samples of condensed steam an addition of 0·2 to 0·3 c.c. of silver solution gave a colour reaction. Dr. Bunte calculates that the priming must have been less than 0·1 per cent. Both methods, therefore, showed that there was practically no priming. Identically similar results were obtained in trials of four other boilers. But in one trial there was considerable priming. In Trial IV., on Siegel's portable, the sample of boiler water taken at the beginning showed 199 c.c. of 10 per cent. of normal salt solution, and that at the end 191 c.c. per 100 c.c. This corresponds to a loss of 4 per cent. of the salt in the boiler, or to 1·7 per cent. of priming. In the steam tests different samples yielded 24·3, 20·3, 6·8, 4·0, 0·3, 0·2, 0·3, 25·5, and 7·3 c.c. of 10 per cent. of normal salt solution per 100 c.c. of condensed steam. After thoroughly cleansing the apparatus by blowing through, 2000 grams of steam were condensed, and gave 9 c.c. per 100 c.c. The amount of salt in the steam was therefore extraordinarily variable. The highest result, 25·5 c.c., per 100 c.c., corresponds to 12·8 per cent. of priming. Dr. Bunte thinks that foaming occurred. It will be seen that in most cases the salt test fails to indicate any appreciable priming. It must be inferred that the mechanical mixture of boiler water with the steam is ordinarily an action of insignificant importance. In one trial where there was great priming, shown by the working of the engine as well as by the salt test, the results are extremely discrepant, and apparently Dr. Bunte thinks that the real amount of priming was greater than the salt tests indicate. The salt test was used in some tests of boilers at the Frankfort Exhibition, in 1891, by a committee presided over by Dr. Schröter[17]. The tests lasted eight days for each boiler. Salt was fed into the boiler till the boiler water contained about 1½ per cent. After the boiler had been working a day two samples were taken, one of the boiler water from near the evaporating surface, one from the nearest water separator in the steam pipe. The samples were drawn off through a cooling pipe to prevent evaporation. The amount of salt in the samples was determined by the nitrate of silver test, and also that in the feed supplied to the boilers. The following table gives the results:—

*Determination of Priming by Salt Test in Trials at the Frankfort Exhibition*, 1891.

| Name of Boiler. | Feed-water used. | Salt in boiler water, per cent. | Salt in water from steam pipe, per cent. | Salt in feed-water, per cent. | Moisture in the steam, per cent. |
|---|---|---|---|---|---|
| 1. Essen Cornish .. | Ordinary Water Co. | 1·524 | 0·00116 | 0·00146 | 0·076 |
| 2. Dortmund Water-tube .. .. .. | Purified | 1·229 | 0·00138 | 0·00195 | 0·112 |
| 3. Ratingen ,, | Ordinary | 1·146 | 0·00155 | 0·00148 | 0·135 |
| 4. Kaiserslauten ,, | Purified | 1·442 | 0·00122 | 0·00193 | 0·085 |
| 6. Nürnberg ,, | Ordinary | 1·610 | 0·00246 | 0·00164 | 0·151 |

These results are given chiefly to confirm the general result shown in nearly all experiments, namely, that the amount of priming estimated from a salt test is an insignificant percentage.

*Comparison of the salt methods with other methods.*—It is clear that the general result obtained when the salt test has been used is that in ordinary cases there is very little moisture in the steam. Some trials made lately by Professors Kennedy and Unwin gave the same result. On the other hand, some trials simultaneously with the salt method and one of the other methods, such as the wire-drawing or separating method, have given this result: that the moisture in the steam indicated by the salt method was only about one-tenth as great as that shown by the other methods, and that not in steam taken from a steam pipe at a distance from the boiler, but in steam taken directly out of the boiler itself. It is clear that the salt test can only indicate boiler water mechanically mixed with the steam by ebullition, not moisture produced in other ways. It might be expected, therefore, that the salt method would give a larger dryness fraction than other methods. Whether the great difference is entirely attributable to this cause, or in part to inherent difficulties in the salt method, cannot at present be ascertained. It would rather seem that the Escher method, which apparently has never been tried, would give the best results, if used in a case where the trial extended over a week or more. A subordinate question is this. Some engineers have thought that the salt method was specially suitable for boiler trials because it gave directly what may be called the mechanical priming, although other methods were more suitable for engine trials where what is wanted is a knowledge of the absolute quality of the steam. This view seems to be founded on a misapprehension. In determining the efficiency of a boiler it is necessary to know how much of the feed leaves the boiler as steam and how much as water. If, in steam taken directly from the boiler, there is more moisture than corresponds to mechanical priming, that is as much a deduction from the evaporation of the boiler as if it were mechanical priming. The product of the boiler is so much wet steam, and the value of this steam depends on its dryness. The total heat utilised depends on the dryness. It is not at all important how the moisture came into the steam provided it is there. The only point to attend to in a boiler trial is that the steam tested should be taken directly from the boiler, and not from a steam pipe in which condensation due to radiation may have been going on. It is equally desirable that in an engine test the steam should be taken from the steam pipe very near to the engine.

(*To be continued.*)

---

# THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(***From our own Correspondent.***)

IRON and steel masters from this district who have returned from the Brussels meeting of the Iron and Steel Institute are greatly impressed with the progress which Belgium has made in iron and steel manufacture since the previous visit of the Institute twenty years ago. It is stated that the Belgians have gone ahead in a most remarkable fashion. They have adopted the basic process of steel making to a very considerable extent, with hydraulic power and so forth. In the opinion of some of our local ironmasters, the Belgian works are equally equipped in every respect to the North of England and other leading steel works in this country. The essential difference between English and Belgian works is in the matter of labour. A Belgian is engaged twelve hours a day, but his pay is much less than that given to the Englishman. At a good bar mill producing twenty tons per turn, the roller, it is stated, does not receive more than 5s. a day. In England the pay would be £1 a day. Belgian fitters toil twelve hours a day for 3s. 4d.

Disappointment is expressed by local ironmasters that under the new American Tariff Act hoops used for cotton baling purposes, and known in the English trade as cotton ties, although substantially reduced in duty as compared with that imposed under the old tariff, are still scheduled at a rate which is almost prohibitory—something like £5 a ton. The manufacture of these hoops for the United States, although a "season" trade, was for many years amongst one of the most profitable and important lines of the South Staffordshire industry. Further, it is asserted that the American iron and steel masters themselves are now selling these hoops delivered at the principal depôts in the cotton growing States cheaper than any such material can be bought in this country.

A careful review of the changes brought about by the new tariff shows that with few exceptions the tariff remains thoroughly protective. The average duties are still as high as those of European countries, which remain distinctively on the Protectionist platform. The duties, it is true, have been lowered in many instances, but are still sufficiently high to keep out most foreign competitors. At the same time, the changes that have been made are well in the right direction, and it is satisfactory to remember that McKinleyism cannot be restored for another three years, even should the Republicans control the next two Congresses.

It is gratifying to be able to report a continuance of the iron trade revival on the Birmingham and Wolverhampton Exchanges, to which I referred two weeks ago. Pig iron has now risen fully 1s. 6d. to 2s. per ton; and some makers are even asking an advance of 2s. to 2s. 6d. on Derbyshire, Lincoln, and similar makes. Steel and merchant iron has advanced 2s. 6d. per ton, and sheet iron 5s. The improvement is distinctly the result of the increased confidence engendered by the settlement of the American tariff question, and its continuance is expected.

An important meeting of the Coal Trade Wages Board was held on Wednesday to receive the accountants' return of the average selling prices of coal and slack during the months of May, June, and July last. The examination of the employers' books was ordered subsequent to the recent reduction of wages in the Federation districts. The accountants return the net price at 5s. 10·81d., and under the sliding scale the employers claimed that thick coal miners' wages should be reduced from 4s. 8d. to 4s. 2d. "per day or stint," and thin coal miners' wages from 3s. 8d. to 3s. 3½d. per day. The men's delegates expressed great surprise at the large diminution in prices shown, and complained of the employers underselling. They appealed to the owners not to enforce the full reduction, and after consultation the masters announced that without forming any precedent they would agree that thick coal wages should now stand at 4s. 4d., and thin coal wages at 3s. 5d.

The Oldbury Railway Carriage and Wagon Company has just received an order from the Nippon Railway Company, of Japan, for one hundred railway carriages. The order consists of eight first-class, sixteen second-class, and seventy-six third-class carriages. The gauge of the railway is 3ft. 6in., and the carriages are built on the English principle, with cross compartments, side-doors, and lantern roofs. They are 23ft. 3in. long, and 7ft. 3in. wide, the body, framing, and panelling being of teak highly varnished. The wheels are fixed, and each carriage is fitted with the vacuum automatic brake. The under frames are of pressed steel. The third-class carriages have five compartments, and are open above the seat backs from end to end. Each first-class carriage has two saloon compartments, with lavatory compartments between. Woven cane seats run along both sides and one end, and are provided with cushions and backs of buffalo hide. The interior panelling is of French polished sycamore, with bandings and mouldings of teak. The second-class carriages are similar to the first-class, excepting that the seats are upholstered with Vulcan leather cloth, and the interior is grained and varnished.

I regret to have to announce the death of Mr. John Roberts senior partner in the firm of Messrs. J. and S. Roberts, ironfounders and engineers, of West Bromwich, one of the oldest-established and best-known firms in this district. Mr. Roberts, who was seventy-seven years of age, died at his residence after an illness of eight weeks.

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester.*—The stronger tone which has recently been coming over the iron market is being well maintained. The hardening up in pig iron has been followed by a considerable weight of buying, and although merchants and consumers have followed the upward movement in pig iron very hesitatingly, makers have been able gradually to secure their advanced rates. The question just now asked is whether this spurt in buying will continue long enough to give a permanent lift to prices; it would not seem at present to be backed up by increased requirements for actual consumption, but to be due rather to consumers and merchants who have held back, being more anxious to contract, in the belief that prices have got to the lowest possible point, and that any further move must be upwards. It is of course quite possible that very shortly, when requirements have been satisfied, there will again be a lull in the market; but the fairly-large orders which makers have now got on their books, coupled with the generally extreme lowness of stocks, have so strengthened their position that there is little probability of prices getting back to the excessively low figures which were being taken a week or so back. The improvement—such as it is—has, however, not made itself appreciably felt beyond the pig iron trade. Finished ironmakers, although the increased cost of raw material has compelled them to take a firmer stand, with regard to manufactured iron are in no materially better position; and the steel trade, even with the continued stoppage of production in Scotland, remains in only a very unsatisfactory condition.

The Manchester Iron Exchange on Tuesday brought together about a fair average attendance, and a more hopeful tone prevailed generally throughout the market, with a further upward tendency in prices. Any real improvement is, however, still chiefly confined to pig iron, in which a considerable weight of business has been put through, and buyers have had to follow the advance reported last week. Lancashire makers, although they have not yet made any actual upward move upon their list rates, have been securing more business at their full prices, and are firm at 40s. for forge to 42s. for foundry, less 2½, at the works. Moderate sales of forge iron have been made on this basis where local makers have favourable rates of carriage in their competition with district brands, whilst in foundry qualities they have booked a moderate number of small orders in the Manchester district at prices equal to about 44s. 6d. delivered. The chief weight of buying has, however, been in what are still relatively low-priced district brands. Lincolnshire makers, who last week had booked a fair business at quite 6d. over their recent quotations, have since been able to secure a further advance of 6d., considerable transactions having been put through at about 39s. for forge, to 40s. for foundry, net cash, delivered Manchester, and as they are now in most cases fairly well sold, they are not quoting under 39s. 6d. to 40s. 6d. respectively for forge and foundry delivered here. Buyers have scarcely yet been got up to the maximum figures now being asked, but as makers are indifferent about selling, it would seem likely that any further orders which are placed will only be accepted at full rates. Derbyshire makers also continue to stiffen up in their prices, and most of them do not at all care about selling in any quantity, 45s. to 45s. 6d., net cash, being now about the minimum figures for foundry qualities delivered in the Manchester district. For good named foundry, Middlesbrough makers still quote 45s. net cash, delivered equal to Manchester, but this figure has not been got on any real weight of actual business. The very few holders of Scotch iron are scarcely quoting any actually definite prices, but it would be difficult to place orders for Eglinton under about 48s. and 48s. 6d. net prompt cash, delivered at the Lancashire ports.

In the finished iron trade there is still no really material improvement to report. An increased number of inquiries are, however, coming forward, and buyers show more disposition to place orders, but the actual business done is still only of comparatively small weight. Makers are, however, hardening in their prices, and although there is no really quotable advance, orders could not be placed on the same favourable terms as would have been accepted a week or two back, and there is a disinclination to sell at current rates, except for actual specifications, makers, in view of the upward movement in raw material, naturally showing no disposition to commit themselves to forward engagements. Delivered in the Manchester district, Lancashire and North Staffordshire bars are not quoted under £5 7s. 6d. to £5 10s.; Lancashire and Staffordshire sheets, £7 to £7 5s.; and Lancashire hoops, £5 17s. 6d. for random, and £6 2s. 6d. for special cut lengths. In the steel trade rather more business in some directions is reported, but the position generally remains without any real improvement. For ordinary foundry hematites 53s., less 2½, remains about the average figure, with steel billets still readily obtainable at about £4 net cash, and steel boiler plates £6 7s. 6d. to £6 10s. per ton.

In the metal market there has been a further upward move in list rates for manufactured goods, representing an all-round advance of ¼d. to ½d. per lb., and inquiries have been coming forward more freely during the last week. Delivered in the Manchester district, quoted list rates for manufactured goods are now as under:—Solid-drawn brass boiler tubes, 5¾d.; solid-drawn brass surface condenser tubes, 6¾d.; solid-drawn copper tubes, 7¼d.; patent red metal tubes, suitable for locomotive and marine boilers and condensers, 7d.; brazed copper gas and steam tubes, 6¼d.; brazed brass gas tube, 6d.; brass wire, 5¼d.; copper wire, 6¼d.; rolled brass, 5¼d.; yellow metal bolts, 4¾d. per lb.; cold rolled copper sheets, 54s. per cwt.; and copper bolts, £55 per ton.

The condition throughout the engineering industries remains much as reported for some time past. There is still no indication of any really increased weight of new work coming forward, and although here and there in exceptional cases more activity is reported, establishments generally continue only moderately off for work, and very few of them more than kept going from hand to mouth.

The prospects of the Manchester Ship Canal, although the improvement is very slow, are steadily moving in the right direction, and Mr. J. K. Bythell, the newly-appointed paid chairman of the company, was able to make a fairly satisfactory statement at the eighteenth ordinary meeting of the shareholders, held on Tuesday, in Manchester. In round figures 2,200,000 tons of traffic had been moved on the canal during the six months, and, although some people might be disappointed, he thought, considering all the difficulties in the way, they had made a very good beginning. With regard to the engineering portion of the work, satisfactory progress has been made in bringing the canal into full working order. The most important portion of the work has, of course, been the dredging of the waterway to get a full depth of 26ft. This work, which has been actively carried on, will, according to the report, soon be completed, and I understand that already there is practically a depth of from 25ft. to 26ft. in the Canal from end to end. The great difficulty in the way has been the enormous amount of sewage brought down into the Canal by the rivers Irwell and Mersey, which, in addition to materially increasing the amount of dredging to be done, has given rise to very serious complaints as to the unsanitary condition of the Canal, especially between Barton Locks and the Manchester and Salford Docks. With regard to the equipment of the Canal, the dock sheds that were in progress early on in the season have all been completed, and active operations are going on in the erection of the additional large three-storey sheds, of which full details have already been given in THE ENGINEER.

A 30-ton crane is now in operation, and twenty additional hydraulic cranes, which are being constructed, will shortly be ready for work. Operations will also soon be commenced for the construction of the jetty, outside the Eastham Locks, Parliamentary sanction for which has been secured, and tenders obtained for carrying out the work.

The coal trade, so far as local and inland demand is concerned, continues extremely quiet, but with the close of the month no further alteration is being made in the quoted prices. The leading Manchester colliery concerns, who have been forced by outside competition into various reductions during the past month, have now got down to the minimum figures, and at the district and Council meetings of the Lancashire Coal Sales Association it has been decided that no change shall be made in the official quoted rates. The better qualities of round coal still hang upon the market and accumulate in stock, whilst requirements for steam coals and engine fuel are just now being materially affected by the holiday stoppages in various manufacturing centres, which in most cases are being extended beyond the usual period. There is still some low-cutting in the open market to clear off stocks, but generally quoted rates remain at 11s. to 11s. 6d. for best Wigan Arley, 10s. to 10s. 6d. for Pemberton 4ft. and seconds Arley, 8s. to 8s. 6d. for common house-fire coals, 7s. to 7s. 6d. for steam and forge coals, with engine classes of fuel ranging from 3s. 9d. to 4s. 3d. for common sorts, to 4s. 9d. and 5s. 3d. for good medium qualities, and 6s. for some of the best descriptions.

In the shipping trade a fair amount of activity continues to be reported, chiefly in cargoes for Scotland, although some check has been given to buying during the past week, owing to anticipations of an early settlement of the Scotch strike. Prices remain about as last quoted, steam coal averaging about 8s. 9d. to 9s., and engine fuel, 5s. 6d. to 5s. 9d. per ton, delivered at the Garston Docks or the High Level, Liverpool.

It would seem not unlikely that the meeting of the Coal Trade Conciliation Board, which is being held to-day—Friday—in London, to consider an application made by the miners' representatives for a clear definition of the terms embodied in the resolution with reference to the 10 per cent. reduction in wages, may give rise to considerable contention with regard to the recent wages settlement. Some of the official leaders of the Miners' Federation express themselves strongly that, whilst the coalowners have been very keen in carrying into full effect the first clause of the agreement, with reference to taking off the last two advances of 5 per cent.—and in some cases, it is alleged, have gone even beyond the stipulated reduction—there has been rather a disposition to ignore the second clause with regard to the minimum rate of wage, and a strong case is being prepared for submission to the Conciliation Board, where the men complain that the coalowners are endeavouring to enforce reductions in wages to a greater extent than they are entitled to. The question of the day-wagemen, which has given rise to considerable trouble, is also to be brought forward; and the Board will be asked to include in the minimum wage agreement not only the miners, but all the underground workmen employed at the federated collieries.

*Barrow.*—Although during the past week there has been a very steady tone in the hematite pig iron market, makers have not done a large amount of business. On every hand the inquiry for iron continues to be poor. Consumers are only placing orders for iron just sufficient to cover their immediate want, and are content at that, having no disposition to go further and place for delivery at some future date. At some of the places on the coast the orders are almost worked out, but these makers are in a position to give immediate delivery, and are consequently booking some small orders. Others are engaged on orders booked some time ago. Taking the whole district through, the trade is being carried on very much on the hand-to-mouth principle. Prices are about the same, and makers are asking 44s. 6d. to 45s. 6d. per ton for mixed numbers of Bessemer iron, net f.o.b. In the warrant market holders are quoting 44s. 6d. per ton, and some iron has changed hands at that figure. The stores of warrants have been steady during the week, and still stand at 158,323 tons. Thirty-three furnaces are blowing, out of a total of seventy-six built.

Steel makers have nothing new to report. Business is very slack so far as new transactions are concerned, and in some of the mills the contracts are almost worked out. Taking all round there is a very limited business offering to makers. Rails are little sought after, and prices are a trifle easy. Shipbuilding material has been inquired after, but the demand is not by any means as good as it was a short time ago, mainly on account of the fact that shipbuilders are not booking any fresh orders. Tin-plate bars are a poor business, as also are hoops, and there is scarcely any request for the following:—Blooms, billets, slabs, or wire rods. Prices are nominally as follows:—Heavy rails, £3 15s.; light, £5 5s.; colliery, £5 10s.; ship-plates, £5 7s. 6d.; angles, £5 10s.; boiler plates, £6 per ton; tin bars, £3 17s. 6d.; blooms, £4; billets and slabs, £4 5s. each; wire rods, £6 12s. 6d. to £6 15s.; and hoops, £6 15s. per ton.

There is nothing new to note in the shipbuilding, engineering, and boiler-making trades. They are all fairly well employed, but no new orders are to hand.

Iron ore is in quiet demand. Average qualities are quoted still at 8s. 6d. to 9s. 6d. per ton net, at mines. East Coast coke is at 17s. per ton.

The export shipping trade is quiet. The returns show a decrease on last week's shipments. Up to date there is now a decrease of 11,000 tons.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

ALTHOUGH the output of the Barnsley district has been considerably lessened through two causes—the "play" caused by the feast holidays, and the lads' strike setting several collieries down—the stoppages have occasioned very little inconvenience, the supply quite equalling the demand. The boys, being subject to no trades union, play a free hand, and being usually easy to lead one way or the other, the trouble may break out in any district at any time. Most of the pits now working are waiting the action of the coalowners and miners' leaders in regard to the difficulty. A further conference took place on Friday at Sheffield. Mr. A. M. Chambers, President of the South Yorkshire Coalowners' Association, met representatives of the Miners' Association, including Mr. E. Cowey, President of the Yorkshire Miners' Association, and Messrs. J. Murray and W. Parrott. The conference, which lasted two hours, was conducted in private, and the result, which did not transpire, is expected to lead to an early settlement. It is urged, on behalf of the boys, that wages of less than 3s. a day shall not suffer any reduction, but to this the employers are opposed. Should an arrangement not be arrived at, the difficulty will be referred to the next meeting of the Conciliation Board. The employers have expressed their willingness to draw the line at all wages below 2s. 6d. a day. This compromise has been accepted by the Miners' Association, but the lads have still to be reckoned with.

In the meantime the house coal trade continues quiet, and little business is doing, buyers restricting their orders to immediate requirements. Hardly an average tonnage is being sent to London, and although coal is being despatched to Scotland, the weight is not heavy enough to exert any appreciable influence upon the bulk of the business. Concessions have been made in some instances to force sales, but coalowners generally stand out for current rates. For Silkstones, 9s. 6d. to 11s. per ton is still quoted; Barnsley house, 8s. 6d. to 10s. per ton; Flocktons, 8s. 6d. to 9s. 3d. per ton; inferior grades, from 8s. per ton. A fair demand, considering the advanced stage of the season, is still reported for steam coal, the Hull and other Humber ports taking a considerable tonnage from Yorkshire pits. Railway coal is being rather heavily delivered under contract, and prices remain steady generally. Barnsley hards make from 7s. 9d. to 8s. 6d. per ton; other qualities from 7s. per ton; gas coal in better demand at 7s. to 8s. per ton; manufacturing fuel is supplied largely in excess of demand, the market being very dull, and prices ranging from 3s. 6d. to 4s. 6d. per ton; smudge and small coal very weak and low-priced. Coke unchanged. A number of important coal contracts have been settled during the week, including the supplies for the Leeds Corporation Gas Works. These fresh contracts have, as a rule, been placed at last year's prices.

The improvement in the iron trade is certain to operate favourably on the steel industry. Although the prices of material are unsatisfactory, orders are obtained more readily, and, with the increased demand, a rise in quotations is only a question of a little time. The advance of 1s. per ton in hematites is a certain indication of better quotations ruling ere long. In crucible steel more activity is now reported, and the animation is certain to be increased as soon as the benefits of the lowered duties under the new American tariff begin to be experienced. The passing of that measure has promptly benefited the lighter staple trades. During the last week the exports from the Sheffield Consular District doubled in value. The improvement applied to all cutlery and steel products, as well as the wider range of goods taken by the United States markets. On the day following the acceptance of the modified tariff cablegrams were received in the city urging the immediate delivery of cutlery ordered some months ago. At present there is an exceptional rush to get on the market, and this, it is expected, will be followed by a steady trade. A leading steel manufacturer who was seen by the Correspondent of THE ENGINEER on Tuesday, stated that he was already very busy on American account, with every prospect of a sustained good trade throughout the year.

In well-informed circles here the belief is freely expressed that China will soon be in a position to operate heavily against Japan. Agents acting on behalf of China have arranged, and are arranging, for important supplies of military material, including quick-firing rifles, and these will, at an early date, be in the hands of the Chinese soldiers, who are singularly clever in effectively adopting new weapons when once the principals let their prejudices be broken down by the exigency of events. The Chinese are good soldiers when well led, and as there will be no lack of assistance in that direction, and abundant war material of a good type shortly in their country, the Chinese are expected to give a definite turn to hostilities ere long.

The leading East End establishments are busily employed upon the production of war material. The authorities do not seem greatly concerned over the new projectiles which have originated through the Russian process. Our local firms who have offered shells for experiment have not yet had the opportunity of having their productions officially tried, and it is now pretty certain that the Admiralty have no immediate idea of modifying the armour from the original specifications. No doubt, in the event of the projectile giving very startling results, provision will be made in future orders to meet the emergency. At present the work in hand for our Government is being proceeded with according to the terms of order received at the outset.

The tone in the iron market is decidedly more animated. This has been particularly pronounced during the last seven days. Consumers exhibit a general desire to cover their requirements in pig iron, instead of merely buying from hand to mouth, as has been the rule for a long time. This, of course, has led to the market being fairly buoyant, with a tendency to higher values. An increase of orders in the works of the iron and steel markets, if only to a moderate extent, would at once lead to an appreciable advance in quotations. At present values may be stated as follows:—Hematite, mixed numbers, 53s. 6d. to 54s. 6d., subject to discount and delivered at Sheffield; Lincolnshire forge numbers, 32s. 6d. to 33s.; No. 3 foundry, 34s.; Derbyshire forge, 34s. to 35s.; foundry, 38s., net at works. Bars, £5 5s. to £5 10s.; sheets, £7 to £7 10s.

Messrs. W. Jessop and Sons, Brightside Works, Sheffield, have just made some important additions to their plant for large marine work. Among the machinery newly laid down is a 69in. crank lathe with four rests and a 50ft. bed, constructed by Messrs. Hulse and Co., of Manchester. Another tool is a lathe with a 60ft. bed, intended for straight shafting and other plain work, constructed by Messrs. Smith, Beacock, and Tannett, of Leeds. This lathe is provided with four saddles and two fast headstocks, one with powerful treble gear, and in it either one long shaft or two shorter ones may be turned simultaneously. The firm have also added a horizontal boring and drilling machine, for various kinds of work. At the Brightside Works are at present being completed a number of shafts, large cast steel rudders, hydraulic cylinders, dredger and other castings and forgings for land and marine purposes, with shaft brackets for battleships, the latter including a set, making the third for the Spanish Government. Each of these brackets weighs 15 tons.

A further extension of the Yorkshire coalfield in the Doncaster district is contemplated. An agreement has been entered into for the working of the minerals on the Arksey-with-Bentley and Wheatley estate. The first hole borings have been made, and they confirm the opinion already expressed by geologists that the Doncaster coalfield is one of the most valuable in the country yet undeveloped.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE improvement in trade continues, and is not confined now to the raw material only, but has extended to other branches of the iron and allied industries, a feature which is considered satisfactory, and it justifies the opinion that the revival is brought about more by ordinary than by speculative influences. It is true that speculators have been very active during the last three weeks, but when it is remembered that they have for nearly two years fought shy of the iron market, because they did not see their way to invest their capital profitably, it is evident that they now take a more favourable view of the prospects. That better times are to be looked for is apparent from the improvement that is taking place in all the metal markets, and particularly in copper and lead, besides which the rise in silver is having a good influence. The shares of companies engaged in the iron and steel trades have also advanced in value, and it would appear to be the general belief that better times have commenced. Buyers are now anxious to purchase iron for autumn delivery, and it does not seem likely that they will do any better by waiting. It seems likely that the strike of Scotch miners will very shortly collapse, as the leaders are quarrelling, and some of the men are going back to work in spite of the picketting that is carried on. The Scotch coalmasters are proving themselves too much for the Federation, powerful though its leaders deem it to be. The strike has acted rather detrimentally to the trade of this district, where it was expected to lead to greater activity. It was thought that a good deal more Cleveland iron than usual would be consumed in Scotland because of the almost total stoppage of the Scotch blast furnaces, but on the contrary less has been taken, as the cessation of operations at the Scotch mills and forges and foundries has been more complete than was looked for, as fuel was obtained with such difficulty. When, however, the Scotch strike is over there will be a brisk demand for Cleveland pig from across the Border, because the consumers of pig iron will be able to start their operations at once, while it will be some time before the Scotch furnaces will be in a position to furnish adequate supplies of iron. This strike in Scotland accounts for the poor shipments of pig iron that are reported from the Tees this month. The exports to the Continent are quite as good as are usual in August, but to Grangemouth they have been very quiet, and the result is, that the August exports are smaller than those of almost any month this year, and they fall short of those of the corresponding month last year. This month they have reached 70,907 tons, as compared with 79,441 tons in July, 1894, and 82,183 tons in August, 1893, all to 29th. This decrease, coupled with a smaller local consumption, owing to the holidays at the mills, forges, and foundries on Tees-side last week, lead to the inference that stocks of Cleveland pig iron will this month show an increase of at least 10,000 tons; and thus in June, July, and August, months when substantial decreases in stock are usually looked for, there will have been rather heavy increases—and this notwithstanding that the make has been reduced this month by the stoppage of the furnaces for the blast furnacemen's holiday on the 11th. Connal's stock of Cleveland pig iron has declined; because No. 3 in makers' hands has been so scarce for prompt delivery that people have had to draw upon the quantity in the public stores, and on Wednesday night Messrs. Connal and Co. held 90,570 tons, or 4822 tons decrease this month.

The better prices for pig iron are being maintained, and orders have been booked freely for No. 3 from merchants and consumers at 36s. 3d. per ton for prompt f.o.b. delivery, while 36s. 6d. is now the general figure of producers. Early in the week some small lots were sold by merchants at 36s. 1½d., but nothing less than 36s. 3d. is now thought of, and the fluctuations in warrants have little influence upon the general market. No. 4 Cleveland foundry pig has been realising 35s. and gray forge pig has been raised to 34s. 3d. The hematite pig iron market is yet in a rather indifferent condition, and has not felt the improvement that has appeared in Cleveland pig. There have been sales of mixed numbers of East Coast hematite pig this week at 42s. 9d., and the quotation is now 43s.

Unfortunately, the efforts that have been made to bring about a settlement of the moulders' dispute have not been attended with success, and the strike, which has now lasted twenty-four weeks, appears to be as far off a termination as ever. Both the masters and men are agreed upon the question of settling the difficulty by arbitration, but cannot agree upon the basis to be arbitrated upon. The men insist that the arbitrators shall be called upon to adjudicate upon the claim made by the men for an advance of 2s. in time wages and 5 per cent. on piece prices, and that only. This was the question originally in dispute, but the employers have since made a claim for a reduction of wages, and they hold that this claim should be submitted to the arbitrators as well. On Monday there was a conference at Newcastle between the masters and the delegates of the men, when the former submitted the two following proposals, either of which they would accept as a settlement:—(1) That three expert referees be appointed with full power, to whom the matter below in dispute between the parties be submitted, and whose decision shall be binding on both employers and employed, viz.:—Whether, considering the state of trade, the moulders are justified in asking for an advance of wages, or whether the employers are justified in asking for a reduction of wages. The Court to decide whether there shall be any change either way, and if so, how much. (2) Should the contracting parties be unable to agree upon three expert referees, then each party shall appoint their own expert referee, and these two shall select an arbitrator, who shall be either a barrister or a County Court judge. The alternative proposal was that a truce be declared for six months, the employers agreeing that the wages of no trade will be interfered with during that time. These reasonable proposals the men reject, for they want the claim of the employers ignored altogether. It is greatly to be regretted, for the sake of the thousands who are thrown out of work through the action of these moulders, that this week's negotiations have proved abortive.

Some branches of the finished iron and steel trades exhibit an improvement, the demand being larger, and prices better. They all speak more hopefully of the prospects, and it is probable that the works of Messrs. Dorman, Long, and Co., at Middlesbrough, will shortly be reopened, and set fully in operation again. During the stoppage they are putting down a considerable amount of new plant. The new works of the Bedson Steel Wire Company at Middlesbrough, which have been in course of construction for over eighteen months, are to be opened next month, and will consume a considerable quantity of steel billets. At these works electricity will be extensively used as a motive power for small machines.

At the finished ironworks in the North of England the question of the shortening of the hours of labour is being taken up by the men, and at a meeting of delegates held at Darlington on Saturday it was resolved, "That this meeting of delegates, representing the works connected with and outside the Board of Conciliation and Arbitration, is prepared to advise the workmen to make the following offer to the employers:—That in all mills the charging shall be so arranged that no mill shall stop before one o'clock or continue working after two o'clock on Saturdays, except in cases of accident over which neither employers nor workmen have control, as no man would desire to leave heats in the furnace." The whole of the men will have to vote upon this before it is submitted to the employers.

The members of the Newcastle and District Association of Foremen Engineers and Draughtsmen, and also those of the kindred association in the Middlesbrough district, visited the North-road Locomotive Works of the North-Eastern Railway on Saturday, by invitation of Mr. Worsdell, locomotive superintendent of the line. Locomotives in all stages of construction were seen, and particular attention was called to two which had just been completed—a passenger express engine, and a new bogey passenger tank engine, a type of twenty to be built by the company. The latter is fitted with a new steam sanding apparatus.

The coal trade is brisk, and sellers are securing good prices for their produce. The increased activity is due partly to the larger requirements of Scotland, and if the Scotch miners' strike collapses these will drop off. At present a large tonnage of steam, gas, and manufacturing fuel is forwarded both by sea and rail. Coke is also in good request, and the price is well maintained.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE pig iron market has been scarcely so firm this week. The upward movement in prices has been arrested, and the amount of business doing is also smaller than last week. Business was done in Scotch warrants from 43s. 5d. to 43s. 3½d. cash. Cleveland iron is comparatively neglected, and there is scarcely anything doing in hematite warrants.

The prices of makers' iron are as follow:—G.M.B. f.o.b. at Glasgow, No. 1, 45s. per ton; No. 3, 43s. 6d.; Carnbroe, No. 1, 47s.; No. 3, 46s.; Monkland, No. 1, 48s.; No. 3, 43s. 6d.; Summerlee, No. 1, 56s.; No. 3, 50s.; Calder, No. 1, 58s.; No. 3, 50s.; Coltness, No. 1, 59s.; No. 3, 52s. 6d.; Glengarnock at Ardrossan, No. 1, 56s.; No. 3, 50s.; Eglinton, No. 1. 54s.; No. 3, 47s; Dalmellington at Ayr, No. 1, 50s.; No. 3, 47s. 6d.; Shotts at Leith, No. 1, 56s. 6d.; No. 3, 50s. 6d.

The shipments of pig iron from Scottish ports in the past week amounted to 4213 tons, compared with 6230 in the corresponding week. Holland took 1125 tons; Italy, 400; Canada, 410; South America, 20; India, 160; Australia, 310; France, 10; Germany, 240; Belgium, 20; Spain and Portugal, 140; China and Japan, 137; other countries, 115; coastwise, 1126, against 3451 tons in the same week last year.

There is no change in the number of furnaces in blast, which is six, compared with forty-six this time last year. Makers and consumers alike are holding their hands at present, and there is no likelihood of work being resumed until the miners return to the collieries.

The utmost stagnation prevails in the finished iron and steel trades. Merchants are doing a little, but it consists only of meeting the more clamorous wants of the trade. The works are all closed, and the gatherings on 'Change are productive of very little business.

The export trade in iron and steel manufactures is poor. In many cases makers of machinery are doing scarcely anything, and the exports of finished iron and steel are reduced to a minimum. The week's shipments from Glasgow embraced sewing machines worth £360, other machinery £10,140, steel goods £2625, and miscellaneous iron goods £11,000.

There is very little doing in Scotch coals. The entire shipments in the past week amounted to only 6330 tons, compared with 165,111 in the corresponding week of last year. One half of the entire shipments went from Leith to Grangemouth. Glasgow only shipped 639 tons, whereas the clearance of the same week last year was 51,000 tons. The total coal shipments for the year to date show a decrease of about 740,000 tons. On the other hand, fair quantities of coals are being received from England. It is estimated that the arrivals in the past week would amount to close on 50,000 tons. Prices are moderate, and the demand is slow.

The miners have been asked to vote this week on the question whether they will still adhere to the demand for an increase of 1s. per day, or accept 6d. with a guaranteed minimum wage for two years. The latter is the proposal of the English Federation, and has been received with a good deal of favour. It is not expected, however, that the coalmasters will agree either to the one proposal or the other. The view they take is, that the miners' demand was thoroughly unreasonable from the first. It was impossible for the masters to give the advance ten weeks ago, and their circumstances are not better but worse now.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

LABOUR agitators never seem to profit by past experience, and the old absurdity of creating a rupture when there is a lull in trade and a declining market is being repeated amongst the seamen at Newport and Cardiff. Mr. J. H. Wilson, M.P., has issued a notice on behalf of the Sailors and Firemen's Union, "That the rate of wages to be paid henceforth should be as follows: Steamers, sailors £4 per month, firemen £4 5s., cooks, stewards, boatswains, and carpenters in proportion; sailing ships, seamen £3 2s. 6d. Sailors and firemen arriving in port under these wages are requested to immediately give in their notices, and at once to report themselves to the Wages Committee."

Demonstrations, addresses by Mr. Wilson and others, have been the feature of the week, and I have heard of cases of ships being "blocked." Shipowners generally ridicule the whole thing, and say that Mr. Wilson could not have selected a worse time. Mr. John Cory is reported to have said "that he would willingly let him have half a-dozen of his ships for the Black Sea: that he should take all the profit, and he would make him a present of £50 into the bargain." "It is simply childish," he added, "to strike at such a time. It is not a question of profit now but of clearing expenses." Numbers of boats are being laid up on account of the slackness of trade, and one day last week five large steamers were pointed out to me lying idly in the mud waiting for custom.

Three steamers were blocked at Newport, Mon., up to Tuesday mid-day, when the full rate of wages demanded was paid, and the men signed on. At Barry some instances also of concessions to the seamen have occurred, but at Swansea there is no agitation up to the present. Whether the strike will extend there or not is uncertain, as it is stated that better wages are paid there than at Cardiff. It is thought that in some cases the agitators may succeed in getting their demand; but in the face of slack times, and with a lessening demand for steam and house coal, the majority of shipowners will prefer to put up their steamers and sailers, and the recoil upon the seamen will be a serious one.

Grave fears are entertained that trouble is looming in the Welsh coal trade. A hundred men of the Ferndale Collieries are out in consequence of some dispute, and it was reported midweek that the mass of the collieries of Ferndale are in sympathy. Overtures have been made by the management, but have not yet been accepted, and a mass meeting has been called. The men contend that a distinct breach of the sliding scale has been attempted If the belief of alarmists, and even of "Mabon," were accepted, we are threatened with another attempt to destroy the sliding scale; but I have greater faith in the good sense of the mass of the colliers than to think them capable of so foolish an act.

Troubles are attending North-Welsh collieries, and at one of the largest, Bettisfield, a strike has taken place for a 10 per cent. advance.

An important meeting of the Cambrian Miners' Association was held on Monday, when the question was discussed as to the best means to release the surplus moneys belonging to the various relief funds throughout the country, for the purpose of forming a central fund, with a view of relieving all sufferers from mining accidents. Mr. Abraham, M.P.—"Mabon"—who was present, suggested that a Bill should be passed through Parliament, and this view was adopted.

With such an excellent organisation existing as the Miners' Fund, with all "machinery" in capital working order, the course evidently should be to make it the receptacle of all funds, and thus avoid the expenses of another institution.

If quietness prevails on 'Change in respect of the coal trade, there is a certain degree of briskness this week in collieries, and new undertakings are being pushed ahead well. The sinking in both of the Aber pits is going on well; and at the Dowlais Colliery, now that the water has been grappled with, sinking is pushed on vigorously. The pumping machinery is of great power, so there is no fault to be found, or the management accused of neglecting the dearly bought experiences of the neighbouring colliery of Penrhiwkiber. I am glad to see, however, that at length a turn in the tide is visible, and the yield to investors is close upon 10 per cent.

Powell's Duffryn coal, which one sees in evidence at Newport, Mon., at the Bute, and at Barry, will shortly have accessions. Two pits are being sunk below Bargoed, and all the pits in the Rhymney Valley are doing full time.

I noticed an unusually large number of laden Rhymney Ironworks wagons on Saturday last at Cardiff, a good indication of Mr. W. Smith's activity.

The Campagna, with Lewis Merthyr steam coal, has beaten the record. The Lewis Merthyr, formerly known as the Coedcae, has an able manager in Mr. Richards. Mr. W. Rees is the mining engineer.

Good work is reported of the new sinking of Mr. Christmas Evans, of the Dinas Main Collieries, who is sinking to the deep.

At Swansea the coal trade is brisk, and also at Newport, Mon., where of late the tonnage coming in has been very large, and handled with an efficiency which would have won hearty encomiums from the late Sir George Elliot.

At Swansea some concern is felt at a mischievous rumour circulated, that owing to a blunder in the draughting of the coal clause of the American tariff, the imports of anthracite coal are forbidden. If true, this would be a serious blow in the face of a steady export from Swansea of this class of coal to the United States. Swansea coal shipments last week were close upon 40,000 tons; in patent fuel business was not so brisk.

On 'Change, Cardiff, this week, coal prices were much about the same as they were last week, and were better than on Saturday. Best qualities steam were quoted from 11s. 3d. to 11s. 6d.; seconds, from 10s. 9d. to 11s.; best Monmouthshire, 10s. to 10s. 6d.; small, 5s. 6d. to 6s. f.o.b. On house coal the influence of improving weather, after nearly six weeks rainy and stormy weather, was shown perceptibly. Latest quotations are:—Best households, 11s.; seconds, 10s. to 10s. 6d.; No. 3 Rhondda, 10s. 6d. to 10s. 9d.; brush, 8s. 6d. to 8s. 9d.; small, 6s. 6d.; No. 2 Rhondda, 8s. 6d. to 9s.; through, 7s. to 7s. 3d.; small, 5s. Coke is in moderate demand. Cardiff prices:—15s. to 16s. for furnace; foundry, 17s. to 20s. 6d., according to brand. Pitwood is in good demand, 15s. 9d. ex-ship. Iron ore dull, from 9s. 6d. to 9s. 9d. Porman, and 11s. to 11s. 3d. Rubio.

Iron and steel exhibit a trifle more vitality. Ebbw Vale is busy with bar, rails, and sleepers, Blaenavon moderately well occupied, and at Cyfarthfa and Dowlais a fair average make of steel bar is being turned out. I noticed last week that the Dowlais consignment of bars on the Taff showed an increase. "Parcels" of rails are on the increase; a cargo went to Demerara this week, and a consignment to Highbridge. Brown and Lennox, at Pontypridd, are busy, and the various foundries are moderately brisk. Competition keen. Swansea quotations this week are as follows:—Glasgow warrants, 43s. 5d.; Middlesbrough No. 3, 36s. 4½d. prompt; Welsh bars, £5 to £5 2s. 6d.; angles at usual extras. Sheet iron, £6 to £6 10s. f.o.t. at works; steel, £6 5s. to £6 10s., with the usual extras for higher gauges. Bessemer steel tin-plate bars, £4 2s. 6d. to £4 5s.; Siemens best, £4 5s. to £4 7s. 6d. Steel rails, heavy, £3 17s. 6d. to £4; light, £4 10s. to £4 12s. 6d. f.o.t.; sleepers, angles, channels, &c., according to specification.

A cablegram has been received from America notifying that the Tariff has become law, and increased animation is fully expected in tin-plate. Increased business has set in already, and prices show a little advance, at present confined to a few pence. Makers are holding on and refuse to sell forward. Last prices are:—Bessemer cokes, 10s. 6d. to 10s. 9d.; Siemens, 10s. 9d. to 11s.; ternes, per double box, 28 by 20 c., 20s., 21s., 22s., to 24s.; best charcoal, 12s. to 12s. 6d., according to finish; wasters, 6d. to 1s. per box less than primes; odd sizes usual extras. All delivered in Prince of Wales' Dock, Swansea, cash, less 3 and 1 per cent.

Anthracite is from 8s. 6d. to 12s. 6d., according to quality. Block tin, £71 12s. 6d. to £71 17s. 6d. Patent fuel, 10s. 6d. to 11s.

Present state of tin-plates, Swansea, 303,871 boxes.

I much regret to announce the death of Mr. Brewer, Chief Engineer on the Taff Vale Railway. Mr. Brewer's father was locomotive engineer to the late Crawshay Bailey, who was one of the pioneers in the introduction of locomotives into Monmouthshire. Mr. Brewer was a pupil and afterwards assistant to Mr. Williams, the late Taff engineer, and at his death succeeded him. No one had a more accurate knowledge of the specialities of the line than he, or made a more efficient witness on Parliamentary Bills. He was only in his fifty-second year.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THERE has been very little alteration in the iron trade of late, both the raw and the finished iron department being but quietly engaged, while prices continue very low. For the present there is a general hesitation about placing orders, and it is not safe to make any predictions, but the expectation is that autumn business will be fairly good. The Silesian iron market maintains a quiet tone. Pig iron continues in weak request, and the different sorts of malleable iron are also but slowly inquired for; indeed, manufacturers will find it very difficult to keep their concerns going regularly unless further contracts can be secured. The steel works as well as the iron foundries remain in rather a poor condition. Export of iron and iron manufactured goods to Russia has considerably decreased of late.

Demand and inquiry continue to be fairly good on the Austro-Hungarian iron market, and a regular activity is maintained at the works. Bars as well as plates meet with a lively request, while the inquiry for girders shows a slight decrease. Stocks are not large, and the works in many cases stipulate rather long terms of delivery. The business in rails and railway requirements continues extremely unfavourable. Export trade is limited, while the demand on local account has been fairly satisfactory.

The reports that are given of the French iron business may be considered as rather favourable, though orders of importance have not been received for many weeks past, but there is a sufficient amount of work secured to keep the mills quietly but regularly engaged. Changes in quotations have not taken place lately.

Belgian iron business drags on in a lifeless fashion. Here and there an improvement in demand has been perceptible, girders in steel, for instance, and plates being in lively request, but, taking it all through, the tone of the market is decidedly weak. Export in iron or steel has been uncommonly dull of late, only for girders and wire a few orders have been placed. List quotations for July and August of present year show no changes whatever. Up to date Luxemburg foundry pig is quoted 48f. p.t.; forge pig, 46f. p.t.; merchant bars, f.o.b. Antwerp, No. 1, 110f. p.t.; No. 2, 115f.; No. 3, 120f. p.t.; free Belgian station, No. 1, 112·50; No. 2, 117·50; No. 3, 122·50 p.t.; girders, f.o.b. Antwerp, 107·50 to 110f. p.t.; iron plates for export, No. 2, 125f., No. 3, 145f. p.t.; steel plates, 142f. p.t.; steel rails, 95f. p.t. Of the forty-two existing blast furnaces twenty-nine only were in blow at the end of July, of which fourteen produced 1220 t. forge pig, three produced 235 t. foundry pig, while twelve yielded 1150 t. basic per day. The following shows production of pig iron in July and during the first seven months of present year:—

| | July. | | 1st January to 1st August. | |
|---|---|---|---|---|
| | 1894. | 1893. | 1894. | 1893. |
| | t. | t. | t. | t. |
| Forge pig .. .. .. | 36,000 | 31,920 | 225,820 | 243,590 |
| Foundry pig .. .. | 7050 | 6821 | 54,465 | 46,641 |
| Basic .. .. .. .. | 34,500 | 22,010 | 241,650 | 149,635 |
| Totals .. .. .. .. | 78,150 | 60,751 | 521,935 | 439,866 |

Affairs on the Rhenish-Westphalian iron market continue very much as last reported. Buyers are still extremely careful about placing orders, and only cover their immediate requirements, while producers, on the other hand, do not care to sell at the reduced prices that are offered them. The Siegerland Works have considerably limited their output lately, and quotations have become a trifle more firm. Compared to last week, the demand for spiegeleisen as well as for forge pig and basic has somewhat improved. There is little to note in the malleable iron business, except that the bar trade has been a trifle less lively than before, but a sufficient amount of orders has been secured previously, and so the works can be kept going quite regularly; prices exhibit pretty much firmness generally. Girders are in moderate request at weak quotations. The situation of the hoop trade continues favourable, demand being brisk and prices firm. The plate and sheet trade is pretty active, and there is a good employment maintained at most of the foundries. All sorts of wire and wire nails are languid. The total production of pig iron in Germany, including Luxemburg, was for July of present year 476,894 t., of which 145,132 t. were forge, pig, and spiegeleisen, 41,726 t. Bessemer, 209,283 t. basic, and 80,753 t. foundry pig. Production in July, 1893, amounted to 413,771 t., in June, 1894, it was 471,922 t. From January 1st to 31st of July, 1894, no less than 3,125,965 t. were produced, against 2,815,731 t. for the same period the year before.

German import in iron was, for first two quarters of present year, as under:—

| | 1894. | 1893. | 1892. |
|---|---|---|---|
| | t. | t. | t. |
| Pig iron<br>Scrap iron .. .. .. .. .. | 122,414 | 80,233 | 90,495 |
| Rails .. .. .. .. .. .. .. | 56,797 | 44,965 | 56,616 |
| Wire .. .. .. .. .. .. .. | 102,307 | 91,747 | 95,372 |
| Plates .. .. .. .. .. .. .. | 41,731 | 32,314 | 30,469 |
| Hardware .. .. .. .. .. .. | 142,292 | 116,919 | 96,561 |
| Fish-plates and sleepers .. .. | 19,143 | 17,251 | 16,645 |

Export to Russia was

| In June. | | During first two quarters. | |
|---|---|---|---|
| 1894. | 1893. | 1894. | 1893. |
| t. | t. | t. | t. |
| 16,755 | 8887 | 60,335 | 42,631 |

During the first quarter of the present year 6692 t. iron were sent to Russia, in April export amounted to 17,076 t., in May it rose on 19,072 t., and in June it was 16,755 t. The amount of rails sent to Russia was, for the first two quarters of 1894, 3342 t.; for 1893 it was 173 t. only; and for the same period in 1892 it was 498 t. German trade in coal was in tons as under:—

| | 1894. | 1893. | 1892. |
|---|---|---|---|
| | t. | t. | t. |
| Import in June .. .. .. | 420,241 | 431,955 | 361,937 |
| During first two quarters .. | 2,147,780 | 2,205,210 | 1,610,059 |
| Export in June .. .. .. | 706,786 | 678,491 | 670,305 |
| During first two quarters .. | 4,301,491 | 4,281,291 | 3,997,571 |

## AMERICAN NOTES.

(*From our own Correspondent.*)

New York, August 23rd.

Dealers in iron, steel and railway equipments and supplies are living in anticipation of large orders from railway corporations during the next two months. The subject of better equipment is now being considered by boards of several systems, under the strong recommendation of the engineering management. It is pointed out that less money has been expended in repairs, equipments and betterments during the past year than for any of many years past, that both cars, engines and machinery for repair shops are needed, and that a general improvement ought to be made when supplies can be had on such reasonable terms. The voters of this city will vote for or against a scheme to build an underground rapid transit system, which it is estimated may cost 50,000,000 dols. Agitations are being started in the State looking to the construction of 500 miles of ship canal connecting Albany with Lake Erie, and also with the St. Lawrence opposite Montreal. The objective point is to divert to New York more or less traffic of the North-west, which now passes down the St. Lawrence. Other important engineering enterprises are under consideration, but enterprise must await more inviting financial conditions.

## RECONSTRUCTION OF A BRIDGE OVER THE SEINE.[*]

By R. Audra.

The railway crosses the Seine no less than five times between Garenne-Bezons and Rouen. The bridges were originally of timber, but about thirty-five years ago they were reconstructed with cast iron arches. One of them was destroyed in the war of 1870, and afterwards rebuilt with straight girders. The others have been a source of anxiety almost ever since their construction, and particularly of late years with the increase in rolling loads; the spandrils have cracked in many places, the cause of which is assigned to the torsional stresses arising from the transverse bracing between different ribs.

A careful study of the structures has led to the decision to rebuild the whole series of arched bridges, and the present article describes the reconstruction of the first, recently opened for traffic. It is called the "Pont du Manoir." The first idea was to replace the cast iron arches by wrought iron arches, but the condition of the foundations was such that it was considered dangerous to disturb the condition of loading of the piers to the extent which such an operation would have involved. The next solution was to replace the arches by girders on the same piers, and to reconstruct each bridge in halves, so as to have always one line of rails available for the traffic. It was found, however, that this plan would require six years for completion, even if more than one of the bridges was taken in hand at the same time. It was considered inadmissible to hamper the business of the railway for so long a period, and another plan was considered, viz., that of making a temporary bridge, so designed as to serve for each structure in turn during reconstruction. This was found to be more costly than building new bridges altogether, and, after certain difficulties about deviating the line had been overcome, the plan of making entirely new bridges was decided on.

At the "Pont du Manoir" the old bridge was in six spans, while the new one is in three spans, with a total width between abutments of 668ft. The foundations were laid by compressed air on a chalk foundation, the greatest depth below low water in the river being 42ft. The girders are double-webbed lattice girders 26ft. 3in. deep, 29ft. 6in. apart between centres. The cross girders are 3ft. 3in. deep and 14ft. 7in. apart, with trimmers carrying a floor of $\frac{5}{16}$in. flat plates. The cross girders are attached to the lower boom, and the main girders braced overhead. The girders are continuous over the piers, and were erected by launching out from the abutments. The stresses during erection by this method were greater than they will be in use under the greatest rolling load. The bridge cost £80,100, independently of deviations, &c., and of the demolition of the old bridge.

Launch of a New Liner.—Messrs. F. Schichau and Co., of Elbing and Dantsic, recently launched from their yard in Dantsic the Prinz Heinrich, a steel twin-screw steamer of 6600 tons register, built to the order of the North German Lloyd for the company's mail service to China and Australia. Her dimensions are:—Length over all 454ft. breadth 51ft., depth 33ft. She will have accommodation for about 80 first-class, 80 second-class, and 1000 third-class passengers. The vessel is specially arranged for service in the tropics, the first-class cabins being all on the upper deck. The second-class accommodation is on the poop, and the third-class on the main deck. The promenade deck is 200ft. in length, and has a permanent wooden awning, on the top of which are placed the lifeboats. The steamer is driven by two sets of triple-expansion engines, indicating each 2500-horse power, of a new type first introduced by Messrs. Schichau two years ago on the Austrian ironclad Tegetthoff. The *Times* says the naming was performed on behalf of Prince Henry—after whom the vessel is named—by the commandant of Dantsic, Lieutenant-Colonel Mackenzen, with the Emperor's consent. The Prinz Heinrich is a sister ship to the Prinz Regent Luitpold, which has lately made her trial trip at Dantsic, obtaining a speed of 15½ knots. These two twin-screw steamers are the first large ocean steamers built by Messrs. Schichau, who have hitherto built only fast torpedo vessels and men-of-war. The ships of the North German Lloyd are for the most part British built, but the Prinz Heinrich and Prinz Regent Luitpold, being intended for the mail service to China and Australia, for which the company receive a subsidy from the Imperial Government, had to be built in Germany under Government supervision, in accordance with the terms of the mail contract.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

15*th August*, 1894.

15,548. Line-throwing Guns, R. Deane, London.

15,549. Machines for Washing and Drying, F. Vinten, London.

15,550. Cycle, C. A. Briner, London.

15,551. Securing the Doors of Lifts, Z. A. R. Nesbit, London.

15,552. Making Cigarettes, C. V. A. A. de V. Beauclerk and W. Brodrick-Cloete, London.

15,553. Velocipedes, A. H. L. Grivel, London.

15,554. Elastic Tires for Cycles, E. Gérard and A. Picon, London.

15,555. Universal "Tel," J. Forrester, London.

15,556. Shears, C. Smith.—(*E. Smith, New Zealand.*)

15,557. Shades for Lamps, A. H. Weston, London.

15,558. Preservation of Perishable Substances, D. A. Sutherland, London.

15,559. Photographing Circular Surfaces, A. H. Smith, London.

15,560. Motive-power Engines, Sir E. F. Piers, London.

15,561. Manufacture of Cartridge Cases, R. D. Sanders, London.

15,562. Fire-grates for Furnaces, H. J. Piron, London.

15,563. Sheet-metal Pulleys, O. W. Ketchum, London.

15,564. Manufacture of Azo-dyes, J. Y. Johnson.—(*The Badische Anilin and Soda Fabrik, Germany.*)

15,565. Motor for obtaining Motor Force, L., E., J., and A. Guilbaud, London.

16*th August*, 1894.

15,566. Mowing Machines, P. Pierce, Wexford.

15,567. Testing Roller Mill, A. Steiger, London.

15,568. Fastening Knife Blades in Handles, G. E. Malcham and T. S. Yeomans, Sheffield.

15,569. Stands for Supporting Cycles, T. P. Davies, Manchester.

15,570. Needle Threader, T. W. Johnson, Redditch.

15,571. Applying Pressure to the Rollers of Wringing Machines, R. Varley and J. P. Wolfenden, Keighley.

15,572. Tea Infuser, E. Delarne, Birmingham.

15,573 Storage of Electric Force, J. T. Cathcart, Newburgh.

15,574. Corsets, C. Rubens, London.

15,575. Gasaliers, C. Smith, Birmingham.

15,576. Fluid Metres, H. H. Frost, Manchester.

15,577. Toys, H. P. Lavender, Walsall.

15,578. Horseshoes, J. Sutherland and J. Anderson, Glasgow.

15,579. Lever Motion for Window Blinds, R. Halliwell and J. Lawton, Oldham.

15,580. Mud Guard for Vehicles, R. Ferguson, Glasgow.

15,581. Hair-pins, J. T. Gray, Glasgow.

15,582. Pantographic Engraving Machines, T. Nixon, Glasgow.

15,583. Knitting-machines, R. Wallwork, Manchester.

15,584. A Recess in Flat Nails, H. E. Holloway, Wolverhampton.

15,585. Apparatus for Condensing Smoke, E. Davies, London.

15,586. Machinery for Drying Spent Hops, E. Davies, London.

15,587. Propelling Cycles, G. Pirnie, Dundee.

15,588. Adjustable Beds for Invalids, T. Turner, Ketton.

15,589. Plastering for Ceilings, F. H. Jung, Salisbury.

15,590. Machinery Belting, H. N. Brent and F. Marsh, South Weald.

15,591. Machinery for Preparing Tobacco, R. A. Sloan and J. E. L. Barnes, Liverpool.

15,592. Cycles, H. W. Ashby, Dublin.

15,593. Manufacture of Waterproof Material, J. A. Turner, Manchester.

15,594. Corset, M. Wutow, Manchester.

15,595. Fly Trap, J. Thornhill, Gainsborough.

15,596. Combined Match-box and Windguard, A. E. Parsonage, London.

15,597. The Kimberlead, J. M. Kimber, London.

15,598. Shelves for Holding Books, &c., A. W. Lambert, London.

15,599. Air Hub and Valve for Cycles, J. R. Rickard, London.

15,600. Electrically Heated Curling-tongs, O. March and A. Winterbottom, London.

15,601. Forcing Liquids from Casks, L. and F. Kohout, London.

15,602. Combination Gun and Pistol, M. W. Fairbanks, London.

15 603. Driving-gear for Cycles, S. C. Eisenhart, London.

15,604. Apparatus for Washing Metallic Ores, C., W., and G. K. Craig, London.

15,605. Life-saving Raft, F. Foord, London.

15,606. Heating Apparatus, A. J. Boult.—(*P. R. Horn, Germany.*)

15,607. Manufacture of Glass, R. C. Baker, Liverpool.

15,608. Spittoons, G. C. Dymond.—(*C. Wellhöfer, Germany.*)

15,609. Cover for Coal-cellars, W. Moore, Manchester.

15,610. Surgical Bandages, G. C. Dymond.—(*The Firm of Kahnemann and Krause, Austria.*)

15,611. Envelope and Bag Machines, G. R. Clarke, Liverpool.

15,612. Heating Apparatus, A. J. Boult.—(*P. R. Horn, Germany.*)

15,613. Frames of Umbrellas, S. Learoyd, London.

15,614. Signalling Apparatus, P. S. Pilcher, London.

15,615. Spikes, C. K. Welch and J. J. Hadley, London.

15,616. Water Gauges, W. Stricker and K. von Koeppel, London.

15,617. Registering Telephonic Conversations, A. Münch, London.

15,618. Fire-escapes, J. C. Merryweather and C. J. W. Jakeman, London.

15,619. Apparatus for Closing the End of Torpedo Tubes, G. J. Carter, London.

15,620. Burning Refuse, R. A. Chesebrough, London.

15,621. Manufacture of Dye-stuffs, H. E. Newton.—(*The Farbenfabriken vormals Friedrich Bayer and Co., Germany.*)

15,622. Lubricators, F. Jaeger, London.

15,623. Golf-clubs, H. H. Cordes, London.

15,624 Safety Attachment for Hat-pins, H. H. Cordes, London.

15,625. Book Holder, J. Sanderson, London.

15,626. Miners' Safety-lamps, T. Thomas, London.

15,627. Band-driving Gear, E. Dagnall, London.

15,628. Torpedo, W. Green, London.

15,629. Apparatus for "Chiming" the Staves of Casks, J. Russell, London.

15,630. Fastening Device for Collars, V. F. von Ried, London.

15,631. Spraying Liquids under Pressure, L. Rusden and R. Eeles, London.

15,632. Heating Crucibles, A. C. Girard and E. A. G. Street, London.

15,633. Dog Kennels, H. R. Newburgh-Stewart, London.

15,634. Hair-curling Device, E. F. Lewis, London.

15,635. Window Fasteners, H. J. Fox, London.

15,636. Sash Fasteners, F. Stewart, London.

15,637. Tap and Measuring Device, E. Clairmonte, London.

15,638. Cream Elevators, T. T. Sabroe, London.

15,639. Extinguishing Apparatus for Oil Burners, O. Wollenberg, London.

15 640. Switchback Railways, &c., E. Lacy, London.

15,641. Cutting Toothpicks, &c., R. F. S. Molesworth, London.

15,642. Inflating Pneumatic Tires, A. J. Boult.—(*R. Hoffmann, Germany.*)

15,643. Optical Lantern, J. Airs, London.

17*th August*, 1894.

15,644. Drying Stereo-matrices, R. H. Healey, London.

15,645. India-rubber Cushion for Chair Legs, W. F. Taylor, Sheffield.

15,646. New Game, J. H. Matthews and J. Jaques, jun., London.

15,647. Adjustable Drill Rest, J. Barlow and L. T. G. Evans, Nottingham.

15,648. Protecting the Ends of Bales of Paper, J. Grime, Halifax.

15,649. Swell Springs of Looms, T. Walsh and J. F. Lowe, Manchester.

15,650. Apparatus for Cooking, &c., E. W. Parish, Leicester.

15,651. Construction of Gully Traps, R. Lawton, Longport.

15,652. Cycle Foot-rests, J. A. Beard, Birmingham.

15,653. Cycle Lamp Brackets, J. A. Beard, Birmingham.

15,654. Pistons, S. H. Wright, Ganarew Manor House, near Monmoth.

15,655. Bottles, F. Holbrook, Derby.

15,656. Needle Case, A. B. Knight, London.

15,657. Condensation Lubricators, W. Graham and J. S. Fleming, Dundee.

15,658. Atmospheric Gas Burners, T. Fletcher, Manchester.

15,659. Mules for Spinning, S. H. Smethurst, Manchester.

15,660. Heel Protector, W. C. West, London.

15,661. Twisting Machinery, A. Combe and T. Magee, Halifax.

15,662. Securing Handles to Knives, W. Seedhouse and A. J. Hobson, Sheffield.

15,663. Spoke Grips, W. A. Lloyd and J. Blyth, Birmingham.

15,664. Felting Spherical Articles, T. M. Cockroft, Leeds.

15,665. Inducing Sleep in Cases of Insomnia, V. Gorgias, Liverpool.

15,666. Weighing Apparatus, J. Greenhough, Liverpool.

15,667. Trunk Box, L. Mansbridge, London.

15,668. Fluid Motors and Pumps, J. Bow.—(*J. Farquharson, Chili.*)

15,669. Combination Tube-expanding Drift, J. McKay, A. Young and A. Hardy, Newcastle-on-Tyne.

15,670. Composition Stairs or Steps, J. Lauder, Glasgow.

15,671. Preserving Sausage Skins, &c., J. McBride, Glasgow.

15,672. Folding Eye-glasses, J. Frohn, London.

15,673. Shutters for Photographic Cameras, J. B. Irving, Liverpool.

15,674. Boiler Furnaces, J. Sutton, Liverpool.

15,675. Vehicle Propelled by Electricity, E. S. Colchester, London.

15,676. Composition Paint, J. and A. Tennant, London.

15,677. Sliding Window Sash Holder, J. W. Evans, London.

15,678. Bakers' Ovens, R. H. Craine and D. C. Craine, London.

15,679 Double Centrolinead, J. H. Spanton, Dartmouth.

15,680. Increasing Adhesion between Rails and Wheels, J. C. Chapman and F. Holt, London.

15,681. Spanners, J. Chandler and A. Krafft, Manchester.

15,682. Puzzle, G. H. Mason, Birmingham.

15,683. Packing Glass for Transit, K. Fraser, jun., London.

15,684. Coal Economiser, S. A. Cackett and K. E. Darlow, London.

15,685. Games, A. Sweetser and G. Royle, London.

15,686. Furnace for Destruction of Refuse, T. B. Grant, London.

15,687. Pneumatic Boot Stretcher, H. W. C. Cox, London.

15,688. Fire-bars, C. H. Jones, West Bromwich.

15,689. Garment Pattern Delineated Materials, A. Kenealy, Herts.

15,690. Corsets, T. R. Williams, London.

15,691. Waterproof Mud Shield for Cyclists, J. J. Allan, London.

15,692. Ticket Punches, J. S. Comrie, London.

15,693. Knife-cleaning Machines, H. and E. White, London.

15,694. Electric Arc Lamps, E. H. Maret, London.

15,695. Velocipedes, J. Harrington, London.

15,696. Shirt-front and Stud Protector, E. Palmer, London.

15,697. Operating Valves of Engines, C. E. Beaumont and C. P. Wallington, London.

15,698. Electric Appliances for Boiling Liquids, F. W. Schindler, London.

15,699. Steam Boilers, C. Finger, London.

15,700. Employes' Time Recorders, N. M. Watson, London.

15,701. Stoppering of Bottles, B. M. Persicaner, London.

15,702. Treating Siliceous Material, S. B. Archdeacon, London.

15,703. Packing Cases for Ammunition, J. T. Coffin, London.

15,704. Photographic Cameras, R. Krügener, London.

15,705. Gas Cooking Stoves, C. Holmstrom, London.

15,706. Governing Marine Engines, &c., T. Casson, London.

15,707. Door, &c., Locks, T. Dace and A. Single, London.

15,708. Ventilating Boots and Shoes, W. H. Hunt, London.

15 709. Device for Holding Ropes, T. Lee and J. Edwards, London.

15,710. Bicycles, B. Madoc, London.

15,711. Bottles, R. Hornby, London.

15,712. Drying Voltaic Cells, D. B. Morison, London.

15,713. Tobacco Pipes, W. Y. Yates, London.

15,714. Securing Feminine Apparel, W. F. Beattie, London.

15,715. Device for Heating Irons, J. Rees, London.

15,716. Postal Envelopes, A. A. Hill, London.

15,717. Horseshoes, W. Smith, London.

15,718. Fire-proof Paper, H. H. Leigh.—(*C. B. Schneider, Holland.*)

15,719. Covers for Pneumatic Tires, J. Morran, London.

15,720. Packing Ammunition, W. J. Holt and J. Davis, London.

15,721. Hydrocarbon Engines, W. D. and S. Priestman, London.

18*th August*, 1894.

15,722. Variable Speed Gear, L. Tolch, London.

15,723. Twisting Fibrous Material, J. and R. S. Dawson, Bradford.

15,724. Dirt or Road Scraper, J. Tweedle, Birkenhead.

15,725. Saddles for Cycles, J. B. Brooks, Birmingham.

15,726. Water-tube Boiler, J. T. Jameson.—(*H. MacColl, Spain.*)

15,727. Cleaning Jute, C. Malley, J. Brett, and W. H. Hughes, Liverpool.

15,728. Panel for Painting, R. H. Bentham, Lancashire.

15,729. Preserving Buildings in Case of Fire, R. W. Papineau and C. B. Beresford, London.

15,730. Carding Engines, E. and W. H. Crowther Halifax.

15,731. Hydraulic Rams, P. Decoeur and W. H. Bailey and Co., Ld., Manchester.

15,732. Spindles for Doubling Frames, R. Taylor, jun., Manchester.

15,733. Measuring Distances, E. E. A. Schelin, London.

15,734. Apparatus for Breaking Coal, W. Pegge, Swansea.

15,735. Carbonating Drinks, T. Barker, Bolton.

15,736. Chlorhydric Acid, W. J. C. Marie, London.

15,737. Phonographs, A. Wilkinson, Bradford.

15,738. Heating Cylinders of Steam Engines, F. Hamer, London.

15,739. Spools and Bobbins, F. J. Ermen, Manchester.

15,740. Water-closets, L. Brandis, Germany.

15,741. Tobacco Pipes, C. Fulton and K. Fulton, Lancashire.

15,742 Fastening for Boots, &c., J. B. E. Field, London.

15,743. Apparatus for Flower-pots, W. C. Henderson, London.

15,744. Increasing the Draught in Boilers, H. C. Ashlin, London.

15,745. Supporting Curtains, T. W. Crowther, Liverpool.

15,746. Water-wheels, J. F. Hopkins, jun., Liverpool.

15,747. Coin-freed Gas Meters, H. Simmonds, Manchester.

15.748. Converting Reciprocating Motion into Rotary, F. van der Laan, Liverpool.

15,749. Writing Block Characters, G. C. Dymond.—(*C. A. Schoepff, Germany.*)

15,750. Boiler Furnaces, G. C. Rhodes and W. Topham, Bradford.

15,751. Bottles, J. Lindsay and J. Rogers, London.

15,752. India-rubber Rings for Jug Bottoms, C. R. Aitken, London.

15,753. Collar Stud and Tie Clip, H. Catton, Essex.

15,754. Police Call Whistle, &c., G. S. Rayson, London.

15,755. Repairing Stone Steps, &c., J. Elliott, Hastings.

15,756. Damp-resisting Materials, R. J. Goddard, London.

15,757. Oil Lamps, J. Chandler, Manchester.

15,758. Stage Illusions, J. N. Maskelyne, London.

15,759. Weighing Machines, T. E. Halford.—(*H. Siefert and G. Jaeger, Germany.*)

15,760. Pneumatic Tires for Cycles, W. Reithoffer, London.

15,761. Treating Zinc Ores in Furnaces, R. Biewend, London.

15,762. Metal Teapots and Urns, L. C. Davidson, London.

15,763. Agricultural Machine, P. A. Randall.—(*S. A. G. Hashim, Syria.*)

15,764. Carriage Springs, G. Hughes.—(*V. Candotti, South Africa.*)

15,765. Calendar Stand or Frame, C. Tyler, London.

15,766. Non-slipping Band for Tires, H. W. F. Mogg, London.

15,767. Railway Permanent Ways, H. Causeley, London.

15,768. Device for Fastening Gloves, W. J. Sanders, London.

15,769. Skirt Facing, E. C. Gauge, Bristol.

15,770. Electric Heating Apparatus, J. A. Kingdon, London.

15,771. Preventing Gas Explosions, C. Gautsch, London.

15,772. Confectionery, L. Fulda, London.

15,773. Burning Liquid Fuel, J. L. Osborn.—(*C. Neuhaus, Austria.*)

15,774. Electric Cables, H. A. C. Saunders.—(*R. Grecy and W. J. Murphy, ———.*)

15,775. Fire-resisting Curtains, &c., E. Taylor, London.

15,776. Cigarette Machines, G. A. Wills.—(*D. B. Strouse, United States.*)

15,777. Invert Sugar, J. Y. Johnson.—(*J. E. Pellegrini, Spain.*)

15,778. Alcohol, J. Y. Johnson.—(*J. E. Pellegrini, Spain.*)

15,779. Ink Stands, C. R. Söderström, London.

15,780. Manufacture of Soap, G. Stecken, London.

15,781. Roller Skates and Vehicles, G. Fauquet, London.

15,782. Carbon, C. P. Shrewsbury, F. L. Marshall, J. Cooper, and J. L. Dobell, London.

20*th August*, 1894.

15,783. Rails of Tramway Permanent Way, H. Cockill, Bradford.

15,784. Furnace for Heating Steel, &c., J. Immel, Berlin.

15.785. Self-acting Wheel, W. Shaw, Cumberland.

15,786. Joint Horse Bit, P. Spohr, Manchester.

15,787. Carbonising Machine, G. and J. E. Tolson, Dewsbury.

15,788. Rotary Engines, T. Firth, London.

15,789. Thermodynamic Motors, F. W. Crossley and J. Atkinson, Manchester.

15,790. Stable or Storm Lanterns, A. Shaw, Kilmarnock.

15,791. Dustbin, E. F. Thorpe, London.

15,792. Corrugated Sheet Glass, W. L. Pilkington, Liverpool.

15,793. Insect Traps, J. D. McNally, Liverpool.

15,794. Device for Moistening Labels, J. Grant, Derby.

15,795. Keels for Yachts, J. Leach, Southampton.

15,796. Automatic Inflated Sock for Boots, L. Wacks, Leicester.

15,797. Course and Heel Indicator, J. C. Dobbie, Glasgow.

15,798. Banjos, C. A. W. Drury, Bristol.

15,799. Oilers, T. H. Price and F. Westwood, Birmingham.

15,800. Waste Water Flushing Apparatus, J. Clayton, Denton.

15,801. Stop Valves, A. Turnbull, Glasgow.

15,802. Motors, J. Maynes and C. L. Watchurst, London.

15,803. Extinguisher for Lamps or Stoves, J. H. Ross, Birmingham.

15,804. Brooding Apparatus, J. Koch, Berlin.

15,805. Making Combustible Capsules, P. Nussbaum, London.

15,806. Wet Spinning Frames, J. Gamble and A. Combe, Halifax.

15,807. Winding Machines, A. Combe, Halifax.

15,808. Making Boots and Shoes, T. J. Paxton, Northampton.

15,809. Wicker Mud-guard for Velocipedes, J. Ives, London.

15,810. Pocket, G. W. More and H. C. Trulock-Campbell, London.

15,811. Chimneys, F. Jacks, Liverpool.

15,812. Springs for Cycle Saddles, T. Middlemore, W. A. de Lattre, and T. Evans, London.

15,813. Sewing Machines, F. A. Mills and J. Mundell, London.

15,814. Boxes for Powdered Substances, &c., G. H. Watkins, Liverpool.

15,815. Apparatus for Spinning Flax, J. V. Eves, Manchester.

15,816. Automatic Telegraph Apparatus, P. Douglas, Liverpool.

15,817. Stoves, J. Strecker, London.

15,818. Manufacture of Fireclay, &c., F. Young, Liverpool.

15,819. Curtain Slide for Magic Lantern, G. Davenport, London.

15,820. An Improved Bed Castor, W. J. Hobbs Margate.

15,821. Marking Stamps, C. H. Thompson, London.

15,822. Indicating the Names of Stations, W. Ralston, Manchester.

15,823. Oil Stoves, E. Rippingille and W. Brandon, London.

15,997. Eye-glass Frames, R. B. Fowler, London.
15,998. Impressing Advertisements, A. Pontefract, London.
15,999. Invalid Bedsteads, G. E. Gorham, London.
16,000. Bucket for Pumps, R. F. Hall, London.
16,001. Material for Protecting Clothing, P. Mercier, London.
16,002. Refining Metal, H. A. House, H. A. House, jun., and R. R. Symon, London.
16,003. Umbrella Frames, H. Ellis and B. G. Coleby, London.
16,004. Securing Trousers, I. Levy, London.
16,005. Air-tight Coverings for Jars, F. E. Hollyer, Brentford.
16,006. Cover for Pickle Bottles, H. S. T. Biscoe, London.
16,007. Coin-freed Mechanism, G. F. Gale and A. B. Holmes, London.
16,008. Umbrella and Parasol Frames, S. Learoyd, London.
16,009. Tie and Cuff Clip, M. Pelegrin, London.
16,010. Window Sash Fastener, C. L. Polden, London.
16,011. Gates, F. L. Godfrey, London.
16,012. Rowing Apparatus, E. Pink, London.
16,013. Ruling Device, A. R. Phillips, London.
16,014. Producing Solid Persulphate of Sodium, R. Loewenherz, London.
16,015. Tool for Cutting Chips, K. A. Seifert, London.
16,016. Velocipedes, E. C. F. Otto, London.
16,017. Envelopes, S. W. Pedley, London.
16,018. A Clip for Securing the Ends of Bags, J. A. Jacobs, London.
16,019. Pull-out Drawers, C. Hass, London.
16,020. Appliance to Issue Disinfecting Paper, H. S. T. Biscoe, London.

23*rd August*, 1894.

16,021. Pivot Sash, C. Buchanan and J. Barr, Glasgow.
16,022. Apparatus for Securing the Doors of Hoists, B. Wright, London.
16,023. Ceiling Decoration, M. Smith, Liverpool.
16,024. Machines for Cleaning Boots, F. W. Follows, Manchester.
16 025. Bag Blue, R. Ripley, Liverpool.
16,026. Joining Earthenware and Metal Pipes, J. M. Ball, Manchester.
16,027. Steel Wire Winding Ropes, W. B. Brown, Liverpool.
16,028. Apparatus for Ice-making, &c., A. Glasson, London.
16,029. Drawing of Circular Arcs, T. Clarkson, Sutton.
16,030. Button-holes, A. M. Heath, London.
16,031. Window Sashes, J. P. Sinclair, Glasgow.
16,032. Flour Reduction Machine, A. R. Tattersall, London.
16,033. Covers to Tobacco Pipes, R. W. Tayler, Bury St. Edmund's.
16,034. Hair Crimpers, H. Maudsley, Accrington.
16,035 Cycles, D. P. Schloss and C. S. Madan, Manchester.
16.036. Lamp-globe Holders, D. H. Croll and C. de'Vere Grant, Hertford.
16,037. Method of Fastening Hampers, T. Reed, London.
16,038. Cabin Trunk, H. A. Norman, Liverpool.
16,039. Illuminating Designs for Leather, W. Evans, Walsall.
16.040. Manufacture of Fluorescent Soaps, S. Neumann, Manchester.
16,041. Coating of Metals, W. K. Greenway, Birmingham.
16,042. Fire-arms, W. Mitchell, Southampton.
16,043. Kilns for Burning Limestone, W. Spencer, Keighley.
16,044. Drawing-off Water from Ships' Decks, W. Collinson, Stockton-on-Tees.
16,045. Device for Holding Food, H. Thompson, London.
16.046. Raising Weights, H. Clark, Stockton-on-Tees.
16,047. Burners for Gas Fires, H. Darwin, Glasgow.
16,048. Sewing Machines, J. Fletcher and C. Brown, Halifax.
16,049. Spring Tongues for Bottle Necks, C. H. Fernley, Manchester.
16,050. Hooks for Securing Boot-laces, F. J. Commin, Exeter.
16,051. Disinfecting Public Buildings, G. Bullock, London.
16,052. Window Sash Fastener, R. Whitehead, Sheffield.
16.053. An Improved Candlestick, S. L. Jones, Bristol.
16,054. Cycle Saddle Attachments, D. A. Martin, Birmingham.
16,055. Extracting Juice from Canes, A. G. Berry, Glasgow.
16,056. Covering Ricks of Hay, &c., S. Harding, Bristol.
16,057. Hairpins, C. Crowther, Manchester.
16,058. Water Heaters, J. Yates and W. Yates, Manchester.
16,059. Coin-freed Apparatus, R. Massow, Manchester.
16,060. Driving Gear for Cycles, J. J. Raggett, Birmingham.
16,061. Adjusting Cycle Handles, G. Patterson, Birmingham.
16,062. Domestic Boilers, T. and W. Slater, and W. Crumblehulme, London.
16.063. Cases for Medicine Bottles, W. Oppenheimer, London.
16,064. Blankets, R. M. Bell, Llanidloes.
16,065. Tobacco Pouch, J. H. Edgar, Droylsden, near Manchester.
16,066. Fishing Lines, C. W. Aitken and A. Kay, Edinburgh.
16,067. Making Hydrosulphurous Acid, J. Grossmann, Manchester.
16,068. Making Hydrosulphurous Acid, J. Grossmann, Manchester.
16,069. Roller Blind Furniture, G. Burn, Birmingham.
16,070. Combined Letter Sheet and Envelope, D. McIntyre, Glasgow.
16,071. Extraction of Gold and Silver, H. R. Angel, London.
16,072. Tramcars and similar Vehicles, E. Böhm, London.
16,073. Decoration of Glass, E. Böhm, London.
16,074. Fastening Wire, T. Pike and S. Payne, London.
16,075. Appliances for Branding Animals, G. Daws, London.
16,076. Double Cock for Beer Engines, J. Systermans, London.
16,077. Air Valve, J. Schiönning and J. P. Möller, London.
16,078. Relief Stamping Machines, T. B. Kendell, London.
16,079. Casks, R. Perron, London.
16,080. Fare Indicators for Vehicles, O. Schneider, London.
16,081. Steam Engines, B. Lebrun, London.
16,082. Velocipedes, O. Wartmann, London.
16,083. Ethenyldiphenylamidines, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)
16,084. Rolling Mills, A. Thomas, London.
16,085. Paper Boxes, H. H. Lake.—(*E. H. Taylor, United States.*)
16,086. Surgical Trusses, &c., F. T. Simmons, London.
16,087. Artificial Fuel, G. S. Cory and C. Cory, London.
16,088. Postal Envelopes, E. Guesdon, London.
16,089. Travelling Boxes, &c., A. M. Jones, London.

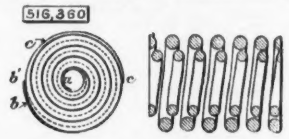
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**516,360.** Spring, *G. Turton, Sheffield, England.—Filed March 16th*, 1893.

*Claim.*—(1) A compound or multiple spring consisting of inner and outer coils connected or united at one point in their length substantially as described, and formed of bars of such relative length that they terminate at diametrically opposite points in the spring, as and for the purposes above specified. (2) A volute spring consisting of inner and outer coils formed of bars tapered at both ends, which bars are connected or united at one end, and are of such relative length that they terminate at diametrically opposite points in the spring, and thus form a stable base therefor, substantially as and for the purpose above specified. (3) A compound or multiple spring consisting of the coils *b c* connected or united at *a*, and terminating at diametrically opposite points *b' c'*, substantially as and for the purposes above specified. (4) A spring consisting of inner and outer coils united at one point in their length, and having a conical or taper portion A—B and a parallel or cylindrical portion A—C at the smaller end thereof, substantially as hereinbefore described

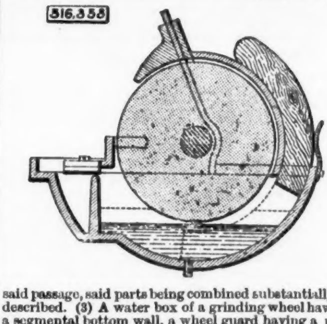
516,360



**516,353.** Water Box of Grinding Wheels, *F. M. King, Philadelphia, Pa. — Filed September 19th*, 1893.

*Claim.*—(1) A water box of a grinding wheel having a wheel guard with a rear wall forming a passage between it and the bottom wall of the box, a plug movable in said passage, and means for retaining said plug in place, said parts being combined substantially as described. (2) A water box of a grinding wheel, a wheel guard having a rear wall forming a passage with the bottom wall of the said box, and a plug fitting in said passage, said parts being combined substantially as described. (3) A water box of a grinding wheel having a segmental bottom wall, a wheel guard having a rear wall forming a passage-way with said segmental bottom wall, a movable plug fitting in said passage-way, and a catch bearing against said plug, said parts being combined substantially as described.

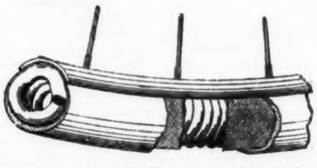
516,353



**516,201.** Wheel Tire, *E. Grenet, Paris, France.—Filed July 7th*, 1893.

*Claim.*—A tire consisting of an outer casing of flexible material and a continuous coil of rubber spirally arranged within the casing, substantially as described.

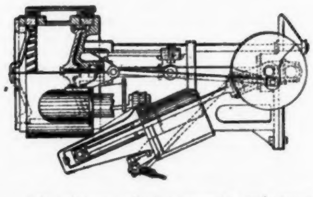
516,201



**516,442.** Blowing Engine, *C. A. Klotz, Vallejo, Cal.—Filed May 22nd*, 1893.

*Claim.*—The inverted vertically acting air compression cylinder provided with admission and discharge ports, an inclined steam cylinder in the same plane, with the axis converging to the centre of the common crank shaft, with which both pistons are connected by approximately oppositely fixed cranks, counterbalance weights on said crank shaft, a cylindrical valve surrounding the air cylinder, excentric rods connecting with pins projecting from the outer faces of the counterbalance weights, whereby the air valve is reciprocated and counterbalanced, and a connection between said excentric rod and the rocker arm of the steam cylinder valve, whereby the latter is actuated simultaneously and from the same excentric, substantially as herein described.

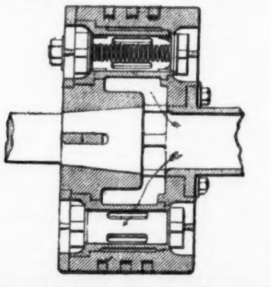
516,442



**516,594.** Fluid Pressure Engine, *G. Dixon, Bolton.—Filed August 16th*, 1893.

*Claim.*—The combination of an engine cylinder provided at each end with a port or ports serving alternately as a steam port and as an exhaust port, valves for controlling the admission of steam and exhaust of motive fluid, a hollow piston formed at its respective sides with ports controlled by non-return valves, springs that normally hold said valves against their seats but each adapted to permit the appropriate valv or valves to automatically open when the pressure at either side of said engine piston falls below that of the hot gases supplied to the interior of said piston, a pump cylinder provided at its ends with inlets for hot gases controlled by non-return valves, a hollow pump piston formed at its respective sides with inlet ports fitted with non-return valves opening inward, springs adapted to hold said valve against their seats at each suction stroke of the pump piston and to permit said valves to open during each compression stroke, and a hollow rod connecting the engine and pump pistons and serving to place the interior of the one in communication with that of the other substantially as described.

516,594



# NOTES ON THE STRENGTH OF FRAMED STRUCTURES AS AFFECTED BY ELASTICITY.

By C. F. FINDLAY, M.A., M. INST. C.E.

(*Concluded from page* 118.)

## SECTION II.—SECONDARY BRACING.

BY this term we mean the bracing by which the main elements of a built-up tie or strut are connected together, in order to enable it to resist stresses of various kinds other than the primary stress, and also in order to check vibration. In regard to the latter, it need only be said that however desirable it may be to avoid the use of long, unsupported, light ties which vibrate freely under moving loads, there is no reason to suppose that such transverse vibrations give rise to appreciable stresses, or are any direct source of weakness. They may be *indications*, but they are not causes of variations of stress with moving loads. The vibration of a bridge—*as a whole*—in the vertical plane is, on the other hand, some sort of measure of the variations of stress due to the impacts of a moving load. It is accompanied by variations of stress in each member of the bridge, and the secondary bracing does nothing to check those variations.

The purposes which secondary bracing serves directly are (1) in struts or columns to resist distortion by flexure; and (2) to give the transverse strength necessary to prevent the weight of the link itself from causing appreciable flexure. As regards the latter purpose, where the weight and length of the link are considerable, its effects can be calculated and allowed for in the scantlings; and, when this is done, it may be desirable to give the link an upward camber, such that its own weight will bring its axis into a straight line, or nearly so. For secondary bracing in general, it seems to be commonly supposed that it takes no share in the primary stress, and that, so long as it is sufficient in amount, the disposition of it is a matter of no consequence. As soon as the deformation begins to be considered, however, it is clear that the primary stress must necessarily be shared by the bracing. The fact that it has been allotted a separate *rôle* by the designer will not prevent it from taking such stress as its place in the structure assigns to it. Consider, for instance, a strut braced as in Fig. 8, all the bracings making the same angle $\alpha$ with the main ribs of the strut. Let S be the section of the main ribs 1, 2, 3, &c., and $m$ S the section of the bracings 5, 6, &c. Let W be the load on the strut. Then

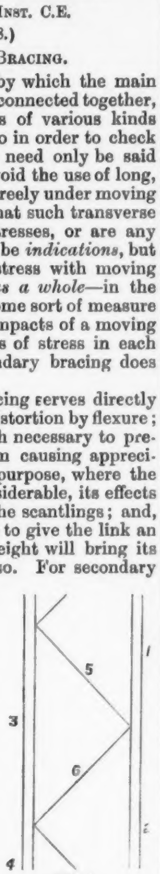


FIG. 8

$$\left.\begin{aligned} -\mathrm{W} &= \mathrm{S}\,(t_1 + t_3 + m\,t_5 \cos\alpha) \\ &= \mathrm{S}\,(t_3 + t_2 + m\,t_6 \cos\alpha) \\ \text{and}\qquad m\,\mathrm{S}\,(t_5 \sin\alpha + t_6 \sin\alpha) &= 0 \end{aligned}\right\}$$

$$\left.\begin{aligned} \text{whence}\qquad t_5 &= -\,t_6 \\ \text{and}\qquad t_1 - t_2 &= 2\,m\,t_6 \cos\alpha \end{aligned}\right\}$$

These equations indicate two possible conditions of equilibrium. Either the strut may widen out, as it shortens under stress, to such an extent that the bracing bars remain of the same length as before and are not strained at all, or it may take a definite flexure by which alternate bars will be in tension and compression. The former would be an unstable condition, which could scarcely occur in practice. In the latter condition, which would in practice be the only possible one, we see that there would be a constant transfer of the load from one side of the column to the other throughout its whole length. The bracing itself, therefore, causes a flexure, such as is shown exaggerated in Fig. 9, to occur.

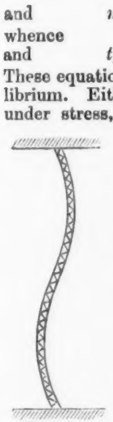

FIG. 9

It is only where the bracing is of the symmetrical character shown in Fig. 10, that the column can contract without flexure. Let $\alpha$ be the angle made by the diagonals with the main ribs, and $S_1$, $S_2$, $S_3$, the cross-sectional areas of the members denoted by these figures.

By static resolution

$$\left.\begin{aligned} -\mathrm{W} &= 2\,t_1\,\mathrm{S}_1 + 2\,t_2\,\mathrm{S}_2 \cos\alpha \\ t_3\,\mathrm{S}_3 + 2\,t_2\,\mathrm{S}_2 \sin\alpha &= o \end{aligned}\right\} \quad \begin{aligned} &\ldots\ (\mathrm{I.}) \\ &\ldots\ (\mathrm{II.}) \end{aligned}$$

The condition that there is no flexure is, that the angle between 1 and 3 remains at a right angle. From the formula in section (I.) this condition is expressed by the equation :—

$$(t_2 - t_1) \cot\alpha + (t_2 - t_3) \tan\alpha = o$$
$$\text{or } t_1 \cos^2\alpha = t_2 - t_3 \sin^2\alpha \quad \ldots\ (\mathrm{III.})$$

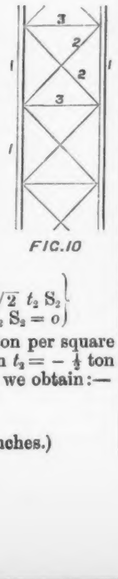

FIG. 10

Now, $t_1$ is negative, and by Equation II., $t_2$ and $t_3$ are of opposite signs; therefore $t_2$ is negative, and $t_3$ is positive. That is to say, $t_2$—by Equation I.—shares in supporting the load in a degree depending on the section given to the diagonals and main ribs respectively, and $t_3$ is a tension, sufficient to resist the outward thrust tending to widen the column. Clearly for economy it is desirable to reduce $S_2$ and $S_3$ as low as possible. At the same time $t_3$ should be small, in order that the column should spread very little, and so the secondary stress be small.

$$\text{Suppose } \alpha = 45 \text{ deg.}\quad \text{Then } \left.\begin{aligned} t_1 &= 2\,t_2 - t_3 \\ -\mathrm{W} &= 2\,t_1\,\mathrm{S}_1 + \sqrt{2}\;t_2\,\mathrm{S}_2 \\ t_3\,\mathrm{S}_3 + \sqrt{2}\;t_2\,\mathrm{S}_2 &= o \end{aligned}\right\}$$

If we allow, for example, $t_3$ to be one ton per square inch, and $t_1 = -\,2$ tons per square inch, then $t_2 = -\,\frac{1}{2}$ ton per square inch. Substituting these values we obtain :—

$$\left.\begin{aligned} \mathrm{S}_3 &= 0{\cdot}7\ \mathrm{S}_2 \\ \text{and } 4\,\mathrm{S}_1 + \mathrm{S}_3 &= \mathrm{W} \end{aligned}\right\}$$

(W being in tons, and S in square inches.)

In order that $t_1$ and $t_3$ may have the assumed values, it is sufficient, therefore, that the sections be chosen making $\mathrm{S}_3 = \frac{7}{10}\,\mathrm{S}_2$ and $\mathrm{S}_1 = \frac{\mathrm{W} - \mathrm{S}_3}{4}$. It is clear that the smaller $S_2$ and $S_3$ are, the smaller is the amount of material used in the column, and that increase of section in the bracings does not necessarily imply greater strength.

On what principle, then, can we determine what strength of bracing should be used for a given column? Practice at present varies exceedingly and capriciously. A rational basis may be found as follows:—Suppose it is decided, according to any column formula adopted, that the proper mean stress for a given column is $t$ tons per square inch, while the safe load for a short specimen of the same material is $t^1$ tons per square inch—*i.e.*, let it be assumed that the stress in the innermost or most strained fibres may safely amount to $t^1$. The width of the column is supposed to be so fixed that when the stress $t^1$ in the extreme fibres is reached, the flexure of the column will not exceed the small limits consistent with the safety of other members of the structure.

The stress in the outermost fibres would be $2\,t - t^1$, if the column is symmetrical, when that on the innermost fibres is $t^1$. It follows that the column has been designed to resist safely a bending moment amounting to

$$\frac{2\,(t^1 - t)}{d} \times \mathrm{I},$$

in addition to the uniformly distributed stress of $t$ tons per square inch, where $d$ is the total width of the column and I the moment of inertia of cross-section. Now, it can be shown by the method of investigation in the appendix to Section I., that the transverse shearing stress on the column will have a maximum value of nearly $\frac{2\,\mathrm{M}}{l}$, where M is the maximum bending moment.

$S_1$, the transverse shearing stress in the column to be provided against, is therefore $\frac{4\,\mathrm{I}}{l\,d}\,(t^1 - t)$. Since $\mathrm{I} = \frac{\mathrm{P}\,\rho^2}{t}$, where $\rho$ is the radius of gyration, and P the load on the strut, this expression may be written

$$\mathrm{P} \times \frac{4\,\rho^2}{l\,d}\left(\frac{t^1}{t} - 1\right).$$

Take the case of a latticed strut in the American truss bridge referred to above. It is 25ft. long between bearings, 1ft. wide, with a radius of gyration of 4in., and a total stress of 21 tons. Suppose $t^1 = 5$ tons per square inch, $t = 1{\cdot}5$ (see Table III., page 162),

$$\text{shearing stress} = 21 \times \frac{4}{9 \times 25} \times \frac{7}{3} = 0{\cdot}9 \text{ tons nearly.}$$

It may at first sight seem contradictory to establish relations between the sections on the supposition that no flexure occurs, and then to determine the strength of the bracing on the assumption of flexure. There is really no contradiction, however. The desirable condition is that of no flexure, and the column should be so designed that such a condition should be possible. We may fulfil that condition, and still the scantlings necessary for the bracings are indeterminate, though the ratios of one to another can be settled. Having thus made the best condition for the column a *possible* one, we turn to another view of the case and make the worst condition a *safe* one.

## SECTION III.—RESISTANCE AT BEARINGS.

As pointed out at the outset, it is assumed in the usual methods of calculating frames that one point of the frame is fixed and another free to move without resistance on a given straight line, while otherwise the frame is free from all constraint. In the case of bridges of large size, the usual method by which it is attempted to realise this condition is that of supporting the main girders on curved bearing blocks, which leave the girders free to change their inclinations at the bearings, while the blocks at one end rest on rollers placed upon a level bed-plate, which is supposed to provide the means of longitudinal expansion. This apparatus, as usually constructed, is very far from realising the ideal condition contemplated by the calculations.

With small bridges and with roof trusses, it is usual to provide for expansion by leaving one end free to slide on a horizontal plate. There are many other cases of frames where no provision for expansion is made at all, and where, nevertheless, the calculations are made as if there was no constraint, as, for instance, in the frequent case of the purlins of an iron roof.

Where provision is made for expansion, it is usually regarded as being required on account of changes of temperature only. Very little consideration, however, is needed to show that, generally speaking, the same provision is equally essential to the theory, on account of the deformations of the frame when strained. In a girder, it is only the points lying on the neutral axis which do not change their horizontal distances from each other under strain, and the bearings of a girder are rarely placed on the line of the neutral axis. The horizontal movement on the expansion bearing of a bridge, which would take place from this cause if no resistance were offered, is quite comparable with the expansion from rise of temperature. If $t_1$ and $t_2$ be the stresses per square inch caused in the booms by certain loads—of which $t_2$ is negative—$t_1$ and $t_2$ being supposed constant throughout the girder, then the spread of the supports owing to deformation by these loads is approximately $\frac{l}{d} \times \frac{t_1 - t_2}{\mathrm{E}} \times a$, where $l$ is the span, $d$ the depth, and $a$ the distance below the neutral axis at which the girder is supported. When, as is usually nearly the case, the supports are in the line of the axis of one of the booms, this expression becomes $\frac{t_1}{\mathrm{E}}\,l$, or $\frac{t_2}{\mathrm{E}}\,l$, as the case may be. In the illustrations already used in Section (I). both bridges are supported somewhat below the axis of the lower boom. For the English bridge $t_1$—from live load only—is about 2·2, and in the American bridge 2·9, so that the horizontal movement at the bearing, taking $l$ as 150ft. and E as 11,000 tons, due to the imposition of the full moving load, is in the one case $\frac{2{\cdot}2 \times 1800}{11{,}000}$, and in the other $\frac{2{\cdot}9 \times 1800}{11{,}000}$, measured in inches, or in one case 0·33in. and in the other 0·47in. These amounts are equal respectively to the expansion due to a rise of temperature of 27 deg. Fah. in one case and 39 deg. in the other.

With a rapidly moving load, the frictional resistances that arise at the bearings must not only modify the stresses in the bridge, but also give rise to vibrations. As the load enters on the bridge no expansion will take place till the frictional resistance reaches its limiting value: when that limit is reached a very small expansion will instantaneously take place till a fresh position of equilibrium is reached, which will again be destroyed in the same way, as soon as it is established; and thus a series of longitudinal vibrations must be produced which will be more violent as the speed of the load crossing the bridge is greater.

As regards the actual stresses caused by the resistance to expansion, the first question to decide is what the frictional resistance may be expected to be for a given bearing; and the second question is what stresses that resistance would give rise to in the frame.

The rollers which are inserted under bridge bearings, to reduce the resistance, are often inoperative after a few years' exposure to weather and to the accumulation of dirt about them. They are usually difficult of access and the maintenance necessary to their efficiency is neglected, as we have verified by examination of several cases where it was clear that the expansion took place, so far as it took place at all, by sliding of the upper casting on the top of the rollers. It is a matter for the judgment of the engineer in each case as to whether the expense of providing apparatus which may possibly be worse than useless—for if it should do no good it will do harm—is justified, and whether the same money might not be better expended in securing the bridge and its piers from any injury that could be caused by the maximum frictional resistance which could occur with plane sliding surfaces. Where a sliding expansion joint is provided, the coefficient of friction, for the usual condition in which the bed plates of bridges are to be found after many years' use, and seeing the impossibility of securing a perfect adjustment, cannot safely be assumed at less than 0·5. For a freely supported girder with a total load of W, we should therefore in ordinary cases expect that the horizontal forces at the bearings resisting movement would have a limiting value of $\frac{\mathrm{W}}{4}$, the vertical reaction being $\frac{\mathrm{W}}{2}$. Leaving out of consideration all secondary stress, equal and opposite horizontal forces applied at the bearings will produce a stress of the same amount in the boom to which the bearing is attached, and will not affect the other members of the girder. Thus, if the horizontal resistance be $\frac{\mathrm{W}}{4}$, the reaction at the abutment will be inclined at an angle of 27 deg. to the vertical, and will be the resultant of the vertical force $\frac{\mathrm{W}}{2}$ and the horizontal force $\frac{\mathrm{W}}{4}$.

Suppose the girder to be of the type shown in Fig. 11, with diagonals at 45 deg. The primary stress in the end member of the lower boom is $\frac{\mathrm{W}}{2}$, which may by reason of the frictional resistance be diminished to $\frac{\mathrm{W}}{4}$ or increased to $\frac{3\,\mathrm{W}}{4}$. A small change of temperature is sufficient to bring this about. Suppose $t$ tons per square inch to be the stress in this link due to the dead load W alone, and S the sectional area in square inches. Then $t\,\mathrm{S} = \frac{\mathrm{W}}{2}$ and $\frac{t}{2}\,\mathrm{S} = \frac{\mathrm{W}}{4}$. Therefore $\frac{t}{2}$ is the stress caused by the resistance $\frac{\mathrm{W}}{4}$. Now a bar of wrought iron extends under a stress of one ton per square inch by about the same amount as for a rise of temperature of 13½ deg. Fah. Therefore a change of temperature of $\frac{27\,t \text{ deg.}}{4}$ will produce a stress of $\frac{\mathrm{W}}{4}$ in the bar. In the English bridge used as an illustration in Section (I.), $t = 2$—nearly—and in the American bridge $t = 1{\cdot}3$. Therefore in the former case a change of temperature of 14 deg., and in the latter case a change of 9 deg., will give rise to the maximum frictional resistance with a coefficient of ½. To state the case more generally, let W be the total dead load and $\mathrm{W}^1$ the total live load on a girder, both symmetrically distributed on the span. Then the maximum stress arising from change of temperature in the boom to which the bearings are attached is $\pm\frac{\mu\mathrm{W}}{2}$, where $\mu$ is the coefficient of friction.

Turning to the resistance offered by the bearings to the deformation of the girder from live load only, we see that this will give rise to a maximum stress amounting to $\frac{\mu\mathrm{W}^1}{2}$ (for the numerical calculation given above for a hypothetical case shows that the deformation may call into play the full amount of friction). Now this latter stress is always opposite in sign to the primary stress in the boom affected by it, and relieves the boom to that extent. Therefore the net effect of these two causes, when a rise or fall of temperature occurs, is to *diminish* the maximum stress in the boom affected by an amount varying between $\frac{\mu (W^1 + W)}{2}$ and $\frac{\mu (W^1 - W)}{2}$. With the type of girder shown in Fig. 11, the maximum primary stress in the end length of lower boom is $\frac{W + W^1}{2}$, which becomes therefore, when the frictional resistance is considered, a quantity varying between $(1 - \mu)\frac{W + W^1}{2}$ and $(1 - \mu)\frac{W^1}{2} + (1 + \mu)\frac{W}{2}$. The stress in the same link when the bridge is unloaded will vary between $\frac{W}{2}(1 \pm\ )$. We therefore see that, when a girder of this kind is supported near the line of one of its booms, the stress in the boom will be diminished and not increased by friction at the bearings unless W is $> W^1$.

---

* See also on this point Stoney on "Theory of Stresses in Girders," new edition, p. 493.

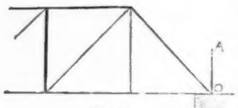

FIG 11

This condition of the dead load being greater than the maximum permissible live load is not reached in railway bridges except in spans of 200ft. and over, unless a heavy system of flooring be adopted. Even when the dead load exceeds the live load allowed for, the increased stress from temperature will be small except for very large spans. Expressed as a fraction of the primary stress, it is

$$\frac{\mu (W - W^1)}{(W + W)}.$$

The stress will not be reversed by temperature in the lower boom of a girder of type of Fig. 11, unless $\mu$ is $> 1$. But with a girder of the type of Fig. 12 there must of course be compression in the end length of the lower boom, and it should always be built as a compression member.

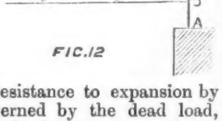

FIG. 12

The general conclusion to be drawn is that, as far as the bridge is concerned, there is in most cases nothing to be gained by reducing the coefficient of frictional resistance to expansion below the usual value for sliding, where the moving load is a large proportion of the total load provided for. The limiting resistance to expansion by change of temperature is governed by the dead load, and the frictional resistance to the deformation produced by the live load goes to relieve one boom or the other of the bridge at the expense of the abutment or pier. It is, however, of great importance to provide by rockers or otherwise for the angular deformation of a girder at its bearings, because otherwise heavy secondary stresses would be produced in the members meeting at the abutment.

The real advantage gained by the use of expansion rollers, when they are effective, is that the load on the piers or abutments is vertical or nearly so, and that advantage may be taken of this to reduce their dimensions below what would be necessary with an oblique load. We do not find, however, that engineers have had the courage to carry the use of rollers to this logical issue, because the piers of bridges show no weakness where the rollers have ceased to act; nor indeed would it be safe to design a bridge pier without a large provision for obliquity of the load, such as might arise from various contingencies. One important and inexpensive protection to a pier on which two adjoining spans rest is often neglected, viz., to connect firmly together, or to make in one piece the bed plates of the two spans. The frictional resistances of the two spans will rarely be equal, but are nearly always opposite; and the horizontal thrust or pull of one against the other should not be transmitted through the masonry.

If it be desired to reduce the possible obliquity of the load on a pier or abutment—an object in some cases of great importance—a much more reliable though less common plan than that of using expansion rollers is to suspend the bearing of the bridge from a centre fixed to the pier, or to use the same arrangement inverted. Let A O be the link by which the bridge is supported from the fixed point A, in Fig. 11 or Fig. 12, and $b$ inches its length between centres. Let $r$ be the radius of the pin or knuckle at each end of the link, and tan $\phi$ the coefficient of friction for the link A O at its bearings. The extreme obliquity of the line A O will be the angle whose sine is $\frac{c}{b}$, where $c$ is the extreme movement of O from the vertical through A. If $b$ be of sufficient length to answer the intended purpose, the expansion may be considered to be practically free; $c$ may amount at the most to about 2in. for each 100ft. of span, and will be much less if the position of A is fixed with care. The obliquity of the line of pressure at A to the vertical will then be $\sin^{-1}\frac{c}{b} + \sin^{-1}\frac{2r \sin \phi}{b}$. Sin $\phi$ will not be far from the value $\frac{1}{2}$: $\frac{c}{b}$ and $\frac{r}{b}$ should both be small. The maximum obliquity of pressure will, in that case, be an angle with the vertical whose circular measure is, roughly, $\frac{c + r}{b}$. We see, therefore, that to be of practical service, the pendulum must be of considerable length. Suppose we desire to limit the obliquity of the pressure to the angle $\frac{1}{10}$, for a 100ft. span resting on a 4in pin: $b$ would be determined by the equation $\frac{4}{b} = \frac{1}{10}$ or $b = 40$in. Short cast iron knuckles with large radii to their curved ends, such as have been proposed for this purpose, may give a larger resistance to expansion than a sliding bed-plate.

It is probable that the success which in practice has attended the use of expansion apparatus of both types, is due largely to its having failed to fulfil the purpose for which it was designed. If the condition be pictured to one's mind of a bridge which responded instantly and without resistance to the smallest longitudinal effort, it would probably be too lively under a rapidly moving load to give satisfaction. It would be more satisfactory, from the mechanical point of view, if the bearings could be placed near the line of the neutral axis; but this condition cannot generally be realised without undesirable complications.

---

## THE IRON AND STEEL INSTITUTE.

The largest party for the excursions on Thursday morning visited the Mariemont and Bascoup Collieries, leaving Brussels by a train starting ten minutes later than that conveying the visitors to Haine St. Pierre for the engineering and glass works in the same neighbourhood. These collieries, which rank high among the most important enterprises in the country, have been formed by the consolidation of two older concessions, and, taken together, cover about fourteen square miles of the coalfield of Hainault, the area included in Mariemont being 4065 acres, and that in Bascoup 4720 acres, of which nearly a quarter—2127 acres—represent freehold lands, woods, farms, and other buildings. The surface is formed by secondary strata covering a ridge in the older rocks known as the Comble du Nord, which render the lower coal measures accessible within moderate depths—from 130 to 650 yards in Mariemont, and from 260 to 660 yards in Bascoup, the latter division having seventeen and the former twenty-five workable seams, varying in thickness from 14in. to 41in. The total output of 1,100,000 tons per annum, divided in the proportion of five to six between the two concessions, is supplied by ten pits which are connected on the surface by a system of endless chain roads about six miles in length, with central, screening, picking, and washing works in each division, the same system of traction being applied on about 7½ miles of roads underground. The most important centre of production, the No. 5 Bascoup pit at Trazegnies, was selected for inspection by the nstitute. This includes in the same buildings the winding, pumping, and ventilating machinery for a pair of pits, together with the screens, picking tables, and washing machinery for small coal, the whole being covered by corrugated iron roofs of sufficient height in the centre to enclose the pit frame, a substantial iron structure with tubular standards and back legs, about 80ft. high. The winding is done in three-decked cages, each carrying two tubs with 9 cwt. of coal, making a useful load of 54 cwt. for each lift, which is drawn from a depth of 266 yards in 32 seconds; the landing of the full tubs and caging the empty ones taking 30 seconds more — corresponding to 150 tons drawn per hour when the engines are fully employed. The landing arrangements in strong contrast to the large amount of refined machinery about the pit top, are of a decidedly primitive character. A line of six or eight women standing close to the pit-brow join hands when the cage arrives at the surface, and pull the tub out, giving it sufficient impetus to run to the tippler, where it is emptied on to the first screen, which takes out the largest lumps. The different sizes of cobbles, large and small nuts, the latter locally known as *têtes de moineaux*, or sparrow heads, and slack being separated in other screens combined with rotating picking tables, where the shale and dirt are sorted out by hand, the finest sizes being purified by washing in Luhrig Coppée jigging machines. Owing to the friable character of the coal, very great care is taken to prevent breakage, the screens being laid at as low an angle as possible, the delivery being assisted by the oscillating tail bars invented by Mr. A. Briart, the chief engineer of the company. Travelling belts formed of old aloe fibre pit ropes are also largely used for intermediate transmission of the coal between the screens and the points of final delivery.

The coal produced is in considerable demand for household use and boiler firing, being comparatively low in volatile matter, but coking coals are also raised in several of the company's pits.

The main winding engines are of the vertical direct-acting class, with cylinders 32in. in diameter and 5ft. stroke, bringing the cage to the surface in $13\frac{1}{8}$ revolutions, which corresponds to a diameter of about 21ft. in the drum. The engineman is placed on a platform at a level of the axis of the drum, having the winding, indicator, reversing, and brake gear at hand, but out of sight of the main engines. The initial steam pressure is 86 lb. atmospheres in the boilers and nearly 85 lb. at the engines, which are provided with the well-known expansion gear due to Mr. L. Guinotte, the general manager of the company. The same gear is attached to the engines working in the second pit, which is enclosed in the same building. These are devoted to pumping, ventilating, and the Warocquére or man engine, so named from the inventor, the late M. A. Warocqué, the former general manager of the company. These engines, which are used in several of the mines of the group, there being two in Mariemont and three in Bascoup, are of a more elaborate construction than the main engines of metalliferous mines, the reciprocating rods being driven by water circulating under pressure instead of the older system of bell cranks and sweep rods—the effective lift per stroke being about 16ft. The relative position of the platforms can be seen at any moment by a large indicator at the surface, divided into ten equal parts, each about 20in. long. The water is circulated by a pair of single-acting plunger pumps, of larger diameter and correspondingly shorter stroke than the rods, driven by a small vertical engine, the necessary change in speed being obtained by a somewhat complicated train of bevel and spur gearing wheels. For pumping, two unequal armed beam engines, exactly similar in dimensions and construction, are provided, but only one is kept at work at a time. These are of the Seraing pattern, with Guinotte slide valves and connecting-rods and fly-wheels on the steam side, the cylinder is 54in. diameter and 11½ft. stroke, reduced to 8ft. 2in. in the pumps. The total lift of 266 yards is divided over three sets of pumps, having an effective area of 2·15 square feet, and delivering 500 litres—110 gallons—of water per stroke. Engines for the ventilating fans, which, like the pumps, are provided in duplicate, and for electric lighting, complete the contents of this spacious machinery hall. Owing to the large size of the party it was difficult for their guides to give verbal explanations as to details except to a limited extent; but considerable assistance was afforded to the visitors by a series of working drawings of the engines placed upon the walls, and indicator diagrams both for the winding and pumping engines were freely distributed among them. There was so much to be seen at this pit that the hour for departure was reached without its being possible to carry out the proposed inspection of the workmen's dwellings adjoining, a further obstacle being presented by the heavy rain which fell persistently during the morning. The party therefore assembled at the Chateau of Trazegnies, a picturesque seventeenth century house which has been acquired as a headquarters for the associated companies, where refreshments were served, and after an appropriate acknowledgment by the president of the kindness of their entertainers, the return to Charleroi was made by train.

In the afternoon a smaller number of the visitors went by steam tram to Marchiennes and Dampremy to examine the method of winding from great depths in ten and twelve-decked cages adopted by M. Soupart. The arrangements at these pits were described in M. Briart's paper on "Coal Mining in Belgium," read on the first day of the meeting, and will be found in our report on page 163. A model of the large cage at Marchiennes is shown in the Antwerp Exhibition, where there is also a very fine one of the surface arrangements of No. 5 Bascoup pit.

The principal feature of the forenoon excursion on Friday was the inspection of the Angleur Company's steel works at Sclessin, a smaller detachment of the party visiting the adjoining collieries at Horloz. This company, whose original seat is at Angleur—a short distance from Liége, in the direction of Verviers—purchased the Sclessin works, situated on the left bank of the Meuse opposite to Seraing, in 1892, and has re-arranged them for working the basic Bessemer process, with pig iron smelted from the oolitic ores of Audun le Tiche, in Lorraine. There are two blast furnaces 65½ft. high and 21ft. 4in. diameter in the boshes, supplied with hot blast by four Cowper stoves, of the modified Seraing pattern. The tunnel head gas is taken off by a central tube, and cleaned by passing through large dust catchers before it is admitted to the stoves and boilers. Coke for smelting is made on the ground from the small coal of the neighbouring collieries, partly washed and partly in the rough state, in a battery of 100 Coppée Menier ovens about 30ft. long, 4½ft. high and 17in. wide. The use of such very narrow ovens is rendered necessary by the deficient binding properties of the coal owing to the low proportion of volatile matters present, so that a high heat quickly applied is required to produce a coherent coke. The surplus heat of the ovens is utilised in the firing of seven De Nayer boilers of 200-horse power each, which together with a similar series of Galloway boilers with outside combustion chambers fired by blast furnace gas, supply the whole of the steam for the blast furnace and Bessemer blowing engines. The furnaces are blown by five tuyeres with outside water cooling on the hearth; the principal novelty in their working being the granulation of the cinder which runs continuously into a tank where it meets a current of water flowing in the opposite direction, and is converted into a coarse-grained glassy sand that can be more conveniently lifted by a bucket elevator and loaded on to ordinary railway trucks for removal than the heavy balls or blocks of the ordinary cinder-tub, besides being of a certain value for ballast, building sand, and concrete making. The Bessemer plant, which is very similar in character to that of the newer Westphalian works, comprises three 10-ton basic converters with intermediate transfer and casting ladle cranes, the latter being placed in the centre of a casting pit of large diameter, nearly the whole of which is available for placing ingot moulds, and provided with five ingot cranes. When the visitors arrived the dephosphorising blow of a charge was just completed, and the converter, turned down for sampling the metal, made a very liberal distribution of the slag over the spectators, although separated from them by more than the breadth of the two ladle pits. The slag was received at one end of the transfer crane in a bogie upon a narrow-gauge railway truck, which, when filled, was lifted on to the line by one of the cranes, and drawn away by a locomotive. The finished charge was poured into a ladle on the opposite end of the crane and pushed over to the crane in the casting pit by a horizontal ram in the ordinary way. The ingots, when reheated, were converted into railway sleepers, being rolled down to bars in a three-high mill, cut and stamped in a hydraulic press to a dish shape at one heat, the subsequent operations of bending to gauge and punching the holes for the fang-bolt attachments being done cold. In the latter part of the work a considerable amount of hand labour is required, and in this respect the method of manufacture is in strong contrast to that seen last year at Darlington, where ingots are converted into sleepers, and delivered blacked and finished for shipment with scarcely any intermediate handling. A large and well-arranged puddling forge adjoins the steelworks. This was employed in the production of merchant bar iron, mostly of small sizes. The method of driving the small mills by a belt from the engine, which is directly attached to the roughing train, seems to be very generally adopted. Want of time, however, prevented a fuller investigation of this part of the works, as the hour for the return to Liége had arrived before we were able to reach the furnaces.

On the arrival of the party at Liége they were received at the station by several members of the Société John Cockerill, and proceeded to the Jardin d'Acclimatisation, where luncheon was provided for about 500 guests by the Société. There is in the gardens a great glass pavilion, with one side open to the gardens, and in this the guests were seated, while the Société Royale des Fanfares de Seraing's excellent band, composed exclusively of workmen, played at a little distance among the trees. Nothing was left undone by the hosts to make the luncheon a complete success. At its close a few speeches were made, short and to the point, and then the visitors proceeded to the railway station, where a train was in waiting to convey them to the works. Arrived there, they were divided into separate parties and conveyed from one department to another by carriages and engines borrowed for the purpose from the Liége Steam Tramway Company. Each engine drew one large car, and some amusement was caused by the circumstance that the curves at Seraing being too sharp for the rolling stock, the cars every now and then got off the road; all the passengers turned out, and then six or eight labourers quietly going to one corner first, and then to the other, they lifted the car on to the rails again. The passengers entered and steamed away merrily until the next crossing was reached, when the operation had to be repeated. While on the subject of rolling stock it may be worth while to say that to the train proceeding from Brussels to Liége in the morning an accident occurred precisely similar to that which had happened the day but one before between Brussels and Antwerp. Between Louvain and Tirlemont the train was checked by signals, the driver applied the brake incautiously, and immediatly afterwards the engine and the leading brake van broke away from the rest of the train. No one was hurt on this occasion, and a spare draw-bar being at hand, the delay was brief.

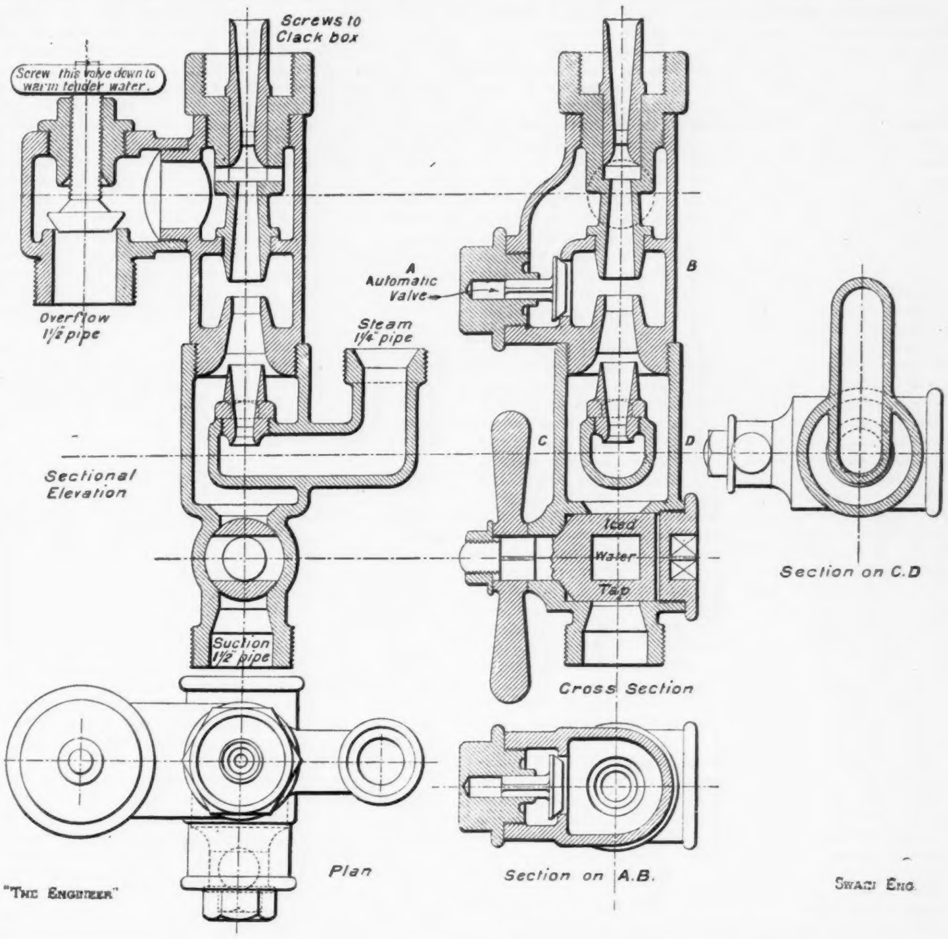
At 2.30 p.m. the inspection of the works began. As the return train for Brussels was to leave at 6 p.m., there was not much time available, and as a matter of fact, the visitors wisely concluding that it would be impossible to see everything, contented themselves with seeing what they could, and found time before the train started to return to the old chateâu, once the palace of the Prince Bishop of Liége. In the gardens they were once more entertained by the Société, and returned to Brussels at a much later hour than was intended, perfectly contented with the day's work.

It would be quite out of the question to attempt to give here any detailed description of these renowned works. It will suffice to say a few words concerning them for the benefit of such of our readers as may not be familiar with the reputation of Seraing. The works were founded by John Cockerill in 1817. They supplied between 1818 and 1823 the first steam engines ever built on the Continent. Between 1823 and 1830 they constructed the first blast engines for ironworks; and in 1824 engines of 160 and 240-horse power for the Royal Marine of the Netherlands. About the same time they made the first exaust fan for a mine, constructed a steamboat for service on the Rhine. In 1835 they made the first locomotive and the first rails produced on the Continent. In 1845 they made the pumping engines for the Paris and St. Germain atmospheric railway. In 1848 they built and engined the first steamboats to ply between Dover and Ostend. In 1854 and 1856 they built three large transatlantic steamships, the Leopold the First, the Duc de Brabant, and the Congres. In 1858 they commenced the construction of the immense plant used in making the Mont Cenis Tunnel. Of their recent work it is unnecessary to speak. It is impossible to overrate the importance of the part which Seraing has played in the development of engineering in all its forms on the Continent; and with engineering the industrial development of the Belgian nation. The progress of the works may be divided into three epochs. The first from 1817 to 1840 when John Cockerill died. The second, the period from the formation of the Société in April, 1842, to 1864. The third period extends from that year to the present time. The first workers with Cockerill were Martin Poncelet, and afterwards Pierre Wery, mechanical engineer. Gustave Pastor in 1817 was director of the Metallurgical Department, and in 1829 he became director of the entire establishment. His connection with the works terminated on the 30th of June, 1866, after thirty-seven years devoted to the extension of the vast concern. From 1866 to the end of October, 1886, Baron Eugene Sadoine was the head of the establishment. From November, 1886, to the 30th June, 1887, the works were managed by M. Delloye-Matthieu, since which time M. Adolphe Grenier has been the head.

The works now cover an area of 267 acres. The nominal capital is 15 millions of francs, or £600,000. About 10,000 hands are employed. The annual wages bill is 9,000,000 francs, or £360,000. There are 355 steam engines developing 19,000-horse power. The coal consumed per day is 1400 tons. The annual output of the establishment is estimated to be worth 35,000,000 francs, or £1,400,000; up to the present Seraing and Hoboken have turned out 69,280 engines and machines, and over 459 ships and steam vessels of various kinds. They can produce each year 100 locomotives, 70 steam engines, 1500 machines more or less heavy; 10,000 tons of bridges, roofs, and boilers; 14 steamships for sea and river traffic, to say nothing of guns, turrets, cranes, and hydraulic machinery. In the shops there are 528 machine tools, many of them of great size and power. The transport service is carried on by eight steamers, of 1400 to 3500 tons, two steam barges, and four barges of 300 tons each, 27 locomotives, 450 wagons. There are thirty-six miles of permanent way. The Société maintains an hospital with 300 beds, and an orphanage, besides schools and gardens, and other institutions calculated to be of benefit to their employés.

The end of the visit to Seraing was also the end of the annual meeting of the Iron and Steel Institute. It was in every respect a great success, and reflects the utmost credit on Mr. Brough, the secretary, and his staff, who indeed worked night and day. The welcome offered by the Belgian ironmasters was extremely cordial. Nothing was lacking indeed but better weather, and that would certainly have been provided by our hosts could it have been obtained by money or solicitation.

## INJECTORS FOR THE L. & N.W.R. LOCOMOTIVE GREATER BRITAIN



"THE ENGINEER" SWAIN ENG

---

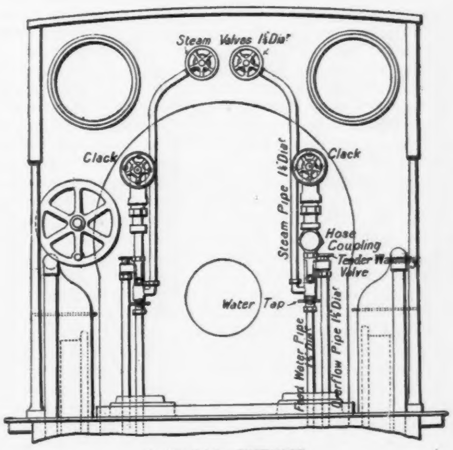
## IRON AND METAL WORK IN WESTERN INDIA.

ACCORDING to a recent report of the United States Consul at Bombay upon "Manufactures of Western India," during the last twenty years the number of ironfoundries and machine shops has greatly increased, and the country is less dependent on Europe for general ironwork. Imports of wrought iron and steel in bars are yearly increasing. Such structures of iron and steel as are made in India comprise:—Barges, bridges, buildings, cotton presses, coasting steamers, grinding mills, hay and other presses, jetties, launches, oil mills, piers, river steamers, sluice gates, small engines, both compound and single, steam boilers, steam pumps, sugar-crushing machinery, tanks, turbines. Railways make their rolling stock, but import axles, tires, wheels, and other ironwork. Rails and steel sleepers, the latter being much in vogue in place of wood, are all imported. Bolt, chain, and rivet making are not yet separate industries. Wire working, being readily taken up by the natives, is steadily increasing. Machine tools are made but in small quantities, most of the tools are imported. Textile machinery is entirely made in England. Agricultural implements are in small demand on account of the ignorance and poverty of the cultivators. Cultivation as practised in Egypt, the grain districts of Southern Europe, and the United States, has not yet commenced in India. The inauguration of systematic cultivation awaits an impulse either from the commercial community, which suffers much from the present degradation of produce, or from the educated native princes, whose revenues would be greatly benefitted thereby. Until this is done agricultural implements can have only a very limited use. The rich native planters recognise that there must soon be a change, and many of them are introducing modern implements. Locks of fairly good quality are made in Bombay and Calcutta, but none of the manufacturers possess a key-cutting machine or a good set of machine tools; their tools are very primitive. Padlocks are the only class of European ironmongery found throughout India; they are used in preference to locks, even on safes and strong boxes. On account of national and religious customs, brass and copper vessels for cooking, drinking, and eating are to be found in every house, and the workers in these metals are more numerous than those in iron. Hollow ware is made of imported sheets hammered into shape, and vessels used for cooking are tinned inside. Brass hinges are made and much used here on account of the destructive effects of the monsoon rains on iron hinges. The whole of the work is done by hand labour without the assistance of a press or stamp. Machinery was tried in a Bombay workshop, but the inferior sheets used would not bear the process and it was consequently abandoned, the experimenter not knowing that better sheets were needed for stamping than for hand work.

## INJECTORS FOR THE GREATER BRITAIN.

THE accompanying engravings illustrate the injectors of Mr. Webb's celebrated locomotive, the Greater Britain, illustrated in our impression for November 20th, 1891. They were made by Messrs. E. H. Birley and Co., Queen's Chambers, Manchester. These injectors are absolutely automatic in re-starting. They have no moving or sliding piece in the nozzles to wear out or stick. They will work in any position, either as lifters or non-lifters. They have a very large range of working pressure; will work hot, and take feed-water when lifting, at over 100 deg. Fah.

The injectors are each No. 8 mm., and at 175 lb. pressure one threw about 1500 gallons per hour into the boiler, being almost sufficient alone to maintain the feed-water at the highest speed of the engine. The injectors were designed to suit the previous standard arrangement of valves, clack boxes &c., on the engines, and have given such satisfaction that this patent is now adopted as the standard injector for the London and North-Western Railway Company's system.



INJECTOR FITTINGS

The modern re-starting automatic injector is now a necessity on locomotives, saving the drivers and stokers endless trouble and worry, as compared with the old Giffard non-automatic injector, which had to be stopped and re-started by hand each time the jet of water was interrupted. Injectors on this patent are made without valves attached, in a simpler form for the ordinary market. The steam pipes for the injectors of the Great Britain are 1¼in. diameter, the overflow 1½in. diameter, the feed suction 1½in. diameter. The valves for warming the tender water are attached—they were made on White's patent.

---

THE Cunard line steamer Lucania passed Daunt's Rock, arrived at Sandy Hook lightship, New York, at 4.59 on the 31st ultimo, having made the passage in 5 days 8 hours 38 minutes, or 51 minutes better than the previous record of the Campania. The average speed of the passage, which was protracted by fog and stormy weather, was 21·65 knots.

## THE FEDERATED INSTITUTION OF MINING ENGINEERS—NEWCASTLE MEETING.

THE annual general meeting of the Federated Institution of Mining Engineers referred to in our issue of the 24th ult. took place in the Wood Memorial Hall of the North of England Institute of Mining and Mechanical Engineers, Newcastle-upon-Tyne, on Wednesday of this week. The continued popularity and appreciation of the Federation was well exhibited by the fact that over 200 members were present at this meeting, in spite of troubled times in certain districts. The first business was the vacation of the chair by the outgoing president, Mr. Arthur Sopwith, and the assumption of the office by the new president, Mr. W. N. Atkinson, one of H.M. Inspectors of Mines. A vote of thanks having been accorded to Mr. Sopwith, the report of the Council was read, in which the increased prosperity of the Institution was alluded to; the membership now being 2068, and the Federation including six societies. The report contained a suggestion that it would be desirable to extend the Federation to all mining and metallurgical societies in the empire, inasmuch as judging from the success of the present Federation of British societies, the suggested Federation could not be otherwise than very advantageous. The papers received during the year included many dealing with geology, mining engineering, mechanical engineering, ventilation, illumination and gas testing, the preparation of minerals, electricity, explosives, and miscellaneous matters. Prizes were awarded to Messrs. Bertrand, Charlton, and Redmayne respectively, for their individual contributions to the Institution's "Transactions," which, owing to their rapid growth, have now to be published in two volumes annually. The first paper read was a contribution from Professor Edward Hull, "On the Discovery of a Concealed Ridge of Supposed Cambrian Rocks under the New Red Sandstone of Netherseal, near Ashby-de-la-Zouch, Leicester." The author based this supposition on the examination of a core obtained in borings recently put down by the Netherseal Colliery Company, and in discussion this occurrence of Cambrian rocks was confirmed by members who had made observations on the surface.

C. A. Stetefeldt, in the second paper considered by the meeting, on "THE STETEFELDT FURNACE," contributed an account of the origin and development of that furnace, which is so well known and largely employed in the Western States. A Gerstenhöfer furnace was started in Austin, Nevada, U.S.A., in 1867, but the shelves proved an obstacle to the roasting of the sticky ores of the district, and, as a result, the author erected a furnace with a plain shaft 25ft. high. With this, however, the Gerstenhöfer feeder—consisting of fluted rollers and an iron plate with narrow slits—proved inefficient for distributing the ore in the furnace, and consequently the author's rocking sieve feeder was devised. Then it was found that much dust escaped from the flue imperfectly roasted, and this led to the introduction of the second fireplace for heating the flue, and known as the auxiliary fireplace. The furnace has from time to time undergone modifications to suit local circumstances, but the main features have always been maintained. A tall, square, tapering shaft, with a descending flue alongside leading to a series of chambers, the last of which connects with a chimney, either direct, or preferably with an intermediate flue following the slope of a hill, where circumstances permit. In the most recent furnaces the shaft is 48ft. long and 4ft. square at the top, 37ft. being the active falling distance. At that distance down the heat is applied, and the furnace is 6ft. square. Some 6ft. lower down there is a hopper, closed by a swing door, in which the falling material is arrested and accumulates; whilst beneath the hopper there is space to permit of a truck running underneath to receive a charge of treated material. The flue commences at the top of the shaft, and descends at an incline alongside of it. Being heated at the same level as the shaft, the chambers and chimney call for no special comment. The Stetefeldt feeder consists of a cast iron grate covered with a steel sheet punched with $\frac{1}{8}$in. holes, through which the ore-pulp, mixed with salt, is fed by the oscillating motion of a wrought iron rocker having a No. 4 wire screen stretched over the frame, the necessary friction being created by stationary blades. The rocker is now suspended by adjustable flexible steel bands instead of being supported on friction rollers as hitherto. The distance of the rocker from the punched plate, and of the fixed blades from the rocking sieve, and the rate of rocking, can be regulated so as to adjust the feed as required. By means of a damper situated below the grating, the feeding appliances can be shut off from the furnace for repairs or other purposes. A bucket elevator conveys the mixture of ore and salt to the top of the furnace. The mixture falls from the feeder down the heated shaft, and in its descent becomes partially roasted and chlorodised; only about 32 per cent. of the roasted ore, however, reaches the hopper, the rest passes into the flue, where it is subjected to a second roasting, and about 55 per cent. of the roasted ore is caught in the hopper below the flue, of the remaining 13 per cent. eleven is caught in the first six chambers and one in the last six. There are various ports placed at convenient spots for inspecting and cleaning any part of the furnace where lodgments may be expected. The firing has until recently been done with solid fuel, but to ensure greater uniformity of temperature, gaseous fuel from a Taylor gas-producer has been applied with great success. For this purpose a spiral-weld steel tube, provided with expansion joints, supplies the gas to cast iron burners, which have openings with covers in the front for cleaning out soot and tar. The gas escapes from the burners through square holes at the top, provided with cast iron slides to regulate the supply of gas, which escapes into the combustion chamber through suitable openings, from which soot can be removed, if it accumulates, through pipes that are ordinarily plugged. Air for combustion ascends through special channels, the supply being regulated by sheet iron slides. It is not necessary to give other details of the furnace. The introduction of gas has effected a saving of 2s. 4d. in one case, and 1s. $8\frac{1}{2}$d. in another case in the cost of fuel for working per ton. The new furnaces have an output of from 70 to 90 tons a day, whilst the output from the old ones rarely exceeded 30 tons. These furnaces are stated to work ore without having it very finely crushed, to occasion very little loss of silver and gold, to consume comparatively little fuel, and to require little labour, only one man per eight-hour shift. Their use has, however, practically been restricted to the chlorodising roasting of ores of the Western States, which consist of galena, zinc blende, fotlore, a little iron pyrites, and a clayey quartz gangue. It is interesting to note that copper, zinc, and aluminium are found chiefly as chlorides, in the roasted ore, in the shaft hopper, but as sulphates in the flue; lead and sodium as sulphates in both cases, but more abundant in the flue. The retaining of the hot ore in the hoppers is very advantageous to the chloridising, the amount of silver converted to chloride produced being largely increased by such treatment.

In discussion it was pointed out that this paper was of value as the only exact account of this furnace. The advantage of using gaseous fuel was also enlarged upon; but the use of this furnace for roasting pyrites was questioned.

John Morison's paper on

"WALLING AND SINKING SIMULTANEOUSLY WITH THE GALLOWAY SCAFFOLD"

deals with an instance where this has been successfully achieved at Newbattle colliery. The success depended largely on the cradle designed and used by the author. It consisted of a working floor and a protecting roof with a central opening admitting of the passage of two kibbles, the opening being fenced by sheet iron $\frac{1}{4}$in. thick and $6\frac{1}{2}$ft. high, bolted to the six upright angle bars and hangers. The floor stage was formed by a 4in. by 4in. by $\frac{1}{2}$in. mild steel angle bar turned to a true circle, supported on and fastened to a bottom framing of 5 by 5 by $\frac{3}{8}$in. steel angle bars. Hinged hatchways, recessed for passing pipes, &c., were provided in the floor so as to permit of passing obstructions and allowing brick kibbles to be lowered if required.

The floor was covered with planking 5in. thick. The roof was formed of 5in. by 5in. by $\frac{3}{8}$in. steel angle bars, covered with $\frac{3}{8}$in. sheet iron plates. The framing of the roof where the suspending wheels carry the whole of the cradle is constructed of double 5in. by 5in. by $\frac{3}{8}$in. steel angle bars riveted together. The bottom and top of the scaffold were connected together by four corner steel angle bars, 5in. by 5in. by $\frac{3}{4}$in., bolted to the top and bottom framing; four stays being placed to the four upright corner angle bars for the purpose of supporting and stiffening the top or roof framing. Two $1\frac{1}{2}$in. tension-rods were secured to the double angle bars and to the outer ring of the floor, for the purpose of strengthening and carrying the floor. A sheet iron ring, formed of $\frac{3}{16}$in. sheet iron, was bolted to the circular framing and formed a fence round the scaffold 18in. high. The difference between the diameter of the pit and the upper side of this ring was about $1\frac{1}{2}$in., or an opening of $\frac{3}{4}$in. existed between the brickwork and the fence. Fending plates were bolted to the bottom of the scaffold, to guide a swinging kibble through the opening in case of accident. The weight of the scaffold was about $8\frac{1}{2}$ tons; and when loaded with bricks, lime, and workmen, the working load was about twenty tons.

The cradle was hung by four 5in. ropes in double purchase, and proper guides and suitable winding arrangements enabled the engines to wind the kibble even 1650ft. in fifty-five seconds. Pulsometers delivered water from the sump to a tank furnished with valves and boggers for running the water into barrels; these arrangements obviated any necessity for baling, and 200 gallons could be wound per minute from a depth of 900ft. while sinking progressed and pumps were fixed.

In walling, a roll of canvas or brattice cloth was packed between the outer ring on the scaffold and the shaft side, so that there was absolutely no opening. The hatch or doorway, where it closed against the air boxes, pipes, &c., was also carefully packed with canvas before commencing to build the walling. Sheet iron plates where laid over the hatchway where the brick kibble was tipped. The bricks and lime were sent down in kibbles provided with trunnions, and the material was tipped without detaching the kibble from the rope. At the top of the pit the empty kibble was landed on to a bogey, detached from the rope, and a full kibble hung on in its place. When walling, three bricklayers with three labourers and a sinker in charge was the most convenient number to work on the scaffold, and in ordinary work these would build a 5ft. length complete. The scaffold was considered safe from damage by shots in the pit bottom when at a distance of 60ft. from the bottom. Crib-beds were laid as the foundation was found suitable, and lifts were taken varying from 90ft. to 240ft.

Pump-rooms and lodgments in the side of the shaft could be formed by taking the scaffold to the point required, without any interruption of the sinking. A lift of concrete coffering, 90ft. high and 28in. thick, was put in from the scaffold very conveniently. The ordinary brickwork was $10\frac{1}{2}$in. thick, and the shaft 20ft. in diameter, and 1650ft. deep, was lined from top to bottom, with the exception of small projections of hard stones under several of the walling crib foundations; in forming a crib bed the sinkers left the stone rough hewn out, leaving the levelling and dressing to be done off the cradle. The advantages observed by the author in the use of the cradle are:—(1) It permits of quick winding with double kibbles with great safety. (2) No time is lost through the sinkers being withdrawn to wall. (3) The brickwork can be better done by skilled bricklayers and at a less cost than by sinkers. (4) In forming any necessary recesses or roads off the shaft side, no delay in sinking need be incurred. (5) The suspension of a substantial structure on the shaft affords a considerable protection to the men working in the pit bottom. With reference to the latter advantage, upon several occasions when material has dropped accidentally down the shaft, it has landed on the roof of the scaffold and caused no damage; and especially when working within a moderate distance from the bottom the protection is of great advantage.

Some members present pointed out that the information in the paper was not as perfect as it should be, the saving in time as compared with the ordinary method of working not being noted; moreover, no note as to the method of ventilating beneath the cradle was supplied, and some other technical points were defectively set forth.

This paper was followed by the discussion of papers announced to be discussed, in which it was incidentally remarked that underground photography had progressed so far, that stereoscopic views of underground workings were now to be obtained. The ever debatable subject of gob-fires also attracted attention. The chief point at issue being whether the moistness of a coal had anything to do with its liability to spontaneous ignition, which seems a point that still remains to be decided; it was suggested that to avoid gob-fires, the best practice was to pack well and remove all slack.

The meeting then adjourned, leaving the following papers to be considered on the reassembling: "Timber Bridges and Viaducts," by Mr. Morgan W. Davies. "Explosions in Novia Scotian Coal Mines," by Edwin Gilpin, jun. "The Shaw Gas Tester for Detecting the Presence and Percentages of Fire-Damp and Choke-Damp in Coal Mines," &c., by Mr. Joseph R. Wilson. Various excursions were arranged for Thursday and Friday, and will receive any notice required subsequently, when the unread papers enumerated above are considered.

## THE CHILIAN CRUISER BLANCO ENCALADA.

As a supplement this week we give an illustration of the powerful Chilian cruiser, Blanco Encalada, built at the Elswick shipyard of Messrs. Sir W. G. Armstrong, Mitchell and Co. In our issue of June 1st and 15th we gave accounts of her gunnery and speed trials, at which she attained such excellent results. Her principal dimensions are as follows:—Length, 370ft.; breadth, 46ft. 6in.; mean draught, 18ft. 6in., and her displacement is 4500 tons. Our illustration is from a photograph taken during the gunnery trials of the vessel.

The armament of the vessel consists of two 8in. breech-loading guns, two 6in. quick-firing guns, twelve 3-pounder quick-fire guns, twelve 1-pounder guns, two Gatling guns, and five torpedo tubes. At the trials all of these guns and torpedo tubes were discharged in various directions, and the guns at extreme elevation and depression, in order to test the structure of the ship, with the result that all the fittings and other parts were shown to be of ample strength and able to stand all the strains to which they might be subject by the firing of the guns in action. The steam trials showed that the vessel could run with forced draught at a speed of 22·78 knots, and that she could run as long as her coal supply lasted, with natural draught, at a speed of 21·75 knots. Her normal supply of coal is 350 tons, but she can carry 900 tons. With her bunkers full, the above speeds would be somewhat reduced; but starting with her full coal supply she could steam at, say, the mean speed, $21\frac{1}{2}$ knots, for eighty-four hours, and would cover a distance of 1800 knots, while at the economical speed of 12 knots she could steam for twenty-eight days, and cover a distance of 8000 knots.

The vessel is sheathed with wood and coppered. She has an inner bottom throughout. She carries the very powerful armament above enumerated. She is one of the fastest cruisers afloat, and these splendid results have been obtained on a displacement of only 4500 tons.

The engines and boilers are by Messrs. Humphrys, of Deptford.

## THE CORROSION OF BOILERS.

IN the *Goldsmith's Journal* has been published a very lucid paper on "The Corrosion of Ships and Boilers," by Mr. Ward. Speaking of zinc, the author says that the proper way to use zinc consists in placing a number of studs in the sides of furnaces and combustion chambers, bolting on to these studs the zinc slabs, which should be about 10in. by 6in. by 1in. It is important to see that the contact surfaces are clean and smooth, and that the nut is screwed up tight to exclude the water. When so applied the protection against corrosion is perfect. He concludes his paper by drawing attention to the chief points which should be attended to by those who have charge of steamships or steam boilers:—

"As to the hull.—If of iron, see that all blisters and rust are removed by chipping, and if of steel the magnetic oxide or mill scale should have been removed before applying the paint. Use paint of a good quality, one that consists of a compound of zinc or lead will be best, because it will be more readily oxidised. See that the surfaces are thoroughly dry before painting, as it is quite usual to see paint put upon ships' hulls when wet.

"As to the boiler (externally).—(1) Keep all seams, joints, and rivets tight and free from leakage. (2) Prevent as far as possible all moisture getting in contact with the plates. (3) At least once a year apply a coat of good paint: red lead and linseed oil being the best for this purpose. (Internally.)—Firstly, select a good cylinder oil where it is impossible to work without one, and only use such as have a vaporising point at a higher temperature than the temperature of the steam at the pressure at which the boiler is to be worked. Do not take the statement given of the vaporising points of these oils for granted, even though it may be a standard brand or make, but see that each particular lot as supplied is equal to the sample which influenced the purchase, as it may be taken for granted that the lowest quality that will be accepted without complaint will be about the highest quality supplied. Under any condition endeavour to keep your boiler water as fresh as possible, and where a fresh water supply cannot be obtained it is desirable to fix some contrivance such as an evaporator to obtain the same; and, lastly, if it is impossible to dispense with the use of sea water, means must be taken to counteract its evil effects, such as those I have endeavoured to show in this paper.

"Under these conditions we should be rewarded by our boilers not being cut off in their prime, but dying of old age."

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Engineers: Mr. Frank C. Allen, to the Haughty; Frederick M. D. Spry, to the Rocket; Thomas S. Guyer, to the Starfish; and John W. Ham to the Achilles; to date September 30th.

### GREAT NORTHERN RAILWAY.—RE-CONSTRUCTION OF A BRIDGE OVER THE DON.

IN our last impression we published four views of the work performed in renewing a Great Northern Railway bridge over the Don, and gave some preliminary particulars. We now complete our illustrations of the works.

The bridge being over a navigable branch of the river Don, there was also the canal traffic to provide for. On account of the limited height from water to rail level, no staging could be erected over the canal. To meet the several requirements of the railway and canal traffic, the following method was adopted. A row of piles 9ft. apart, as shown by the engravings of details on page 211, were driven on each side of the canal and parallel with the face of the two abutments, each pile being driven until it set ½in. under a blow of the ram weighing one ton and falling a height of 12ft.—each pile having a working load of 27 tons. On the head of each pile was fixed a crosshead 4ft. by 14in. square; the crosshead being steadied with brackets placed on each side of the pile head, and all bolted together with 1in. diameter bolts. On these crossheads were placed two longitudinal timbers 14in. square, with bridge rails laid and fixed on the upper surface.

On these rails were placed eight special steel trollys of the pattern shown by detail on page 211 and Fig. 3, four to carry the new bridge, and four for the old one; two hydraulic jacks being carried on each trolly, as no staging could be placed over the canal other than that described. The main girders were put together near the site, and when completed were loaded on two trucks and taken to the site, and there unloaded—Figs. 2, and 4, page 194, and in general arrangement on the plan, and placed on two of the trolleys and moved out to the proper width. This being done, an overhead traveller was fixed on the top of the new main girders, and used for erecting the new cross girders and flooring. When the whole of the new structure was nearly completed, the old girders were temporarily supported as shown on page 211. The bedstones were taken out, redressed, and reset, as owing to the lightness of the original girders, the stones were damaged and loose on their beds from excess of vibration. The ballast for a width of 20ft. sufficient to clear the ends of the new bridge was removed, and the permanent way carried on longitudinal timbers and packings, to enable the space to be cleared quickly during final operations. The hydraulic jacks were then connected in sets of four by tubing, each set being actuated from a pump fixed on trolleys, and shown in Fig. 6. When the work was complete and ready for moving into position, all the apparatus was carefully examined, and the lifting power tested. This proving satisfactory, the day for slewing was appointed; the time being as mentioned above.

At the stated time the rails at the ends of the old girders were removed, and the pressure applied to the pumps, and when lifted a sufficient height, wood blocks were then inserted between the main girders and frame of trolleys, and the whole bridge hauled out by means of two crabs, four men to each crab. This occupied from start to finish twenty-five minutes—Fig. 1.

Fig. 5—PLAN OF BRIDGE STAGING AND TRAVERSING TACKLE

While the old bridge was being moved out the new one was being moved in, also by means of two crabs. As the new one was considerably heavier, the operation was ten minutes longer, or thirty-five minutes. The new bridge was then lowered on to its final bed, the ends ballasted and the rails joined up with those on the new bridge, which had already been laid before

# GREAT NORTHERN RAILWAY BRIDGE OVER THE DON

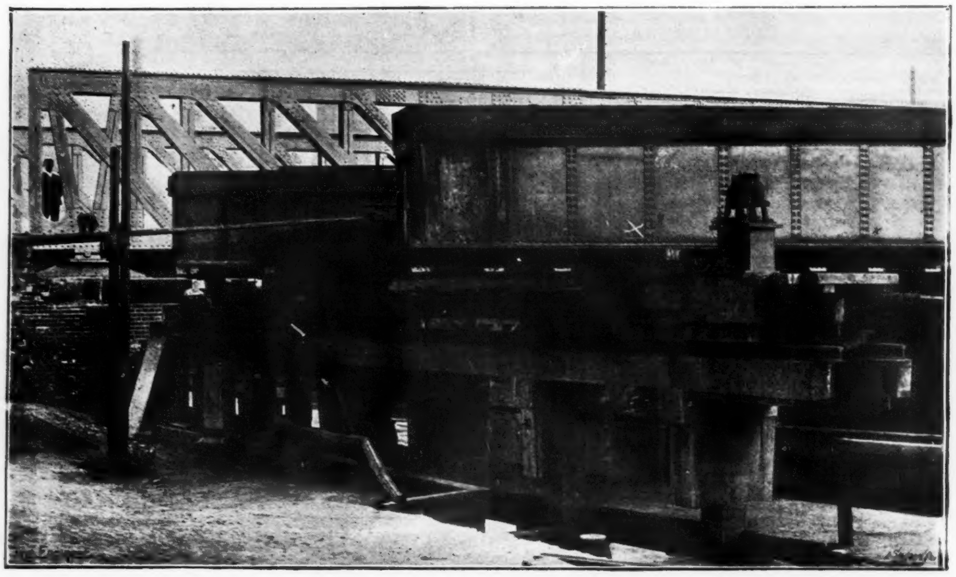

Fig. 6—DETAIL OF STAGING AND PRESSURE PUMPS.

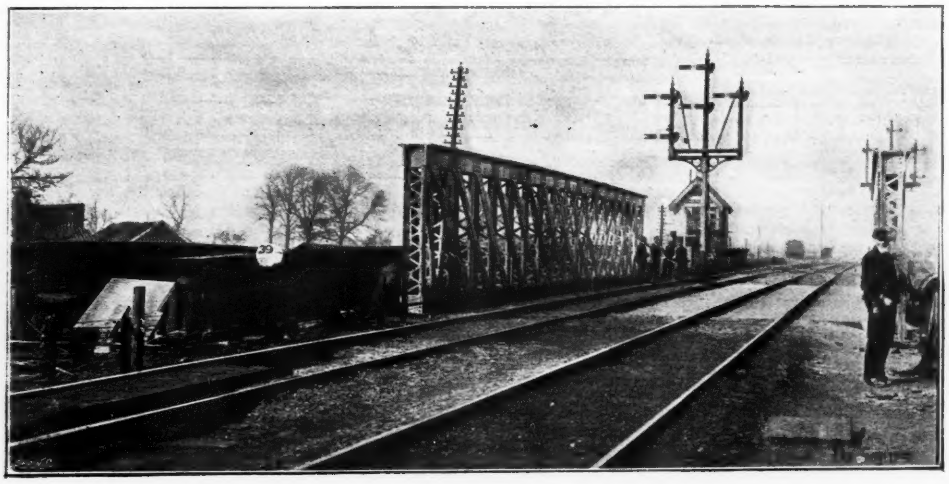

Fig. 7—THE NEW BRIDGE IN WORKING ORDER

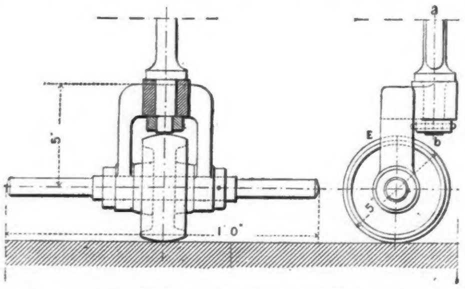
it had been moved—Fig. 5. The whole of the operation, from the breaking of connection until the line was ready for resumption of traffic, was sixty-five minutes, or thirty minutes within the allotted time. The main girders are of the Whipple-Murphy type, and constructed to carry four lines of way. Working details are given by the engravings on page 209, which will explain themselves. The total cost, including taking away the old structure, erection and removal of staging, was £22 per ton of new structure.

## TWO-TON TROLLEY CRANE.

EVERY railway terminal or intermediate station of importance possesses warehouses, stores, or covered sheds for the reception and subsequent delivery or transference of goods, wares, and merchandise. The general arrangement of premises of this description is familiar to most people. A small branch line, or "turn out," enables the wagons to come alongside of the platform or floor of the goods sheds, the level of which is usually so placed as to range flush, or nearly flush, with the bottom of the trucks. In order to facilitate the unloading, reloading, and necessary sorting and shifting about of the different descriptions of goods, cranes fixed and movable, of many various types, are employed. We extract from the "Portefeuille économique des Machines de l'Outillage et des Matériaux" the description and illustration of the most recent form of trolley crane adopted by the Western Railway Company of France. A reference to the accompanying drawing will serve to indicate the general character of this handy little machine. It consists essentially of an inclined beam or jib, which is suspended from a small four-wheel car or trolley at the upper end, and rest at the lower extremity on a small upright post carried by a castor which is free to move in any direction over the floor of the goods shed. The car or trolley runs forwards and backwards between a pair of overhead plate girders, and a lever-arm with a balance weight is attached to the point of suspension or pivot, so as to enable the whole crane to be easily lifted when it becomes necessary to clear bales, packages, or parcels, which always more or less encumber the floor of all warehouses.



TWO-TON CRANE—HEEL CASTOR

*The car or trolley.*—A pair of plate girders shown in elevation in Figs. 1 and 5, and in cross section in Figs. 2 and 6, form the roller path for the car which travels upon the horizontal ribs of the lower angle-irons of the two girders. Each plate girder is built up of a vertical plate web $\frac{3}{16}$in. thick, and an upper and lower angle-iron forming the flanges, 2½in. by 2½in. by ¼in. Inside the web plates the clear width is 9in., and the total breadth over both girders over all, at top, 1ft. 4in. At intervals of every 4ft., the twin girders, which are 1ft. 2in. in total depth, are braced together across the upper flanges by strips of angle-iron 1ft. 11in. long, which together with cranked gusset pieces, also of angle-iron, fasten them to the wooden joists of the building, Figs. 1 and 2. The car itself consists of two pairs of cast iron flanged wheels 10in. in diameter, joined together by a strong bent wrought iron bar or crosshead—Figs. 1, 5, and 6—upon each end of which is fixed the axle of each corresponding pair of wheels. Over the bearings of the crosshead is placed a cup, from which two bent copper tubes supply oil for the lubrication of the journals. Between the pair of wheels of the car, the crane is suspended by an iron rod 1½in. in diameter, turning in the central part of the crosshead B, shown in Figs. 1, 2, 5, and 6. A screw, prevented from becoming loose by two small pins, holds the rod in its place, and two steel washers are placed between the screw and the crosshead, which are capable of sliding slightly upon one another, so as to take the wear off other parts of the machine when it is shifted about. The lower end of the suspension rod is furnished with a staple keyed on to it, and to which is attached the pulley C, carrying the hoisting chain.

*The jib.*—To the jib—which is a "sandwich" beam of timber and iron—is fixed the axis of suspension which passes completely through it. A plank 2½in. thick, secured to two iron plates—4in. by ⅜in.—by bolts, ¾in. diameter and 14in. apart, forms the jib, which carries at the upper end a lever-arm 6ft. in length, supporting at its free extremity a balance weight or cast iron ball 1ft. 2in. in diameter. Two 1in. holes are bored in the ball, through which melted lead can be poured to adjust it when required. Near the top of the jib the timber plank is cut off at K in Fig. 5, and is also discontinued just above the pinion connected with the winch in Fig. 7. The lower part of the jib carrying the hoisting gear is composed of two plates ¼in. in thickness, bolted to the flitch-plates, and also to a stirrup of wrought iron, which latter serves to secure the foot of the crane. In this space of 6in. are placed the principal parts of the hoisting gear, and over all is fixed a covering of sheet iron to protect those working the machine from accidental injury. An iron leg provided with a terminal castor 5in. in diameter, E—Figs. 1 and 2—helps to support the crane in its normal position, and the method of articulation adopted permits the crane to move about freely in every direction. A detail of the arrangement is shown in Figs. 9 and 10, in which the axle of the castor is formed of a wrought iron cross piece 1ft. in total length. Upon the projecting ends of this cross piece, the men working the crane place their feet when turning the handles, so as to keep the jib firm in its place when the crane is under a load. Two iron check plates are attached by bolts ⅜in. in diameter to the lower part of the jib, to guide the hoisting chain and throw it into gear with the pinion—Figs. 7 and 8. There are two axles in the hoisting winch, one carrying the handles or the driving axle, and the other the large wheel which gears into the spur-wheel actuating the chain.

*Power required to work the crane.*—Put P to represent the power, W equal to the weight to be lifted, and T equal to the tension on the chain $= \frac{W}{2}$ all in pounds. Let D = the diameter of the circle described by the two handles of the winch, $D_1$ that of the large wheel, $d$ that of the driving pinion, and $d_1$ that of the spur-wheel carrying the chain, then we shall have the following general equation:—

$$P \times D \times D_1 = T \times d \times d_1$$

or

$$P = \frac{T \times d \times d_1}{D \times D_1}$$

To apply this to the example before us, we have merely to insert the actual values of the quantities. Although the dimensions on the drawings are given in feet and inches, it will be more convenient to use feet and decimals of a foot in calculation. Hence we have for the maximum working load, $W = 2$ tons, $T = \frac{W}{2} = 2240$ lb., $D = 2{\cdot}296$, $D_1 = 0{\cdot}896$, $d = 0{\cdot}232$ and $d_1 = 0{\cdot}273$, and our equation becomes

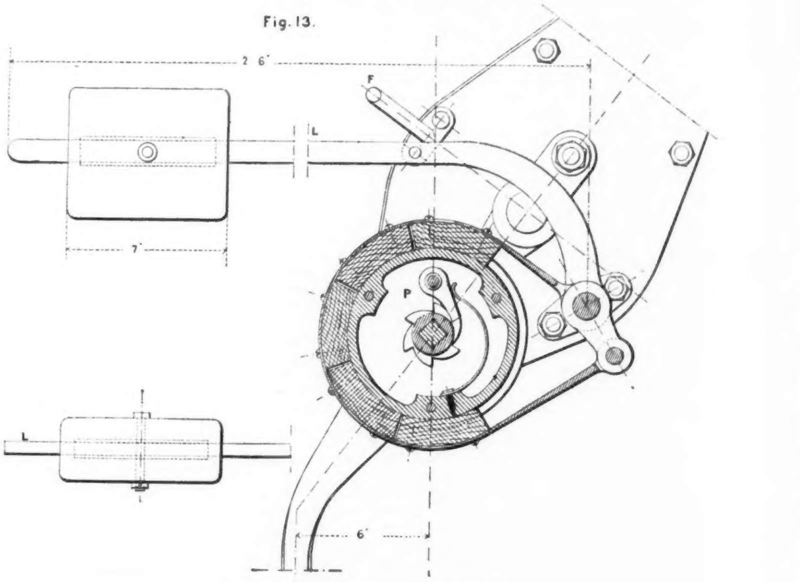
$$P = \frac{2240 \times 0{\cdot}232 \times 0{\cdot}273}{2{\cdot}296 \times 0{\cdot}896} = 68{\cdot}5 \text{ lb.}$$

If we suppose two men to each handle, more particularly as the labour is of a very intermitting character, the effort exerted by each will be 17 lb. The two axles of the winch are supported by bronze sockets fixed to the flitch-plates of the jib by three bolts ¾in. in diameter. Upon the one carrying the chain spur-wheel is keyed the large gear wheel, which has a diameter over all of 1ft., and the other pinion is forged on the axle of the handles—Figs. 7 and 8. In the accompanying table are given particulars, in decimals of a foot, relating to the details of the toothing of the wheel gear:—

| Particulars. | Wheel. | Pinion. |
|---|---|---|
| Diameter at contact .. .. .. | 0·896 .. .. | 0·232 |
| Pitch .. .. .. .. .. .. | 0·103 .. .. | 0·103 |
| Thickness of teeth .. .. .. | 0·049 .. .. | 0·049 |
| Number of teeth .. .. .. | 27 .. .. | 7 |
| Depth of teeth .. .. .. .. | 0·067 .. .. | 0·067 |
| Maximum stress on teeth .. | 682 lb. .. .. | 682 lb. |

The pinion carrying the chain has eight teeth with an external diameter of nearly 4in. and a pitch of 1in., corresponding to that of the hoisting chain. At the end the teeth, which are ¾in. in breadth, are slightly reduced in order to catch the better in between the links of the chain.

Fig. 13.



TWO-TON CRANE—DETAIL OF BRAKE

*Hoisting chain.*—In Figs. 11 and 12 are shown an elevation and section of the hoisting chain belonging to the Galle type, which is composed of links of flat iron 1in. wide and ⅛in. thick, fastened together by pins ⅜in. in diameter, upon which they are articulated. Four links on each side of the chain are held together by the pins, and are kept apart at a uni-

SWAIN ENG

form distance of ⅜in. by a kind of shoulder which slightly increases the thickness of the central part of the pins. A hook attaches the chain at one end to the suspension shackle D—Figs. 1, 4, and 5—and small iron wedges at the other prevent it from becoming disengaged from the small pinion while running out, while the free end runs through a case or box, G, fixed to the under surface of the jib—Figs. 1 and 3. These wedges are held by screws at the end of the chain after its passage over the pulleys, the Galle pinion, and through the box, Figs. 11 and 12. The pulley blocks, including the one C at the top of the jib, are furnished with a central flange ⅝in. wide, to keep the chain in its place. When passing over the top of the pulley C, Figs. 1, 5, and 6, the play of the pins is reduced to ⅛in. by means of a small stud or stop terminating the suspension rod. By this arrangement the chain is prevented from falling in the event of any sudden shock or accident. Both pulley blocks are connected to the hooks by shackles of the same size and shape, and are also both provided with small steel washers to avoid wear between the shackle and the screw nut. Upon the upper surface of the jib is fixed a covering plate K, Fig. 3, of wrought iron, ¼in. in thickness, over which runs the hoisting chain. It is fixed by screws to the timber plank, and the box G consists of wrought iron of the same thickness, bent into the rectangular form shown in the cut. Cast iron sockets M, Figs. 1 and 3, bolted to straps of wrought iron, which are riveted to the iron flitches of the jib, carry the chain box, and the strap N, in the middle of the jib, passes over the chain to keep it in line. A cast iron box, into which is inserted the end of the chain box, protects the lower part of the chain together with the Galle pinion. It also serves as a guide to the chain, and is fixed to the iron plates of the winch by bolts ⅜in. in diameter, in the same manner as the two checks of iron already described.

*Automatic brake.*—An automatic brake, shown in Figs. 1 and 2, and in detail in Figs. 8 and 13, completes the mechanical construction of the trolley crane. It is sufficiently powerful to arrest the fall of the load without requiring any assistance from the handles of the winch. In order to lower the load, all that is necessary to do is to release, by slightly raising it, the lever of the brake L, so as to diminish the friction on the pulley P, and cause the load to descend with the velocity required. If, by any accident, those working the crane are obliged to abandon their hold, the automatic brake will come into play, and maintain the load suspended in the air. It consists essentially of a cast iron pulley P, fixed on the axle of the handles, and a lever counterweight L, actuating a band of iron, upon which are screwed the wedge-shaped pieces of wood which constitute a rim or tyre, nearly surrounding the whole circumference of the pulley, Fig. 13. The lever itself works on a fulcrum, attached to an oval-shaped strap, and the band of the brake terminates in a couple of similar fastenings, one of which is attached to the articulating shaft of the lever and the other to its extremity. The tension on the band is regulated by the cast iron weight situated at the other end of the lever L. It will be seen from Fig. 13 that the brake pulley is composed of two halves, between which is placed a rack to prevent the load from touching the ground, by stopping the revolution of the axle to which the handles are attached. The rack is mounted on the axle, and is furnished with a wheel having six teeth, in which a catch of wrought iron constantly works. This catch is pivoted on a small axle carried by the brake pulley, and is maintained in contact with the teeth of the rack by the pressure of a bent spring, which also prevents it from turning, so as to lower away so long as the pulley is held tight by the action of the balance weight. Three screws, ⅜in. diameter, secure the cover plate over the pulley, and the spring pressing against the catch is fastened to the pulley by a square-headed screw, having a diameter of ¼in. Omitting the plate beams forming the roller path, the total weight of the crane is as follows:—Cast iron, 564 lb.; bronze, 20 lb.; lead, 88 lb.; wrought iron, 598 lb.; steel, 1 lb.; timber, 33 lb.; total, 1304 lb. From the floor level to the soffit of the plate girders is 13ft. 6in., the length of the jib of the crane is 12ft. 7in., and the horizontal radius, or the throw of the jib, 8ft. All these dimensions can be altered to suit the requirements of any particular store or warehouse.

## SWORN'S BOAT PLUG.

The above illustrations show a boat's plug, the patent of Mr. Vincent W. Sworn, of Tunbridge Wells, and which, we think, possesses features which will commend it for adoption for users of boats. Fig. 1 is a sectional elevation when the plug is opened out, and Fig. 2 shows the plug in plan. The plates A and B are made in hard gun-metal, while the actual plug C is made of vulcanised india-rubber secured to the top plate B by means of screw E. The mode of fitting is simply to screw the plate A to bottom plank of boat, which, for this purpose, should be strengthened by fitting the usual thin wood plug cap on the outside of boat. To render the drain-hole D water-tight it is only necessary to turn the top plate B over on to the lower plate A, pass the hinged screw-bolt L into the recess G, and screw the butterfly-nut F down on the top plate B. The plug C thus covers the drain-hole D, and is pressed into same by screwing the butterfly-nut down on to the top plate, thus securing perfect water-tightness of hole; the whole operation taking only a few seconds. To relieve the boat from any accumulation of water when on shore, hanging in the davits, or stowed on a ship's deck, it will be seen that it is only necessary to reverse the operation described. The plugs are used in H.M. Navy, and by many private boat builders, and they are made in three sizes.

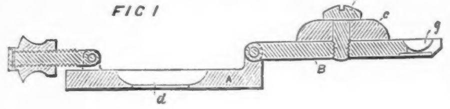

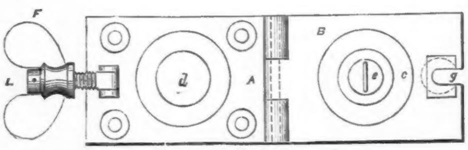

FIG 2

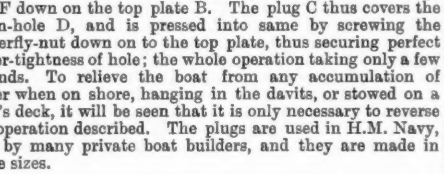
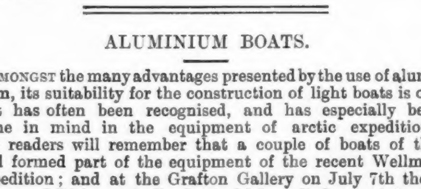
## ALUMINIUM BOATS.

Amongst the many advantages presented by the use of aluminium, its suitability for the construction of light boats is one that has often been recognised, and has especially been borne in mind in the equipment of arctic expeditions. Our readers will remember that a couple of boats of this kind formed part of the equipment of the recent Wellman Expedition; and at the Grafton Gallery on July 7th there was on exhibition a similar boat which excited some interest.

The boat which is shown, holding twelve men, is 18ft. long, 5ft. beam, 2ft. deep, and can carry two tons; and with sails and masts weighs 192 lb. It is built in three sections, as shown. The two end sections are interchangeable, so that the boat may be sailed either way; or if desired the end sections form a complete boat, as shown, in which form, filled with stores, it is designed for their conveyance on sledges across the ice. The whole is covered inside and out with Messrs. Docker Brothers' non-corrosive paint, which is impervious to the action of seawater.





Each section has a waterproof canvas covering stretched tightly over the top, perforated with holes with bag-like fittings for the rowers to draw tightly under their arms, each section thus forming an absolutely watertight compartment. All the metal fittings and wire ropes are of aluminium, and the basketwork fenders, which keep off the floating ice, when not in use fold in the bottom of the boat, are to be used to sleep on, and whilst the middle section forms one sleeping compartment, the others when placed on end and facing one another make a small tent. The bamboo mast is also in two parts, so that it can be stored away when not in use. The cooking utensils are also made of aluminium. The makers are Messrs. Swain and Kirby, of Birmingham.

The new bilge keels which are being fitted to the vessels of the Royal Sovereign class weigh some fifty tons. The fitting of these to each vessel takes about a month to complete. The Repulse has already been dealt with, the Resolution being now in hand.

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### OSCILLATING v. INCLINED PADDLE ENGINES.

Sir,—In reply to "Voyager" I say that in all respects the oscillating paddle engine is superior to the inclined engine. Its weight is less, and in simplicity and cost of upkeep it is much superior. But it has the drawback that it requires a deep boat. The Belgian steamers only draw 8ft. or 9ft. They could not get into Ostend at low water if they were deeper, and oscillating engines cannot be got into this depth without sacrificing all their advantages. The great difficulty of the oscillating engine is the central crank for the air pump. This can be got rid of in various ways. In the Dutch boats there is a large excentric close to the high-pressure cylinder. This works two levers, driving the air, bilge, and feed pumps. The circulating water is provided by a centrifugal. Engines of this type have given every satisfaction. For triple-expansion work the oscillating system does not answer, and nothing better has been devised than Laird's arrangement used in the London and North-Western boats. J. S.

Birkenhead, September 3rd.

### APPROXIMATE CALCULATIONS.

Sir,—How annoying it must be for M. Normand to find British naval architects persistently ignoring his treatise on "Approximate Calculation," published about thirty years ago, and to see some one continually trotting out a formula which is either not as good as his or else exactly the same. The latest sinner in this respect is Mr. Archibald Denny, who at the summer meeting of the Institution of Naval Architects gives a rapid method of calculating wetted surfaces as follows:—$S = L\left\{(D \times 1{\cdot}7) + (B \times C)\right\}$ If in this formula we substitute $(D \times 1{\cdot}5)$ for $(D \times 1{\cdot}7)$ and $C + 0{\cdot}09$ for C we find that it is M. Normand's formula for an approximation to wetted surface, and that it is perfectly unjust to rechristen it Mumford's in 1894.

A perusal of M. Normand's valuable work will evidently be very useful reading for Messrs. Denny's tank staff, as all that can be said on approximate calculation has pretty well been said in it.

Foreigner.

### A NEGLECTED FIELD FOR INVENTORS.

Sir,—The following extract from a letter just received from a friend in Spain may interest your readers:—

"I do not understand why foreign inventors take out so few patents in this country. Spain is not alone the land of wine, fruits, and cigarettes; for with reference to objects manufactured, other articles are used here besides guitars, swords, sashes, arms, and fancy headgears. Not only in Catalonia, that eminently commercial and industrial province, whose inhabitants, exceptionally intelligent and laborious, willingly adopt new systems and apparata as soon as the example is given them, but also in districts such as Bilbao, Valencia, Savilla, Antequera, Bejar, and Alcoy, Spain possesses very important industrial centres. A number of different industries exist in Madrid and its vicinity—the chemical and agricultural enterprises, railways, tramways, electric light, &c., all offer a wide field for inventors. Transactions, they say, are difficult in Spain, and are not well paid, but these difficulties are greatly exaggerated, and as influential English and French agents are to be found in the principal cities of the country, foreign manufacturers can fully ensure protection of their interests. If more attention is paid to this country, I am sure that it will be done at a profit."

Any further information I shall be pleased to supply.

Nottingham, September 5th. H. Walker Hill.

### CUIRASSES.

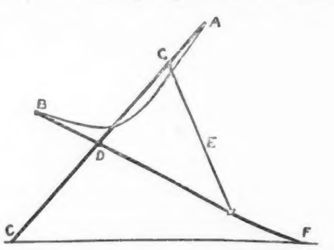
Sir,—I was labouring under the delusion that the cuirass humbug was dead and buried. It seems, however, that I was mistaken. I attempted to show that a piece of good steel accounted for all the phenomena. If the public did not understand me, it certainly was not my fault. I demonstrated that a steel plate weighing no more than 10 lb. to the square foot would stop a Lee-Metford projectile every time with a considerable margin for safety. After this, one would suppose that the cuirass makers would have to beat these figures in order to get any notoriety in the newspapers. The test is an exceedingly easy one. Let the cuirass exhibitor fire a dozen shots at his cuirass; then the area of the field containing these twelve shots could be measured and the cuirass weighed. All the instruments necessary are a carpenter's rule and grocer's scales. Then we should see whether these gentlemen would be able to beat the sheet of steel or not.

The fact is, however, that all these so-called cuirasses are nothing more or less than a piece of armour-plate sewed up in a bag, except those which are made for daggers, when a piece of dried rhinoceros hide answers the purpose admirably.

Bexley, September 5th. Hiram S. Maxim.

### THE GRAPHIC STATICS OF A DECK CHAIR.

Sir,—Just at this season deck chairs form a not inconspicuous object of attention. They are in many ways comforting and restful. But they are more than this, they supply, properly used, a most interesting, instructive, and perplexing subject for the study of the composition and resolution of forces. I give a diagrammatic sketch of one, and I ask any of your readers to determine the stresses at the various joints when a man weighing, say, 160 lb. is seated on the canvas. It will be found that the problem is about as difficult of solution as can be imagined. To begin with, what is the pull of the canvas at the points A and B? Again, A C tends to turn on D as a fulcrum; it is prevented by E, which tends to force F downwards, but the effort at B tends to compensate for this. What is the stress at G? What is the longitudinal or compressive stress in B F tending to cause it to slide back along the floor, and due to the pull of the canvas at B?



I could add half-a-dozen questions, but I think I have said enough to show that this affords a far better example of complicated stresses than did the camp stool, round which raged such a combat a few years ago in the correspondence pages of The Engineer.

Dunoon, September 3rd. Canvas Back.

### LOCOMOTIVE ENGINE BOWS.

Sir,—In dealing with the problem of reducing the air friction and resistance of trains, the experiment of placing "bows" in the front of a locomotive is only a fractional part of a very extensive problem. It has always seemed to me that there must be a great waste of power in creating the draught that is felt when sitting in a railway carriage with one's face to the engine, and travelling at, say, forty miles an hour. Supposing there are eighteen carriages in a train, and each is divided into six compartments, we have 108, into which stationary air is being forced and propelled at the speed of the train.

Again, our English carriages are built with narrow windows, which necessitate numerous projections, which although small when taken in the aggregate, must consume a considerable amount of power to propel them through the air. The underframes of the carriages are constructed in a way that form almost an ideal air trap. The above may seem mere trifles, but Mr. Maxim has just pointed out by his wonderful experiments in connection with mechanical flight, that projections—mere trifles—on the aëroplane of his flying machine meant all the difference between success and failure. The resistance of these is insignificant compared with those in connection with a railway train.

Can the power required to overcome these resistances account for the discrepancies which you have so often pointed out between the theoretical power of a locomotive to haul a given weight of train and that required in actual practice? W. P. Walker.

Beckenham, August 31st.

### THE THEORY OF THE STEAM ENGINE.

Sir,—Mr. Donkin's paper read before the British Association is full of interest. It might have been rendered more valuable, however, by a fuller enunciation of Mr. Donkin's own views. May I ask him to tell me and your readers in general, how he explains such performances as that of the well-known Pawtucket pumping engine, in which admitting steam to the jackets did no good but rather harm. There are dozens of such cases available with all kinds of engines. It is quite clear, indeed, that the factor of condensation in various engines is very different. In fact, in no two engines is it alike. Some light on this point is urgently needed. It would seem, indeed, that we are standing on the very verge of a notable discovery. Why cannot all engines be built so that, like the Pawtucket engine, they can be extremely economical and have no jackets? While I am on the subject I would like, with your permission, to direct attention to another point which wants clearing up. When a gas expands without doing work, its temperature does not fall; were it otherwise the fall in temperature could not be precisely proportional to the amount of work done. The fall in temperature is a result of the doing of work, not of the expansion of the gas, and, accordingly, we can say that $\frac{T - t}{T}$ represents efficiency.

Now, it is also said that in the steam engine its efficiency is to be measured as in any other heat engine, and that the amount of work to be got out of a given weight of steam depends on the difference in its initial and terminal temperatures. This seems to me to be all wrong, save in one sense; that is to say, it is right if we compare one steam engine with another, but it is all wrong if we compare a steam engine with a hot air or gas engine; and for this reason, steam cannot be expanded without falling in temperature, whether it does work during expansion or not. As expansion takes place part of the sensible heat becomes latent; that is to say, it is expended in doing internal work. The external work is done in the case of saturated steam, not by the sensible heat, as is the case with a gas, but by the latent heat. Condensation takes place by the performance of work; but whether little or much steam remains at the end of the stroke, it will have the temperature due to its pressure, no more and no less. The difference then between the action of steam and air or gas is radical, but the fact seems to be constantly overlooked. Until it is fully recognised there will be no good and adequate theory of the steam engine available.

Oldham, Sept. 3rd Maurice Cross.

### THE RAIYAN RESERVOIR AND DRAINAGE CANAL.

Sir,—Although, as was stated in your issue of July 27th, the three Commissioners appointed by the Egyptian Government to advise on the proposals for the regulation of the Nile were unanimous in rejecting the Wadi Raiyan project, this decision is not in any way to be regarded as final. The session of the Commission held on March 27th, 1894, was devoted to the examination of my views. I was asked to explain to the Commissioners the plans which I had recommended for the utilisation of the Wadi Raiyan, to state in what they differed from those submitted by the Department of Public Works, and the objections which, in my opinion, might be made to those presented for the consideration of the Commission. I proceeded to give a summary of my discovery of this depression, citing documentary evidence as to the origin of my own inquiries and the state of the reservoir question from the time of Mehemet Ali down to 1882. I showed that on May 16th, 1881, I had published the expression of a hope that the explorations which I was about to undertake in the Fayoum and adjacent desert, during the following winter, would not only lead to a more intelligent conception of the system of irrigation in force in the brilliant days of Egyptian prosperity, two thousand years ago, but that practical results might also be achieved, and that if this proved to be the case, these researches would "enormously increase the population of Egypt and redeem a large area of so-called desert." The value of a reservoir is now acknowledged. Its annual returns are estimated at between £7,000,000 and £12,000,000.

How is it possible that this immense addition to the wealth of Egypt should have been ignored during that half-century of progress, since the conversion of the Delta from inundated land into irrigated fields under Mehemet Ali, to the arrival in Egypt of the Anglo-Indian engineers? The answer is given in the "Memoires des Principaux Travaux en Egypte," published by Linant de Bellefonds in 1872-3. This great French engineer recognised the value of a reservoir, but the objections to ponding up the water in the valley itself seemed to him insuperable. No dam, of course, could be constructed to the north of the rock, which crops out for the first time across the river bed at Silsileh. Here the sandstone was too unsatisfactory, in his opinion, to permit of more than an elevating dam or barrage, sufficient to raise the low Nile about 20ft. This view was shared by all the European and American engineers in the service of Ismail Pasha, as well as by those who visited Egypt. Their name is legion, and they included the most eminent engineers and contractors in the world. The difficulties were not simply of an engineering character. The problem was for many reasons one of great complexity. Absolute safety, whether from the normal pressure of the water, and the scouring of the silt-charged current, or the exceptional but possible chances of war, anarchy, or earthquake, had to be attained. Such a dam must be as firm as the everlasting hills, and in appearance as well as reality, when the susceptibilities of five million inhabitants have to be considered. The Channel Tunnel is an illustration of the weight of popular apprehension, even when excited by a remote and contingent danger.

In 1881-2 there was a movement in the direction of a reservoir at Silsileh, but it is noteworthy that it was due to a physician—not an engineer—a M. La Motte. It was skilfully used for political purposes by the French Colony; precisely as the abortive scheme of M. Roudaire was countenanced by M. de Lesseps and the French Government, to secure a hold upon Tunis by planning an engineering work which, by flooding the Shotts, would detach Tunis from the African continent and facilitate its annexation to Algeria.

Linant de Bellefonds, having thus rejected a valley reservoir, proposed the construction—or, as he maintained, the re-construction—of a lake on the upper eastern plateau of the Fayoum. It was to contain 2915 million cubic metres of water, and thus be of the same capacity as that now projected at Assouan. Nothing, however, was done by him from 1842 onwards to work out a detailed scheme, and in 1871-2 he obviously considered it as impracticable. Doubtless mature reflection had led him to the conclusions so lucidly stated by Major Brown, Inspector-Genera for Upper Egypt, that such a reservoir would endanger th

Fayoum. I therefore claim that the Silsileh episode would have been long since forgotten had it not been for my persistent and continuous efforts. The acknowledgment, made first in official publications in 1887, and in the Parliamentary Reports of 1890, that the Raiyan depression was a feasible and innocuous mode of draining the basins of Middle Egypt, reducing the danger to the Delta of an excessive flood, and storing a supply sufficient to double the low Nile for the three months of water famine, revived the hopes of the shareholders in the moribund Société du Nil. It is obvious that nothing has occurred to diminish the danger to Egypt from the accidental or wilful destruction of a reservoir dam at any point between Assouan and Halfa. Nor is the sanitary objection to ponding-up the water other than it was in the days of Linant. The control of the whole country is unquestionably given to the masters of the gates through which the river would pass. A section of the river would be depopulated for a hundred miles. It may be argued that these objections are not fatal, and do not justify Linant's conclusion. They have been considered with care by the Reservoir Department, and an opinion expressed. It is certain, however, that a widespread feeling exists—fostered, no doubt with an evident animus, by the archæologists and the native Press—that the military, social, sanitary, and engineering difficulties have been unduly minimised by the English officials in the Public Works Department. It is pointed out that had the Technical Commission authorised the Assouan dam as proposed by Mr. Willcocks, the piers would, according to Sir B. Baker, have been destroyed by erosion; and that the addition of £400,000 worth of cast-iron tubing completely changes the structure in an essential feature. The deposit of silt, also, in the river bed, would commence where the current entered the still reach of the reservoir. When the gates were first lowered, in December or January, the sand would drop just above the sills; but as the river current was checked at a point steadily advancing for three months southward, the deposits would retreat, to advance northward as the lake was lowered. The bed would thus be raised for a hundred miles. The bar formed by the Barrage is noticeable at Roda, south of Cairo. The Philæ bar would extend to Korosko. In order to keep the flood channel clear, the river would be required to take up this matter in addition to what the current already carried in suspension in the flood, and shoot it into the Mediterranean, some 750 miles distant. The scouring of a channel has often disappointed expectations founded on careful observations. Water in movement readily takes up silt, but drops it on the least excuse. In this case it would be difficult to predict with certainty the effect on the flood-Nile. It would make the current at the cataract more impetuous, although some deposit might reduce the strain upon the foundations of the dam. It would level up the floor of the river in the cataracts, and make a bar a short distance below the dam.

It has been calculated that if the dam yielded to a strain, when full, the river bed would carry off the water without endangering the country. The more dangerous moment, however, would seem to be in October. If even a small number of the gates were lowered, or obstructed by floating trees or other material thrown into the river with malicious design, the dam would be overtopped by the flood in a week, even though a relatively large discharge were passing through some of the sluices. As the Nile flows in a deep bed by the side of a long plain which tilts towards the west, any body of water, diverted by a temporary obstruction in its normal course, would never return to the river. It would pursue its destructive career across the fields and villages and be deepest under the foot of the desert hills. Over the sanitary question the doctors differ. I go too far, in the opinion of Rogers Pasha, in considering this alone sufficient to ensure the rejection of a tropical tank, however long, filled with water from the White Nile. Nor does the present chief sanitary official attach importance to the danger of local pollution by cholera or similar disease from the Nubian villages. These are points, nevertheless, that are still being urged with some success, and with a certain amount of support, largely, no doubt, personal, political, and sentimental. On the other hand, confronting all objections to a reservoir, we have a glittering pile of gold in the tempting prospect of immensely increased revenue. As I have elsewhere said, this increase of the summer supply of the Nile is a work which the amelioration of the millions of inhabitants of Egypt demands. It is impossible for England now, with due regard to her Imperial interests and her prestige, to allow those to triumph, whether political rivals or honest but misguided sentimentalists, who are trying with energy and ingenuity to shelve the whole subject.

The archæologists seem to favour a Kalabaha dam, but the Kaibar site has its advocates, especially in military circles, while I am in no way willing to abate my advocacy of my Raiyan scheme. In the last number of the Journal of the Royal Institute of British Architects, I bring the question up again, because no authoritative decision has been reached by Sir B. Baker, M. Boulé, and Sig. Torricelli. There is ample measure of justification for this contention in what took place in the session of the Commission to which I have referred. It will be observed that the technical commissioners were selected by the reservoir department. They were a purely advisory body. They had no authority delegated to them by her Majesty's Government or the other Powers. They were not "International" in any other sense than that of being of three different nationalities. I denied any jurisdiction over me or my scheme. It is evident from the form of the question put to me that this was admitted, and that the Raiyan plans submitted for the consideration of the Commissioners were not mine.

"M. Cope Whitehouse fait remarquer à la Commission que le projet nommé 'The Raiyan Project,' dressé par la direction des Reservoirs, est nullement acceptable. Il la prie de le rejeter comme inadmissible. Il caracterise la carte et la section comme non seulement incompletes, mais aussi pleines de deceptions." Thus I not only denied the competence of the tribunal to sit in judgment on my Raiyan project, but invited the Commissioners to reject that form of the Raiyan project which had been prepared by the Department of reservoir studies, and challenged the accuracy of the map and the alleged facts submitted to them for their guidance. The Commissioners conceded that "le projet de M. Cope Whitehouse est tout-à-fait différent de celui qui a été soumis à la Commission, et qui'il faudrait d'abord en faire l'étude et l'estimation." Thus it must be admitted that so far as my own Raiyan plans are concerned, I have saved my rights whatever they may be.

The Raiyan project submitted to the Commission was disavowed by me, and this was distinctly recognised. My plans were not examined, and no opinion was expressed.

There is one use of the Raiyan depression on which all parties might be disposed to agree. In the volume entitled "The Fayoum and Lake Moeris," Major Brown discusses my proposal to utilise the basin as a waste-weir for the drainage waters of Middle Egypt. "The last use to which the Wadi Raiyan might be put is to adapt it for the reception of the drainage waters of the Nile Valley, after the basin area of Middle Egypt has been converted into Sefi—summer—irrigation by means of the increased supply provided by the assumed existence of reservoirs in the Upper Nile Valley, and a regulating dam at Asyut. When all these basin lands are converted into tracts under perennial irrigation, there will be a great difficulty in the disposal of their drainage water during the time of high flood, and the Wadi Raiyan affords a possible means of solving this problem. Even though the drainage might gain on evaporation, and the Wadi Raiyan become eventually full, its water-surface would be annually so far lowered, by allowing a flow out into the Nile during the summer months, as to prepare the basin for the reception of all the drainage it would be called upon to receive during the next flood season." The drainage level of the cultivated land opposite the proposed cutting into the Raiyan basin is about 26 metres above sea level. The high Nile maximum is officially given at 33 metres. It may be calculated that the Department must provide for drainage into some other channel than the Nile for at least three months. This drainage must provide for the maximum duration of the Nile above R. L. 24·5 at Beni-Suef. The alternative proposed is a drain prolongation of the Bahr Jusuf, 110 kilos. in length, 40 metres bed width, and 4 metres deep, discharging into the Rosetta branch. Its excavation, the syphon under the Rayah Behera, and the improvement of the Bahr Jusuf are estimated by Major Brown to cost £600,000.

It would, however, be a distinct advantage if, during the continuance of the present inundation system, even a part of the water standing in the basins could be let off into the desert to the west. The cutting through the isthmus would be 11½ kilos. in length, with the excavation of 7,592,000 cubic metres of marl, and about 2,486,000 cubic metres of rock, for a canal with a bed width of 40 metres. The total cost would be £E379,000 for the marl, and apparently about £E196,880 for rock, or a total of £600,000. An interest and maintenance charge of even £25,000 per annum would be further reduced, or rather covered, many times over, by the use of this water, in the coarse but valuable crops which could be obtained within the Raiyan area, and the utilisation of my Wadi Lulu as a reservoir for the Gharaq and Western Fayoum districts, and the fisheries.

I have, as is well known, repeatedly offered to purchase the Raiyan depression and cut the isthmus at personal risk, under such conditions of repurchase by the Egyptian Government as would leave those in the construction syndicate reasonable profits. It is difficult to see how there could be any very wide fluctuation in cost, now that the principal facts have been admitted by the Public Works Department. Egypt is an ideal land for excavation. Its equable climate and absence of rainfall reduce the rate of excavation to a certainty. If the benefits of such a canal were fixed at only £300,000 per annum, and responsible English contractors agreed to execute the works, with a right of acquisition by the Egyptian Government at any time, on payment of cost and a fair bonus, it seems as if no tangible reason existed for obstructing, actively or passively, a work which would be a great public benefit, and give profitable employment to British capital.

The reproduction of a portion of Plate XVI. enables any engineer to determine for himself whether the plans, submitted by Mr. Willcocks for the consideration of the Technical Commission conform to the ordinary laws of hydraulics. If it had been desirable to attach the Raiyan reservoir to the low-Nile bed of the river by a single intake-and-discharge canal, it would still be incredible that the best line should not be the shortest distance. The intake, however, is designed to serve as a flood relief. It is to receive a large volume of water of at least 100 million cubic metres daily in the critical fortnight, at the second rise of the Nile in October, when the banks of the Damietta and Rosetta branches of the Nile have been weakened. In every year some 60,000 to 90,000 men are taken from their own fields in the Delta by the so-called Corvée. The repairs of the Barrage largely diminished the clearance of silt from the deep summer canals. It consequently diminished their carrying capacity in flood, and increased the danger of bursting banks during the inundation. Yet this proposed flood intake runs southward against the stream! As an outlet it might be of a reduced capacity. For its discharge would be little more than one-fifth, in any given day, of its maximum intake. Besides this, as I had explained a hundred times to the Ministry of Public Works, the quality and head of the water to be discharged are factors of such great sanitary and commercial value that no one could seriously contemplate running the pure Abyssinian rainfall back into the fetid pool formed by the Barrage in June and July.

The section shows that the maximum high Nile is at reduced level 33. Why was not this line carried across the intervening isthmus into the Raiyan depression? Why is not the minimum level of the outlet similarly marked? As the canal works both ways, why should there be a slope to the west of 1 in 20,000? If the bed is dropped to obtain the required section with less excavation, this reason ceases as soon as the water reaches the depression. The section of a canal is merged in a lake. The Wadi, discovered and surveyed by me in 1886-7, and shown upon my maps of 1887-8 as the Wadi Lulu, would necessarily be filled first. By what possible reasoning was Mr. Wilcocks led to assume that water would not find its own level, and that the surface of this considerable sheet of water would always tilt towards the west? Presumably he imagines that this inclination would persist even during the outflow eastward! The "canal" is elsewhere depicted as a thick black line running down, like a pipe, the sides of this depression and running up again on the western slope. It is not even carried straight across. It meanders like a huge snake, when clearly the distance ought to be measured in a direct line on the surface of the water. But why indicate any canal at all after the contours 33—25 have been reached? This is not a case of rival navigation schemes, in which a lake is to be included, as in the Nicaraguan route as against the Panama. Not only is the canal prolonged for 26 kiloms., but one notes with dismay that the "slope" reappears on the other side of this so-called Wadi "Liernur," as if the discharge from the isthmus canal was comparable to a shot from a gun. Its direction once established the way is to be cleared to the 57th kilometre, where its force is spent. But when the Raiyan Reservoir is discharging water back into the Nile Valley at the 20th kilometre at a reduced level of 24, what will it avail to have the mouth of the canal at R.L. 12?

The isthmus canal is the essential feature in my scheme. It is plain that the geological statement of the existence of "Epsom salts" and "Parisian" limestone is absurd. It is inexplicable that no single boring was carried down to R.L. 25, if there was a sincere desire to place before Sir B. Baker, M. Boulé, and Sig. Torricelli well-established facts. It would have added nothing to the outlay. The mere clerical work involved in these conjectures and inferences as to cost of excavation, slope of sides, and pitching, represents an expenditure far in excess of the few pounds required to take out a proper core. Nor would even this sum have been added to the heavy charges needlessly inflicted upon the Egyptian taxpayers by Mr. Willcocks. I offered to make these borings, and permission was refused. I then offered to pay the Government for any extra work deemed expedient by me, but not considered necessary by its officials. This offer was also rejected.

The Raiyan Project was approved by Colonel Western. It was declared to be feasible by Sir C. Scott-Moncrieff. This was communicated to her Majesty's Government, and to all those interested in Egypt, by Lord Cromer, and the Foreign-office, in numerous official utterances, covering several years of repeated examination and mature consideration. There is no evidence to show why the Public Works Ministry in 1894 reverses decisions of its highest officials arrived at in 1887-8. Something has been said of the material to be excavated on a northern line as softer than that on the southern. No doubt it is frequently better to carry water through a more refractory material, but the "marl" would not change in the distance of a few miles.

A discussion of this point would require a resort to facts not disclosed on Plate XVI. It is my object to show that these plans stand self-condemned. In the technical language of the law I moved the Technical Commission to reject the Raiyan project, as presented by Mr. Willcocks, on his own papers. It was an erroneous and incomplete presentation of the case.

The plate shows that the inundation floods the valley to the West of the Bahr Jusuf. It is of such width as to be readily convertible into a relatively vast flood-feeder of the Raiyan isthmus canal. The Bahr Jusuf itself delivers a perennial supply, with a summer minimum of 1 to 1½ million cubic metres—409 to 713 cubic feet per second. In flood, however, it carries 6½ to 7 million cubic metres—2658 to 2863 cubic feet. It is therefore available as a feeder. Each great basin has its own flood canal, by which immense bodies of water are drawn from the Nile into the enclosed area which it covers. By simple and inexpensive means each of these could be made to do its share of the duty imposed upon the flood-escape and reservoir canal. They would be the natural feeders of the Raiyan Canal.

The total estimate of £1,500,000 being reduced by about £350,000 by the suppression of the inlet canal, and cancelling the absurd charges for a western prolongation beyond contour R.L. 25, the total is less than £700,000, even based upon a compact limestone of Paris, instead of the horizontal strata of the easily worked Egyptian stone. In 1887 I offered to deliver the completed works for £1,000,000. The Public Works Ministry concede that Sir C. Scott-Moncrieff by his ill-omened opposition has cost Egypt upwards of twenty million pounds.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

F. B. (Hull).—*From seventy to ninety revolutions per minute.*

W. J. M. (Walsall).—*We cannot answer the first part of your question. As to the second we do not think that much is to be gained just now by emigrating.*

H. W. H. (Larne).—*Rous-Marten's work cannot be obtained now. We hope to inform you with regard to the Midland locomotives in our next issue.*

### HAUSALTER'S TRAIN SPEED INDICATOR.

*To the Editor of The Engineer.)*

SIR,—Will any reader tell us who are the makers of this apparatus?

September 3rd. G. AND H.

### FRUIT EVAPORATORS.

*(To the Editor of The Engineer.)*

SIR,—I shall be obliged by the address of the makers of evaporators for fruit drying. CHELSTON.

September 3rd.

### COCOANUT MACHINERY.

*(To the Editor of The Engineer.)*

SIR,—I shall be obliged to anyone who will give me the address of a firm making machinery for husking and cutting cocoanuts by manual labour or by steam. KERNEL.

September 4th.

### CANDLE-MAKING MACHINERY.

*(To the Editor of The Engineer.)*

SIR,—Can any of your readers oblige me with the name and address of makers of candle-making machinery for making, say, 5000 to 10,000 candles daily from animal fat? VIADUCT.

September 4th.

### HELICAL *versus* STRAIGHT GEAR.

*(To the Editor of The Engineer.)*

SIR,—We have a rolling mill with straight gear, 1¼in. pitch, 4in. wide, but owing to complaints of lines showing across the paper after being rolled we substituted machine-cut helical gear, 1in. pitch, 4in. wide, and these do the work splendidly, but we have broken them twice in a very short time. Is the failure due to reducing the pitch from 1¼in. to 1in., or do helical wheels require to be so much wider and stronger to do the same work as straight gear, owing to the side thrust on them; and about how much greater is the loss of power in helical gear than straight gear?

September 4th. F. G. W.

### SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

| | |
|---|---|
| *Half-yearly (including double number)* .. .. | £0 14s. 6d. |
| *Yearly (including two double numbers)* .. .. | £1 9s. 0d. |

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* THE ENGINEER *is registered for transmission abroad.*

*A complete set of* THE ENGINEER *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

| | |
|---|---|
| THIN PAPER COPIES— | |
| *Half-yearly* | £0 18s. 0d. |
| *Yearly* | £1 16s. 0d. |
| THICK PAPER COPIES— | |
| *Half-yearly* | £1 0s. 3d. |
| *Yearly* | £2 0s. 6d. |

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* THE ENGINEER.

# THE ENGINEER.

*SEPTEMBER* 7, 1894.

### LABOUR AND WAGES IN BELGIUM.

IN our last impression we reproduced certain opinions expressed by an influential member of the Iron and Steel Institute who had visited Belgium last month. It will be remembered that he named the low wages paid to Belgian workmen as a noteworthy factor in the competition of that country with this. The proposition is one of such transcendant importance that it deserves very careful examination. We may, to consolidate ideas, put it into the shape of two questions. In the first place, Is the Belgian iron trade a greater success than the English iron trade? In the second place, assuming that the answer is in the affirmative, is its success due to difference in wages paid in this country and in Belgium?

If our readers will turn week by week to the "Notes from Germany," published with our other trade letters, they will find much valuable information as to the position and prospects of the Belgian iron and steel trade; and they will also find that it rises and falls, is good and bad, very much as our own trade fluctuates. They have in Belgium slack times and periods of hardship just as we have; and we venture to think that no one in this country will say that in Belgium trade is very much better than it is here. If we look for the fortunes made by individual Belgian ironmasters we find that they are few and far between; and in scarcely any case will they compare favourably with those which have been made in this country by such men, for example, as the late Earl Dudley. The great companies do not pay their shareholders any extraordinary dividends. Indeed, taking all the circumstances into consideration, we are disposed to say that making iron and steel in Belgium is not on the whole so profitable a business as making them in Great Britain. Indeed, the conditions of trade are so much alike in the two countries that if an English and Belgian company exchanged mills and furnaces, the change would scarcely be felt as far as buying and selling are concerned. Dowlais, for example, has no more to fear from the competition of Angleur, let us say, than it has from that of Consett. Probably not so much.

But for the sake of argument let us take it for granted that the Belgian ironmaster does make more money than his English competitor, and proceed to consider how far the question of wages affects this. Again, for argument sake, we shall assume that Belgian wages are two-thirds of English wages; or allowing for longer hours, then they are nominally one-half. In dealing with this question, the proper way to proceed is not to consider what the wages paid per man per day may be, but what is the sum represented by each ton of steel or iron turned out. In a word, what is the cost in wages of a ton of metal? Of course it is not necessary as we are considering wages only, to enter upon any discussion of the relative merits of Belgian coal and coke and ore, and methods of working as compared with the same things English. We are discussing wages, or, to speak more accurately, the cost of labour. Now, in order that the contention that labour is cheaper in Belgium than it is in this country may be proved, it is essential that the work done in return for 4s. in Belgium shall be about equal to the work done in this country for 6s. Here, we believe, the whole theory breaks down. Not so much because the Belgian workman is inferior in skill to the English workman, as because more hands are employed. Machinery is not used to save labour to the same extent as it is in this country; a notable illustration of this is supplied by the manufacture of sleepers, referred to in another page. We have very good reason to believe that the actual sum disbursed in wages, or its equivalent, per ton of finished iron or steel is not much less in Belgium than it is here. That it is a little less is certain; but if it were not so it would be impossible for the Belgian or, indeed, the French or German ironmaster to live. In this country we have to pay a very small sum for the support of our army and navy as compared with the national income. On the Continent, as is well known, enormous armies are kept up, and these are paid for by correspondingly heavy taxes—taxes heavy to a degree of which the Englishman has no adequate conception. But besides these, it must always be borne in mind that the great iron and steel works of Belgium do a great deal more for their hands than pay them wages. Nominally the wages are very small, but let us consider all that goes with them. Let us take, for example, the works of Marcinelle and Couillet, of which we gave a brief description in our last issue. As far back as 1836 the company began to build houses for its workmen. There are in all now six groups comprising 160 houses. Each is let separately to one family, and contains all the rooms and offices considered in Belgium as necessary to one family. The rent is 16f. or 17f. a month, or £8 a year. The rent is deducted from the wages paid to the men. The taxes are paid by the company, by which also the houses are whitewashed and kept in excellent repair. In order to encourage the men to save, in 1866 the company began building houses, at a cost of 1734f., or nearly £70 each. These cottages have each a plot of land attached costing 300f. This house can be brought outright in eight years, with its plot of land, by paying down when the contract is signed 407f., and each fortnight in the first year 11·19f., in the second year 10·85f., in the third 10·51f., and so on a descending scale until the eighth year, when the payment is 8 81f. per fortnight. In the same way a better class of house can be had for a little less than 3000f., or £120. The house of the type of 2034·90f. is composed:—(1) Of a cellar 1·90 metres high, divided into two compartments. (2) Of a ground floor divided into two rooms, 5 metres long by 2·90 metres wide, the other 5 metres long by 4·40 metres. (3) A large box room. The house of the type of 2998·80f. is composed of:—(1) A cellar 1·90 metres high, divided into two compartments. (2) A ground floor divided into two rooms, measuring the one 4·60 metres long by 4·40 metres wide, the other 4 40 metres by 3·50 metres. (3) A first floor of three rooms measuring respectively—4·40 metres by 3 metres; 3·20 metres by 2·30 metres; 3·20 metres by 2·80 metres. (4) A large lumber or box room. These houses are very highly prized by the workmen, and only those who know the perfection to which farming is carried in Belgium can realise how great a boon is the plot of land. It is much more than doubtful if the company realises a farthing of profit, although nominally a profit of 4 per cent. seems to be charged. Then there are the schools, which are of three kinds, the infant, the elementary, and the adult. There are, besides, a music school, a drawing school, a school for apprentices, and a housewifery school. All these are free, the cost being defrayed by the company. The housewifery school deserves special mention. It was established in 1871, and gives the girls all the necessary instructions to make good housekeepers. In order to be admitted to the school they must pass an examination in writing, reading, and arithmetic. They are taught sewing by hand and by machine, mending, washing, ironing, cleaning kitchen utensils, cooking vegetables and meat, making soups, making bread and butter—in fact, they are initiated into all the cares and occupations which are necessary in a well-kept household. At the same time they receive a sound and moral education. They become women of order, and will be able to educate their families in the sentiments of duty and principles of economy. More than five hundred pupils have been educated at this school. The Société also subsidises a similar school in Marcinelle.

In 1867 the company decided to come to the assistance of its workpeople by buying flour wholesale and selling it cost price to the men in advance of their wages. In this country such a transaction would be a breach of the Truck Act, but in Belgium it has worked with the utmost success. The regulations are very strict, and no man is compelled to take flour instead of wages. The price is advertised every fortnight when the distribution takes place. The price is generally 3f. to 5f. per 100 kilos. below the retail or shop price. The quantity sold to each family must not be more than it can consume to prevent reselling. The distribution of flour began on the 1st of February, 1867, and up to the 30th of June in the present year 3020 tons had been sold at an average of 4f. per 100 kilos. under shop rates. The workmen have thus derived an advantage of 1,200,000f., or about £48,000. There is also a public bakery, whence the unmarried hands can obtain all the bread they need at cost price. In winter excellent soup is distributed. Again, there is an insurance fund against accident and old age, largely subsidised by the company. The coal mines of Marcinelle are aided by the Provident Fund of Charleroi. No deduction is made from the wages of the men, but the company pays 1½ per cent. on the paid wages into this fund. The coal mines have besides a special accident fund, to which the company as well as the employés and men contribute. This fund provides gratuitous medical assistance to the employés, men and their families, within a certain distance. In 1847 the company erected a hospital in Couillet to receive workmen who have been wounded in the metallurgical works or the coal mines. The hospital is attended to by Sisters of Charity. There are two wards, one for men, containing fourteen beds, one for women, containing three beds, a refectory, bath room, gardens, &c. A surgery and dispensary adjoin the hospital. Every day from 10 to 11 o'clock a.m. the workmen and their families, as well as the workmen who have been slightly wounded and live at home, receive the advice and care of the doctors attached to the company. The workmen who are ill, and the members of their families who cannot come to the surgery, are visited at their homes by the doctors, and receive gratuitous advice and medicine. The sanitary service is divided into nine circumscriptions, each attended to by a doctor residing in the locality. Each circumscription has a radius of about two miles round the respective works.

In endeavouring to form an idea of the relative cost of wages in different countries it is important to take such facts as those we have given into consideration. It is evident that the workmen at Couillet—and Couillet is by no means exceptional—possess advantages of various types, which represent the value of a considerable addition to their wages. No doubt they are really better off in some respects at 4s. a day than the English workman at 6s. a day. It is only necessary to see the men, their wives, and children to realise this; and, furthermore, it must not be forgotten that the drink bill of the Belgian workman is very much smaller than that of his English competitor. But all this does not directly affect the cost of iron or steel, although indirectly it has a very considerable influence. In this country strikes are constantly taking place. Now, like everything else, a strike represents a pecuniary value. The cost of a strike it can very easily be shown must always in the long run be charged against the product. Thus the strike going on in Scotland must affect the value of coal for a long time to come. In the case of a blast furnace, for example, it is evident that the cost of producing a ton of iron, if we take three years into consideration, will be less if the furnace runs continuously than it will be if strikes interrupt operations for a greater or shorter time. In this country there is an idea that the beginning and end of all things with the working man is to pay him money for work done. It is here that Belgium has the advantage. All the employés are given an interest, not in the profits—profit-sharing, often tried in this country, is a hopeless failure—but in their position. They get more than money. The result is that strikes have hitherto been few and far between, and that the strikes which have upset the Belgian coalfields have occurred at places where only money is given, and they have been largely political in their nature. The lesson, we think, to be learned from Belgium, is that the employers in this country should not rest content with paying money, but should give their hands besides solid advantages which will bind them to the place of their employment. In our own Government factories we seldom, if ever, hear of a strike. What may be termed the local advantages are too obvious to be lightly sacrificed. We do not think that we have any reason to dread Belgian competition on the score of wages. The Belgian workman does not turn out as much as the Englishman, but there is none the less much to be learned by those who choose concerning the harmonious relations which should exist between labour and capital. Monometallism is held to be a good thing in coinage; but in the conduct of business between capital and labour it is a mistake to assume that the only means of trading is gold.

### THE SUPER-SATURATION OF SEWAGE FARMS.

THE subject above named was warmly discussed in our columns some fourteen years back. What then gave rise to its ventilation was the death of a gentleman, the brother of a well-known M.P., that was alleged to have been due to the inhalation of noxious vapour arising from a sewage farm across which he had been shooting. The contention of that correspondence was that when sewage is applied to soil in excess of the power of the vegetation upon it, and of the soil itself, healthily to absorb it, the surplus constituents passed off into the atmosphere in a form analogous to sewer gas, and with an effect as likely to prove as deleterious as is that gas when confined in a sewer.

We refer again to this subject because statements recently made in the House of Commons with regard to the condition of the sewage farm at Aldershot would seem to bear out the contention to which we have above referred. We are not aware if any deaths that may have taken place in our great military camp have been traced to the effects of the state of things described as existing; but it must be evident, if this be as bad as has been officially admitted, it will be singular indeed if some mortality among our soldiers might not be traceable to it. Reference may be usefully made here to the description given in the House of Commons of the present condition of this sewage farm at Aldershot. The detail is derived, it appears, from a report made by the medical officer of Surrey. It describes the so-called farm as being more properly to be termed a "sewage marsh." Pools of stagnant, putrid sewage are said in this report to give rise to poisonous exhalations, and we can readily understand why, upon the basis of that report, the War-office has under consideration the future disposal of this sewage at a place sufficiently remote from habitations. For many years past the erection of these in the vicinity of the camp has been steadily increasing, and no doubt the aggregation of population, apart from the military denizens of the camp itself, has become too much for the capacity of the farm, as originally calculated upon, to bear. It has become, in the words of one of our former correspondents, super-saturated. The area of vegetation is now too limited fully to take up the constituents of the sewage discharged upon the land, and the noxious surplus remains unassimilated either by the soil or by the vegetation. It produces in the "pools of stagnant, putrid sewage" remarked upon in the report. One of those who at the time of the correspondence named favoured us with their views, seemed to contend that it was impossible to pass the boundary of assimilative power. It is evident, however, from the facts now made known to us, that the capacity for this has been passed in the case of this Aldershot sewage farm. The correspondent referred to seemed to hold the opinion that excess of sewage would soon find its way, either downwards or laterally, and must so obtain the required deoderisation. Evidently he was mistaken as to this. Once a certain degree of saturation is obtained, fluidities can no longer maintain their flow. The soil becomes waterproofed, so to speak, after it has absorbed a fixed standard of moisture, and holds further additions to this upon its surface in a liquid state until it is evaporated by atmospheric operations. It is on this principle, no doubt, that the advocates of the dry earth system insist so strongly on the necessity for the employment of absolutely dry material. We presume that it is now fully acknowledged that plant life can only absorb the constituents of sewage up to the point at which the healthiness of its development can be maintained. Fourteen years back, when the correspondence we have named appeared in this journal, this conclusion was disputed. It seemed to be then thought that the vitality of vegetable growths could be stimulated until these assumed almost Brobdignagian proportions. We know that, relatively speaking, this has been attained with the production on certain sewage farms; but it has become also evident that this development cannot be urged beyond certain limits. The plants, it is now known, cannot attain growth in full proportion to the amount of stimulant applied to them. When that is in excess of that power, assimilation ceases and rejection begins. Necessarily, therefore, if the already saturated soil in which these plants have their growth cannot, for the reasons above stated, allow the excess to flow into and through it to fresh and virgin soil, the impurities must remain upon the surface after the fashion indicated in the report from which we have quoted.

We should presume, from the intention expressed by the War-office authorities to remove the sewage farm to some more distant locality, that no land remains available near the site of the existing farm for the extension of its area. This is the danger that we think must attend all endeavours to apply this system of sewage disposal. It must always be difficult—sometimes, we should think, wholly impossible—to provide in advance against the increase of population and the corresponding requirements in the extent of the lands for treating the sewage arising from it. Experience has not yet been had as to the length of time that would be required in the case of a super-saturated farm to restore its absorbent power by abstention from sewage treatment. If this could be estimated, it would seem desirable to provide two disposing grounds, each of an area and capacity to serve while one of them might be undergoing the necessary period of rest. This point, so far as is known to us, has never yet been considered, or the dual system involved under it adopted. The disposal of sewage by these farms is, however, too valuable in principle to be lightly abandoned; and the difficulties and dangers which we fear must be admitted to attend it might be obviated could provision be made in all cases of its adoption for the period of rest and de-saturation we have suggested. But we certainly should deprecate any experimenting with such a course in the near neighbourhood of so densely-populated an area as is the Aldershot Camp and its environs. The sooner the possible plague spot is wholly abandoned the better it will be for the health of our valued soldiery.

◆

### SCOTCH RAILWAYS AND THE STRIKE.

THE effect of the strike of the Scotch miners is only partly shown in the accounts of the railway companies for the last half-year. But on the Glasgow and South-Western it was marked by a decrease of some £5181 in the receipts from minerals, though that is, as far as the gross traffic is concerned, more than made up for by increased passenger revenue. On the other hand, there is a decrease in the expenditure, as was to have been expected, though it does not appear in all departments. The train mileage run shows a considerable decrease in that of the goods and mineral trains; but although this is the case, the expenditure for coal and coke for locomotive power is greatly increased—the sum paid being £9000 more—but whether this is due to any stocking of coal, or to the paying of a higher price, remains to be told at the annual meeting. In other items, such as that of repairs and renewals of carriages and wagons, there is a decrease; there are savings in compensation also, but the general charges are again increased. On the whole the position may be best put thus:—Despite the savings we have spoken of and slight increase in the receipts, the proportion of the expenditure to the receipts rose from 51·48 per cent. in the corresponding half of the past year to 52·12 per cent. for the half-year now being reported on. The chief item causing that increase was that of locomotive power, which took a year ago 13·99 per cent. of the gross receipts, and has for the past half-year taken 14·91 per cent. In another way it may be put that a year ago the cost of locomotive power was 7·32d. per train mile, whilst this year it is reported as 8·08d. per train mile. In neither half-year are the working expenses of the steamboats owned by the company included in either the percentage statement or the mileage cost. Already, therefore, the cost of the strike has been in part felt on the railways, and looking at the fact that there is now a daily increase in the number of the miners at work, it may be hoped that its fullest effects are now experienced. It is evident that the railway companies suffer most keenly by these strikes; their earnings are reduced, and their expenses for fuel are increased, for the diminution in the mileage run is not sufficient to counterbalance the additional expenses incurred in bringing coal from other coalfields; whilst the lessened earnings of the workmen are speedily reflected in reduced takings both for goods and passengers, and the purchasing power of the affected district is made less for some considerable time. Possibly the wants of the district may have accumulated in the period of the strike, and thus its conclusion may be followed by a period of greater activity in the autumn and winter than might have otherwise been the case; but the general results of the stoppage are most hurtful to the railway companies.

### CONCILIATION AT WORK.

THE Coal Trade Conciliation Board is slowly but surely justifying its creation. One difficulty after another is being met and overcome. The latest was that caused by the action of the pit lads and surface men. It was not unreasonably urged by the youths employed in the workings, as well as by the adults engaged on the banks, that it was unreasonable to ask them to concede a ten per cent. reduction. Their argument was the strong one that they could not return that which they had never got. The reasonableness of this view appears to have struck both sides of the Board, the members of which, after a long discussion, arrived at an agreement which has an equitable look commending itself to impartial spectators. The substance of the settlement is that the topmen who have received the same advances as the miners are to submit to the same reduction—10 per cent. At the collieries, where the advances have not been so great, the reduction is to be one-fourth *pro rata* on the advances received since 1888. No more satisfactory arrangement could have been made. It means, in brief, that where no benefit was obtained no sacrifice is required, and where benefit *was* obtained the concession is to be restricted to the fourth part of that enjoyed. That is a fair and common-sense arrangement, and should lead to an immediate termination of the strife at the collieries where the practical protests of boys and banksmen have caused work to cease. It is clear that the Conciliation Board, if loyally and firmly conducted as in this instance, is bound to be a power for years in the coal industry of England.

## LITERATURE.

*The Centrifugal Pump. Turbines and Water Motors, including the Theory and Practice of Hydraulics.* By CHAS. H. INNES, M.A. Manchester: The Technical Publishing Company; and London, John Heywood. 1894.

THE latter part of the title of this little book is too broad, as the theory and practice of hydraulics as herein treated relate only to pumps and water motors, while this title would cover the branches of hydraulic engineering which are as far removed from the construction of pumps and motors as the latter is from the work of the master plumber who styles himself hydraulic engineer. It is a useful little book, which sticks to its text, and commences with the simple parts of the theory of hydraulics, as far as is necessary in the problems which present themselves in the construction and designs of different forms of apparatus worked by water under pressure, which lift water by means of pressure artificially created. Commencing with motion of water under pressure, the measurement of flow and power of a stream, loss of energy by friction and change of direction, the author deals with hydraulic engines. These various questions are treated almost entirely by means of simple equations and arithmetic, without in any way lessening the value of the book as a guide on its subjects.

The engines are illustrated by sectional drawings, more of the diagram order than the finished drawing. But there are some forms of hydraulic motors which he has not noticed, such as Rigg's high-speed water engines. In his treatment of the turbines of various kinds he has omitted to mention one of the most important, namely, the Pelton wheel. Those who have wanted a simple treatment of the theory of design of centrifugal pumps and turbines will welcome this little book, and we can recommend it, although there are several subjects and examples of each of the classes of apparatus which should be included to make it complete, and could be incorporated without adding many pages to it. In some respects the book is up-to-date, as, for instance, it gives drawings and plans of the turbine wheels designed for the Niagara water-power works. The cuts might be better, and an index would be useful. There is what is nominally an index.

---

*Yof-Dakar Underground Cables. Report on Repairs.* By CHARLES BRIGHT, Assoc. Memb. Inst. C.E., M.I.E.E. 1893.

THIS is a little book of 108 pages, illustrated by maps and diagrams. It is a somewhat wordy account of certain repairs carried out in a tropical climate, and the edges are gilt. Mr. Bright is very careful to tell us that he taught his subordinates at the outset to be as polite as possible "to all Frenchmen and French-speaking niggers," but to "carefully avoid being too friendly with English-speaking niggers." The book is largely taken up with criticisms on the methods of those who laid the cables. These people would, no doubt, have something to say on their side of the question.

The general scientific value of the work may be summed up by saying that gutta-percha seems to be a bad insulator in hot climates, and that when it is used the cables should be buried pretty deep; that white ants eat wooden things, and that it is not advisable to go out in the sun without a helmet.

The most useful portion of the book is the summary beginning on page 69. This contains a good many recommendations which are apparently the result of Mr. Bright's experiences with the Yof-Dakar cables. As, for example, "A cable with a first-class vulcanised india-rubber core is, as a rule, on the whole more suitable for land line work than a cable insulated with gutta-percha, unless it has to pass through a permanently wet ground, below the surface of which the cable is sure always to remain." No doubt many men employed in tropical cable laying will find much in the book to interest them. It is to be regretted that no light whatever is thrown on the causes which led up to the defects which Mr. Bright had to make good. Were they due to incompetence on the part of those who laid the cables in the first instance or to want of money? Mr. Bright is not to blame for his silence on this point, because he seems to have been told nothing about the history of the line, and did not know whether it was an old cable relaid or a new cable.

---

*Metal Working for Amateurs.* "Amateur Practical Aid" Series. "Brazing and Soldering," by G. EDWINSON; "Gas-fitting," by E. W. DENNISS; and "Brass Casting at Home," by F. J. DURRANCE. London: Ward, Lock, and Bowden. 1894.

THERE are not very many of the numerous books avowedly written for amateurs which are of much use to them, but they may try this little book, and learn from it how to do many of the things that are useful and necessary in model making and other work.

## *BOOKS RECEIVED.*

*Transactions of the Institution of Naval Architects, vol. xxxv.* Edited by George Holmes. London: Office, 5, Adelphi-terrace, W.C. Sold by Henry Sotheran and Company.

*Transactions of the Society of Naval Architects and Marine Engineers, vol. i.*, 1893. Edited by the Secretary. New York, U.S.A.: 12, West 31st-street. London: The International News Company.

*The Sanitary Arrangement of Dwelling-houses.* A handbook for householders and owners of houses. By A. J. Wallis-Tayler, C.E., Assoc. M. Inst. C.E. London: Crosby Lockwood and Son. 1894.

*Coal Dust an Explosive Agent, as shown by an Examination of the Camerton Explosion.* With seven plates. By Donald M. D. Stuart, F.G.S. London: Office of the *Colliery Manager*; E. and F. N. Spon.

*Modern Methods of Sewage Disposal for Towns, Public Institutions, and Isolated Houses.* By Geo. E. Waring, jun., M. Inst. C.E. New York: D. van Nostrand Co. London: Sampson, Low, Marston, and Company. 1894.

*Encyclopédie des Travaux Publics, Architecture et Constructions Civiles, Charpenterie, Métallique Menuiserie en fer et Serrurerie.* Par J. Denfer. Tome premier. Paris: Gauthier, Villars, et Fils, Quai des Grands-Augustins, 55. 1894.

*An Introduction to the Differential and Integral Calculus.* For the use of students reading without the aid of a tutor. By Matthew Wyatt, F.R.G.S., F.I.I. London: Whittaker and Company. Rugby: George E. Over, the Rugby Press. 1894.

*Turning Lathes.* A manual for technical schools and apprentices. A guide to turning, screw-cutting, metal spinning, ornamental turning, &c., with 225 illustrations. Edited by James Lukin, B.A. Fourth edition. Colchester: Britannia Company. 1894.

*City and Guilds of London Institute for the Advancement of Technical Education. Programme of Technological Examinations, including Regulations for the Registration and Inspection of Classes in Technology and Manual Training, Session* 1894-95. London: Whittaker and Company.

*A Practical Treatise on Patents, Trade Marks, and Designs, with a Digest of Colonial and Foreign Patent Laws, the Text of the Patents, Designs, and Trade Marks' Acts,* 1883 *to* 1888 *(consolidated), &c. &c.* By David Fulton, A.M.I.C.E., Barrister-at-law. London: Jordan and Sons. 1894.

## RAILWAY MATTERS.

Five thousand of Mr. Adler's patent axle-box dust-shields have been ordered for use on the Rajputana-Malwa Railway.

The Tramways Committee of Glasgow have decided to erect half-mile stations on all the routes, to be distinguished after dark by a coloured lamp.

The Indian Railway administrations have been asked by Government to furnish all possible information for the projected International Railway Congress to be held in London in June, 1895.

A contract was recently obtained for locomotives for the Egyptian State Railroad, in which the tenders were made by weight, by the Société Franco-Belge. At the rate named the price of a 40-ton locomotive would be a little over £1600.

The survey of the proposed railway between Newcastle and Glasgow is expected to be commenced immediately by Messrs. Foreman and McCall, of Glasgow, who are also the engineers for the Glasgow Central and the Lanarkshire and Dumbartonshire Railways, presently under construction.

Among the railway projects that will be shortly decided by the Indian Government are the Chittagong-Akyab and Minhla Railway, about 420 miles in length; Delhi-Bhatinda-Bhawalpur Railway, about 400 miles in length; and the Rutlam-Muttra and Ujjain branch, about 460 miles in length.

At a meeting of the directors of the Highland Railway Company on Wednesday, it was resolved to make application in the ensuing Session of Parliament for powers to construct a line of railway from Inverness to Spean-bridge and Fort William. The new line, which will be fifty-eight miles in length, will cross the Caledonian Canal at Bona Ferry.

We read that the Bombay, Baroda and Central India Railway Company is desirous of effecting a direct junction between its metre gauge system and that at Cawnpore of the Oudh and Rohilkhund Railway Company. The Government of India do not wish to consider the question before the larger project for connecting the metre gauge lines in the North-West Provinces and Oudh is settled.

Messrs. R. Schram and Co. have recently executed two tunnelling plants to the order of the Assam-Bengal Railway Company, consisting of four air compressors, four boilers, and sixteen rock-boring machines, and accessories for driving the advance heading, &c. This plant is similar to that supplied by Messrs. Schram to the Indian Government in 1888, for constructing the Khojak Tunnel on the Chaman Extension Railway in Central Asia.

According to a recent report issued by the United States Department of Agriculture, the length of railway line in Mexico is 7297 miles. The report further states that about twenty miles of the railway across the Isthmus of Tehauntepec from Coatzacoalcos, on the Gulf, to Salina Cruz, on the Pacific, remain to be built at the centre of the isthmus. About 8 per cent. per annum will fairly represent the increase of railway movement in the territory.

A new railway from Ismailia to Port Said, a Decauville line, 2ft. 6½in. gauge, was opened in December last. The trains are well appointed, and shorten the journey to and from Ismailia by about an hour. The British Consul at Port Said observes:—"The line is only adapted for passenger traffic, but should it prove the precursor of a serious railway adapted for goods as well as passenger traffic, a considerable impetus to the trade of this place will be the result. As it is it will prove a convenience to passengers between this and other parts of Egypt."

The Expropriation Bill for constructing a railway between the station in the north part of Rotterdam and that at the eastern extremity has passed the Dutch Legislative Chambers. The necessity for such a line is proved by the extreme difficulty that large steamers have to reach the eastern—formerly the Rhenish—railway station, owing to their having to pass two bridges, whilst it is of the utmost importance that on the right bank of the river there should be harbours and quays in direct communication with the existing railway system. These works will entail a very large expenditure on the part of the town. Towards the completion of the connecting link by the Dutch Railway Company, the cost of which is estimated at £160,000, the State will contribute £100,000.

An accident occurred on the Midland Railway at Irchester Junction on Saturday night last. The driver of an express goods train from London made a mistake as to his signal, with the result that his engine struck the catch points, and his train, which consisted of 27 wagons, was thrown off the line and wrecked, many of the wagons being broken to atoms, and only the wheels left whole. The engine was much knocked about, and a signal-box standing at the junction was partially demolished by a truck being hurled against it, the signalman narrowly escaping serious injury. A passenger train narrowly escaped disaster, thanks to the presence of mind of the signalman, who jumped from the window of his box, and running down the line with his hand lamp managed to stop the incoming train within a few yards of the wreckage. Much damage was done to the rolling stock and permanent way. No one was seriously injured.

The floods in India are considerably interfering with railway traffic. The Rewari-Ferozepur Railway has been breached near Ferozepur Cantonments. The floods at Ruk have also spread, and passengers have now to tranship over a mile. In the course of transhipment the other day, two boats capsized and four men were drowned. Passengers to Chaman have to walk over the Khojak tunnel, about four miles, to get to the other side, making their own arrangements for the transport of their baggage. It appears that the floods on the Great Indian Peninsula Railway are almost beyond parallel in the history of the line. The *Indian Engineer* says that in one place the progress of a train was obstructed by a slip in the embankment, while its retreat was cut off by a mass of earth, estimated at several thousand tons, that had fallen over the line at a point which it had safely passed a few minutes earlier. The train appears to have been imprisoned for over sixty hours, and two other trains are reported to be blocked in a similar manner. Fortunately there has been no loss of life.

Major Marindin, in reporting to the Board of Trade the result of his inquiry into the recent collision at St. Pancras terminus, says that this collision, the serious consequences of which, as regards the leading vehicles in the train, and the passengers in them, were due, probably, to the effect of the great weight on the momentum of the train, rather than to the speed at which the train was running when it struck the buffer-stop, presents all the usual features of collisions of this class, except that there is more validity than usual in the excuse of the driver that the greasy state of the rails prevented the action of his brakes from taking proper effect in pulling up the train. As both brakes were in working order, he considers that the driver must therefore be held to have committed a technical breach of the rules in entering the station at a speed higher than a hand-brake speed, having miscalculated the speed at which he was running, but nevertheless, inasmuch as the rule quoted above may be fairly said to be never observed by any driver entering the station, and is allowed to be broken with impunity many times every day, this driver, who was only running at the usual speed, or very little more, and would probably have been able to stop his train by the use of his continuous brake, if it had not been for the greasy condition of the rails, cannot be considered to have been guilty of a serious offence.

## NOTES AND MEMORANDA.

The German output of pig iron for the six months ending June 30th was 2,649,071 tons, an increase of 247,131 tons on that of the first half of the year 1893.

The new cable recently laid by the Anglo-American Telegraph Company makes the eighth Atlantic cable connected with New York. It was laid in twelve days by the cable ship Scotia, and contains 600 lb. of copper to the nautical mile, being the largest conductor laid hitherto.

In London last week 2704 births and 1193 deaths were registered. Allowing for increase of population, the births were 86 above, and the deaths 272 below, the average numbers in the corresponding weeks of the last ten years. The annual death rate per 1000 from all causes, which was 15·4 in the preceding week, fell to 14·4.

At a recent meeting of the Paris Academy of Sciences a paper was read on "Electricity Considered as a Vortical Movement" by M. Ch. V. Zenger. The author showed that an electrical discharge produces a whirling movement in the gas through which it is discharged, which may be said to be a cyclone on a small scale, so completely are the phenomena of cyclones reproduced. The particles appear to describe a trajectory which may be represented by a screw of variable pitch traced on a conical surface.

At the annual meeting of the Federated Institution of Mining Engineers, held at Newcastle-on-Tyne on Wednesday, a paper was contributed by Mr. Edwin Gilpin, jun., on "Explosions in Nova Scotian Coal Mines," in which the writer expressed the opinion that although in no instance in Nova Scotia had coal dust caused an explosion, yet the presence of coal dust added to the area and destructiveness of the explosions. Mr. Joseph R. Wilson, of Philadelphia, contributed a paper describing the Shaw gas tester for indicating the presence and percentage of fire-damp and choke-damp in coal mines. It is a mechanical instrument, and although in the discussion exception was taken to its cumbersome character, its accuracy and usefulness were admitted. The next meeting will be held in Staffordshire in February.

The possibilities of natural gas evidently have not yet been exhausted, according to *Cassier's Magazine*. The latest use which would seem to have been found for it is the making of ice, the idea being to simply expand the gas from its usually high initial pressure down to or near that of the atmosphere, Nature having done all the preliminary work of compression and cooling, making the gas ready to absorb heat from its surroundings immediately upon being released from confinement. All that would be necessary, it is said, would be suitable coils or chambers into which the gas could be allowed to expand, but here it is evident that an important thermodynamic fact has been overlooked. It has been calculated that with an ordinary gas well, furnishing 1,500,000 cubic feet per day, something like fifty tons of ice could be turned out daily at an expense of about 50 cents a ton. The gas loses nothing but its pressure, retaining all its calorific value, and hence all its virtue, for rolling-mill and glassworks use, for heating brick, lime, and pottery kilns, and the endless number of other furnaces to which it is adapted. In a certain way, therefore, the gas may be regarded as affording something for nothing—a desideratum to which many in this world are constantly looking forward.

At a recent meeting of the Royal Society a paper was read "On the Viscosity of Water as Determined by Mr. J. B. Hannay, by Means of his Microrheometer," by Robert E. Barnett. In a paper entitled "On the Microrheometer," published in the *Phil. Trans.* for 1879, Mr. Hannay described an apparatus which he devised for measuring the rate of flow of liquids through a capillary tube, and gave the times of flow of water at various temperatures, and of certain aqueous salt-solutions which he had observed by its means. The capillary was 21 mm. long, and 0·0938 mm. in diameter; the bulb had a capacity of 4·053 c.c., and the pressure employed was that of 1 metre of water at 20 deg. In order to compare the results with those of other observers, the author has converted the measurements of time of flow recorded by Mr. Hannay for water into viscosity-coefficients by means of the formula:—

$$\eta = [(\pi r^4 p t) \div 8 V l] - V \rho \div 8 \pi l t.$$

The figures thus obtained are given in tabular form, and on comparison with the results given by Poiseuille, Slotte, Sprung, and Thorpe and Rodger, are seen to yield discordant values for the viscosity of water. Not only is the value at 0 deg. far below that of any known liquid, but it diminishes so rapidly that at 6 deg. and above it is a minus quantity. This paradoxical result is due to the fact that Mr. Hannay's experimental figures are inconsistent. It is physically impossible to pass such a volume of water under the stated pressure through a capillary tube of the dimensions given, in the times recorded. At 20 deg. for instance, the time of flow required under these conditions would be about 4600 seconds, instead of 131·3 seconds, as stated. The author has attempted in several ways to account for the discrepancy, but without success.

Professor Dewar, in his account of his researches in connection with phosphorescence, gives in explanation of its existence in many bodies, of which, however, phosphorus is not one, the following facts:—He found that photographic action does not cease at low temperatures, though it is diminished by 80 per cent. or more. While investigating this he noticed that the apparatus with which he was working was phosphorescing brightly, and he was thus induced to study phosphorescence itself at low temperatures. Beginning with gelatine and celluloid—substances which he was using in his photographic experiments—he found them to be very luminous when cooled to − 180 deg. and exposed for a second to the beam of a strong electric light. In the same way phosphorescence was produced in numerous other organic substances, such as ivory, bone, india-rubber, egg shell, feathers, cotton wool, linen, leather, blossoms of flowers, &c. Naturally the question presented itself of the relation of phosphorescence to structure. Professor Dewar therefore experimented with various definite organic compounds and found that one of the most beautiful phosphorescing bodies was the complex salt, the platino-cyanide of ammonium, which shone with a splendid green light. White of egg was brighter than the yolk, while albumen frozen on the outside of a tube and exposed to a light coming through a quartz lens, so that there was no glass to obstruct the ultra-violet rays, phosphoresced with a bright and blue light. From these and other experiments Professor Dewar is led to the provisional generalisation that the more complex a body is in structure, the more likely it is to phosphoresce, perhaps because in some way its structure enables it to take up the light vibrations with the more facility. A very curious point is the enormous effect of the presence of an almost infinitesimal quantity of organic matter. Pure water is weakly phosphorescent, but if it is very slightly impure it becomes strongly so. A perfectly clean plate of metal does not phosphoresce, but the merest trace of grease—such as is left by a touch of the hand—will make it brightly luminous. The differences which may be caused in the physical behaviour of substances by the addition of other substances in infinitesimal quantities is attracting a good deal of attention at the present time. The capability of oxygen for phosphorescing is another curious fact. In the gaseous state it can be made to glow if exposed to an electric spark while rushing into a large vacuum tube. This property is shared by its compounds, but is not possessed by hydrogen or any other gas. Here, strange to say, the presence of a trace of organic matter destroys the effect. Professor Dewar stated that a drop or two of ether or of scent in the room would make the experiment impossible for hours. That the phosphorescence is due to some kind of molecular change in the oxygen is indicated by the fact that ozone, among other products, is formed during the process.

## MISCELLANEA.

The Hampstead Electric Light Supply will come into use on October 1st.

Mr. J. Evelyn Williams, M. Inst. C.E., has removed to 57, Charing Cross, S.W.

An Exhibition of all matters connected with Optics and Photography will be held at the Royal Aquarium, from September 11th to October 6th.

The Red Star Line, of Antwerp, has concluded a contract with the Charleroi United Collieries Company for 12,000 tons of coal briquettes for use on its vessels.

A stone monument in memory of the late Sir Joseph Whitworth has been presented to Lady Whitworth by the inhabitants of Darley, Matlock, at which place the eminent engineer resided.

The Thames Ironworks and Shipbuilding Company has just constructed two dry docks 475ft. by 65ft. by 25ft., and 335ft. by 46ft. by 20ft. respectively, for facilitating the repairing of large vessels.

Herr Dowe has been officially informed that the cuirasses submitted by him for test to the committee of the Prussian War-office were worthless, as on each occasion of firing the bullets traversed the shield.

The sale of the electrical engineering plant of Messrs. Latimer Clark, Muirhead, and Co., of Regency-street, Westminster, by Messrs. Fuller, Horsey and Co. commenced on Tuesday continuing throughout the week.

The *Marine Review*, in its double issue of June 30th, gives, with a most complete description of the steamship North-West, seven plate-supplements, showing that ship at different stages of her construction and views of her machinery and interior.

The Laing, Wharton, and Down Construction Syndicate have acquired for the United Kingdom the patent rights of the Thomson-Houston systems, and they will in future carry on business under the title of "The British Thomson-Houston, Limited."

The London and India Docks Joint Committee have acquired land in the vicinity of Smithfield for the erection of extensive freezing chambers. Messrs. J. and E. Hall, of Dartford, have contracted for the refrigerating machinery, which will be of their hydro-carbonic acid type.

The Rockingham Railway and Jarrahdale Timber Company desires it to be known that the wood laid recently by the Paris authorities, and described in several papers as Brazilian mahogany, is really West Australian hardwood. This wood, "Jarrahdale Jarrah," has now been laid in the Rue Lafayette, Rue de Rivoli, Carrousel Arcades, and Boulevard Sébastopol.

Messrs. Maudslay, Sons and Field, London, have secured the contract for the construction of the triple-expansion engines and boilers for the battleship Cæsar, to be built at Plymouth. The engines are to indicate 12,000 horse-power under forced draught, giving a speed of 17½ knots, and under natural draught 10,000 indicated horse-power, with a speed of 16½ knots.

Messrs. Witty and Wyatt, of Leadenhall-street, have sent us a specimen of a patent asbestos and metal jointing for pipes which, they say, commands a considerable sale. It consists of a metal disc to which are affixed circles of asbestos cord, so arranged that the disc on being screwed up in the joint becomes corrugated. They are made in all sizes, and seem worthy of trial.

The Peninsular and Oriental Company's new steamer Caledonia is now lying in the Royal Albert Docks, opposite the Central Station. The public will have an opportunity of inspecting the vessel on Friday and Saturday, the 7th and 8th inst., when tickets to view will be obtainable at the docks. The proceeds will be devoted to the Seamen's and Dock Hospitals. We hope next week to give a full-page illustration of this, the finest vessel in the Peninsular and Oriental fleet.

A general meeting of Birmingham brass manufacturers has been held to consider the new regulations issued under the Factories Act, in regard to unhealthy occupations. The regulations provide that during the process of mixing metals the men shall be furnished with respirators, that suitable beverages shall be provided, and that the workshops shall be whitewashed every six months. It is understood that the meeting decided to memorialise the Home-office against some of the regulations. A meeting of operative brassfounders was subsequently held in support of the regulations.

The water in the Gohna Lake reached the top of the dam in the early morning of August 25th, and commenced to overflow in a small stream during the afternoon. About 320ft. of water escaped, and the lake afterwards commenced to settle down. It was then about two and a-half miles long, and quarter of a mile wide, with 400ft. maximum depth, which means a reduction of 260ft. in width and 375ft. in depth. Further accounts state that the water escaped with a tremendous roar, at an average rate of twenty-two miles an hour, carrying all before it, and in some gorges the water rose to a height of 160ft. No lives have been lost.

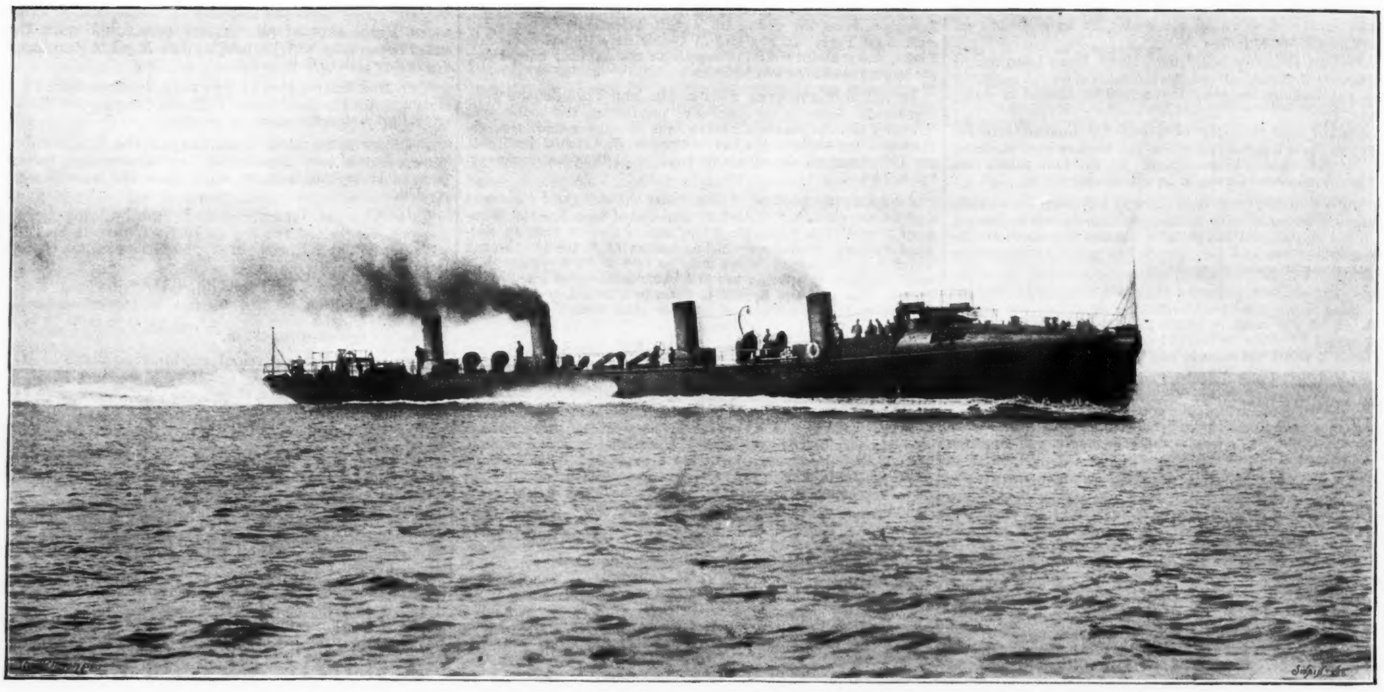
The Local Authority of Crewkerne, Somerset—the Chard Union—have at length determined to deal with the sewage difficulty in which the town has been for some years placed owing to the pollution of the river Parrett, and have instructed Mr. E. Bailey Denton, M.A., M. Inst. C.E.—Bailey Denton, Son, and North—of Palace-chambers, Westminster, to prepare plans for the purification of the sewage. The system to be adopted will be the screening by means of tanks placed at the mouth of the outfall sewer of the coarser matters contained in suspension, and the subsequent utilisation of the liquid upon land by means of intermittent filtration and wide irrigation.

The Italian Government being desirous of encouraging the preparation in Sicily of citric and tartaric acids, especially the former, has issued a decree offering prizes to persons who shall open factories for the preparation of these acids in Sicily. The first prize is to be one of £500, the second of £350, and the third of £175 sterling. To obtain the first prize both citric and tartaric acid must be made, the former in a quantity of at least ½ ton a day. Applications for the prizes must be made on Italian stamped paper not later than December 31st, 1895, and the works must be in operation not later than February, 1896, in which year the prizes will be distributed by the Minister of Agriculture. There are already two works in operation in the island.

An occurrence partaking of the nature of the Franklin experiment is reported from Aldershot. A captive balloon was held by a wire cable about 200ft. long. Suddenly it was struck by lightning, which ignited the gas, the balloon falling to earth amid a loud peal of thunder. Three of the sappers at the winch below were seen rolling on the ground, apparently in intense pain. This is attributed to their connection to the wire cable through the brass handles of the winch. One, a bugler, had the inside of his hand rather badly burnt, but the worst case of the three showed no external signs of injury. The car of the balloon fell without doing any damage. On examination it was found that all the upper part had been burnt away, though the metal valve was almost uninjured. Had anyone been in the car, even if he had escaped uninjured from the electric shock, he would have had a terrible fall. None of the sufferers were very seriously injured.

# H. M. S. LYNX AT FULL SPEED

MESSRS. LAIRD BROS., BIRKENHEAD, BUILDERS & ENGINEERS



## THE TORPEDO DESTROYERS, FERRET AND LYNX.

During the past month Messrs. Laird Brothers have had several successful trial trips of vessels on the Clyde. The necessity for going so far away arises from the fact that the measured mile at Liverpool is unsuited for these high-speed vessels. The trials of No. 97 First-class Torpedo Boat and the destroyer Ferret have already been reported on in our columns, and on Thursday week the Lynx destroyer, duplicate of the Ferret, completed her runs, and on Friday the Argentine Cruiser Patria.

The design of these destroyers, which Messrs. Laird submitted, was approved by the Admiralty in August, 1892, although for financial reasons the contract for construction was only placed in January, 1893, so that in comparison with other similar boats they have been promptly completed and tried. The engines differ from those of other Destroyers, but with slight modification are the same as those made by same builders for H.M.S. Rattlesnake in 1886, and the Argentine boats Espora and Rosales in 1890. The boilers, however, are of the Normand water-tube type.

The trial of the Lynx on Thursday week gave the following results:—Speed on measured mile, 27·15 knots; mean speed for three hours, 27·01 knots; the contract speed being 27 knots. The circle turning, starting, and stopping trials were subsequently gone through, each stage being entirely satisfactory. The instantaneous photograph which we reproduce, by Messrs. Adamson and Son, of Rothsay, represents the Ferret when she was going 27·61 knots.

The Admiralty were represented by Mr. Pledge and Mr. Ellis, also by Mr. Hobbs and Mr. Hocken, of Devonport Yard; the contractors by Mr. John Laird and Mr. Bevis.

## BRITISH ENTERPRISE IN PARAGUAY.

A recent report of the second secretary to the British Legation at Buenos Ayres, upon the Paraguay Central Railway, and its proposed extension to Encarnacion, is well worth the attention of intending investors in, and those who wish to form some idea of Paraguay.

Although the country offers many advantages as a field for colonisation, and the present Government is most anxious to attract immigration, there is a great drawback in the geographical situation of Paraguay, which renders it dependent on its neighbours for markets for its produce. The scarcity and uncertainty of these markets is a great obstacle to any rapid progress, and unless the Argentine and Umguyan markets are assured by treaty or otherwise, or new routes are opened to Brazil and the Atlantic, no sudden return of prosperity can be looked for.

There is plenty of room for legitimate enterprise in South America, and if the investing public would look more to the intrinsic paying powers of enterprises to which they are asked to subscribe, and less to the possible prices at which their shares may be quoted on the Stock Exchange, they would think less bitterly of South America. The causes of failure in railways, the principle enterprise in South America, are usually the large price paid for concessions; the culpable carelessness with which concessions are taken up in London for the sake of the commission they bring in, without sufficient trouble being taken to ensure accurate information about the country to be traversed; the carelessness with which concessions are drawn up, and the consequent legal difficulties which eat up profits; the line of country chosen, often with some object quite different from the ultimate success of the enterprise, or the development of the country; the scamped work of contractors, which in some cases has necessitated much expenditure on maintenance and renewal of the line.

The principal British enterprise in Paraguay is the Paraguay Central Railway, from Asuncion to Villa Encarnacion, on the river Paraná, a distance of 244 miles, of which the part from Asuncion to Pirapó, 154 miles long, has been completed, and works in three sections, Asuncion to Paraguari, 45 miles; Paraguari to Villa Rica, 47 miles; Villa Rica to Pirapó, 62 miles.

The capital of the company is £1,396,930, divided into 5 per cent. perpetual debenture stock £914,000, and share capital £482,930, the latter comprising 21,000 preference shares of £10 at 6 per cent., issued as fully paid to the Government, as part payment for portions of the line from Asuncion to Villa Rica, and 27,293 ordinary shares of £10.

According to the concession, the undertaking is entitled to a guarantee of interest from the Government of Paraguay for twenty years, at 6 per cent. per annum, upon £420,000, as to the railway from Asuncion to Villa Rica, and upon £3728 8s. per mile upon the line from the latter place to Encarnacion, being a total of £104,040 per annum. The Government complied with its obligations up to 1890, since when the guarantee has fallen into arrear. In September last an arrangement between the Government and the company for the payment of the guarantee was thrown out by the Senate, but the obligation was fully recognised, and proposals made for increased taxation on the export of Yerba to raise the required sum.

The gross receipts for the year ending 30th April, 1893, were £121,848, and the working expenses £115,888, as against £86,593, and £86,084 respectively in the previous year. The net profit rose from £509 to £5960. The proportion of working expenses to receipts fell from 99·53 to 95·74 per cent. The improvement would have been greater yet had it not been necessary to expend so much money on maintenance of permanent way, and renewal of bridges and sleepers. During the past year several stations were repaired on the Villa Rica-Paripó section—that last open to traffic—and the maintenance of which has lately been taken over by the company from the contractors. Twenty-seven bridges were renewed to original dimensions, three were renewed to increased dimensions, and four others repaired. On the Villa Rica-Pirapó section, most of the sleepers require renewal; the old ones, which have been only laid two years, are completely rotten, being made of soft wood, and a kick knocks a hole in them. "That this should be the case in a country where the hardest woods, and the best suited for railway sleepers are growing almost on the edge of the embankments is a scandal, and reflects discredit both on the constructors of the line and the engineer who passed the work. It is such scamped work which brings British contractors into discredit, and there are some almost incredible specimens of it in Missiones and Paraguay. In the old Jesuit town of Santa Maria, Missiones, the lintels of the doors are made of these hard woods, and although exposed to wind and weather for considerably over a century are perfectly sound. The work done by Guayrá Indians for the Jesuits contrasts most favourably with that done by British contractors for British companies." Much of the expenditure lately incurred has been rendered necessary by the bad management and misfortunes of former years. The improvement which has begun ought to continue, but the energies of those in charge should be entirely devoted to developing the traffic, with an intelligent knowledge of the country. The timber trade may be greatly increased, and agriculture much improved and extended. If the various colonies springing up along the line are carefully encouraged, they will soon have a considerable effect upon the traffic returns. Although the company is bound to extend the line to Villa Encarnacion, it is doubtful whether this would be advisable. Although the country between Pirapó and San Antonio, a distance of twenty-five miles, is very fertile, and contains considerable scattered population, the rivers Pirapó, Tébicuari-Guazú, and Tacúari, would require much expenditure on bridges. There are also two large streams near Encarnacion, and several large tracts of swampy land—flooded after rain—to be traversed, over which it would be very difficult to carry a line. Encarnacion is a small town on the Paraná, and the principal port of Paraguay, on the eastern side. It is far from flourishing, and there are numbers of deserted houses, the Argentine duties on tobacco, and the stringent measures against smuggling having paralysed trade in the Eastern part of Paraguay. In view of these facts an extension to Encarnacion could not possibly pay, unless in connection with an extensive scheme of colonisation.

One object of the extension is to place the Paraguayan railway in connection with the proposed line from Posadas—on the Argentine bank of the Paraná—to Monte Caseros. This line was begun in 1889, and several sections were constructed, but the bursting of the boom in the River Plate, and the failure of the contractors, brought the enterprise to an abrupt termination. There is some talk of proceeding with the construction of the Argentine North-Eastern Railway, but it is doubtful whether at present it would be a success. Frequent revolutions in the neighbouring province of Corrientes, and desultory fighting on the Brazilian bank of the Uruguay having so unsettled the country that even the industrious cannot live. In addition to this, the route might have to compete with two others which are in a more advanced state of construction, viz., Resistencia—Santa Fé—Rosario, Corrientes—Mercedes—Concordia, but these routes would not open up any new market. A proposal is said to have been made by Mr. C. R. Thursby to the Paraguay Central Railway Company, to study another route, viz., Villa Rica to a point on the Paraná, north of the Rio Mondáy, and opposite the mouth of the Rio Iguazú de Curitiba, and that the line should be continued to Paranaguá or some Brazilian port on the Atlantic. This route, by following the water shed to the north of the Tebicuari, would avoid the heavy expenditure on bridges entailed by the construction of the other line. Such a line would have the immense advantage of opening the Brazilian market to Paraguayan produce, and bringing Rio Janeiro within nearly the same distance from Asuncion as Buenos Ayres. Little is accurately known of the country in question, but it is said to have a considerable population, both on the Paraguayan and Brazilian side.

A scheme has been proposed by La Compagniè Francaise des Chemins de Fer Brésiliens to construct a railway from Paranaguá on the Atlantic to the mouth of the Ignazú de Curitiba, and that part of the line from Paranaguá to the town of Curitiba has been constructed. In addition to these routes there is the river route, *viâ* the rivers Paraguay and Paraná, which, if properly taken advantage of, would compete with the railways, both in passengers and goods traffic, with every chance of success.

Nothing has been done on the Paraguayan section of the proposed line from Asuncion to Villa Igà timi with a branch to Tacúrupúcú on the Upper Paranà, and which was to form part of a trans-continental railway to the Atlantic.

This report, No. 1357, Annual Series, contains details of the trade routes and a map of the proposed railways.

An interesting feature of the report is the description of a visit to the "New Australian Co-operative Settlement Association" in the department of Caagúazu, near Villa Rica, for the purpose of inquiring into the causes of the expulsion of three members, and the secession of about one-third of the colony. The community was founded on co-operative principles, with the object of "putting into practice upon a voluntary basis, and under the most favourable conditions available, that form of industrial association which will secure justice for all." The dispute began in personal differences, aggravated by the intrigues of two or three men. An agreement had been signed binding the colonists to total abstinence until preliminary difficulties had been overcome—a space of three years. The agreement was broken by the three men expelled. The ladies joined in the quarrel, strong language was used, threats exchanged, and eighty-five men, women, and children left the colony, sacrificing their stake in the Association, which amounts to a minimum of £60.

A few more such secessions will ruin the movement, disgust the Paraguayan Government, and give the British colonists a bad name in South America.[*] Under good management and on reasonable lines, the colony should be a success, but it is probable that the chairman's views are too straight and his administration too strict for ordinary men.

The colonists started with everything in their favour—free land, immunity from taxation, a good climate, and the command of a certain amount of capital. They are a fine class of men, and if they were less disposed to stand on the letter of their rights, and took a more reasonable view of the feelings of their fellows, they would be sure to succeed. As it is, they came to found Utopia, and in a few weeks created—as they said—"a hell upon earth."

---

[*] Later information states the colony to be rapidly disintegrating.

# ANTWERP EXHIBITION—HYDRAULIC TURNTABLE

M. G. FRANCOIS, BOUFFIOULX ENGINEER

Fig I.

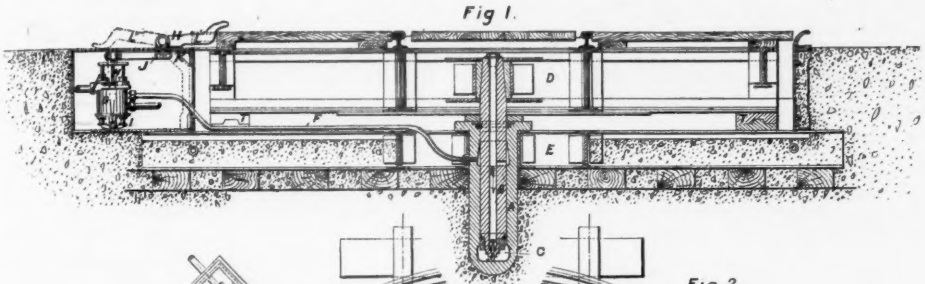


Fig 2.

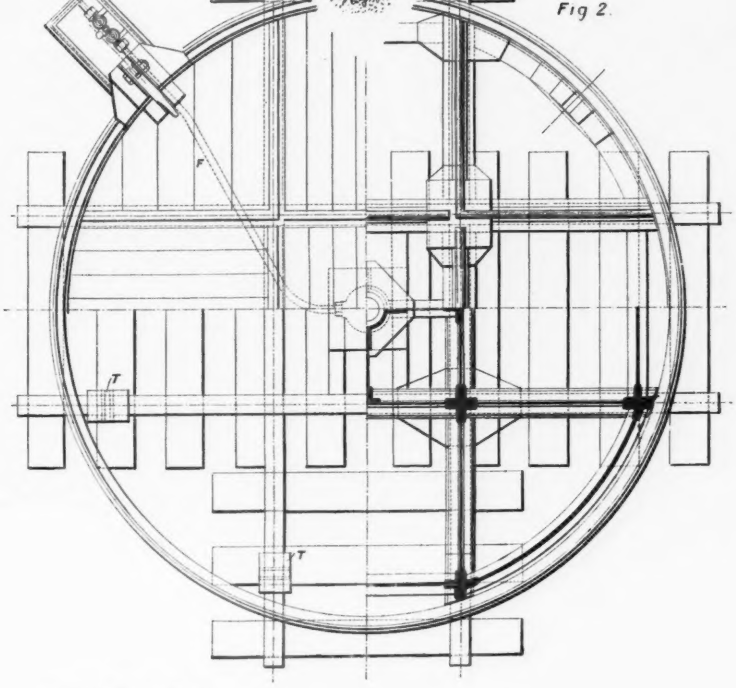

Fig 3.

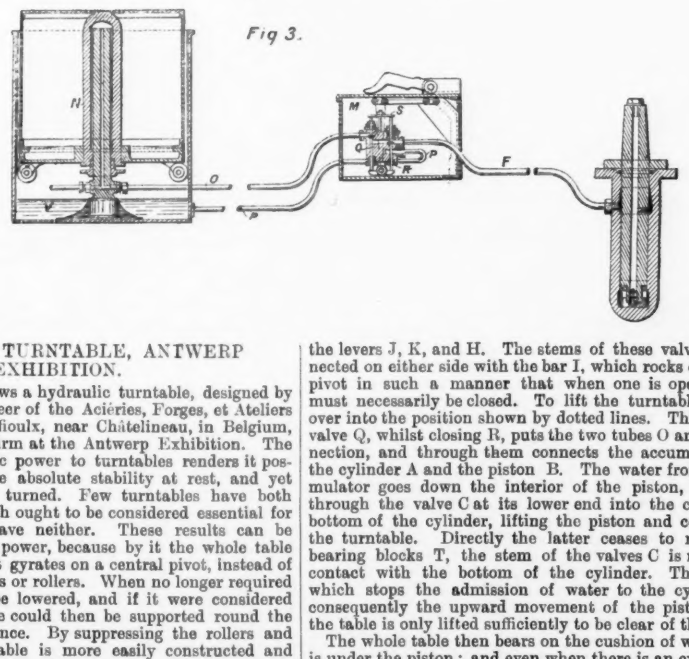

## HYDRAULIC TURNTABLE, ANTWERP EXHIBITION.

Our illustration shows a hydraulic turntable, designed by M. G. François, engineer of the Aciéries, Forges, et Ateliers de la Biesme, of Bouffioulx, near Châtelineau, in Belgium, and exhibited by that firm at the Antwerp Exhibition. The application of hydraulic power to turntables renders it possible for them to have absolute stability at rest, and yet for them to be easily turned. Few turntables have both of these qualities, which ought to be considered essential for them, whilst many have neither. These results can be obtained by hydraulic power, because by it the whole table can be lifted, so that it gyrates on a central pivot, instead of having to run on wheels or rollers. When no longer required to turn, the pivot can be lowered, and if it were considered necessary, the turntable could then be supported round the whole of its circumference. By suppressing the rollers and roller path, the turntable is more easily constructed and erected, and less likely to get out of order, and there are several minor advantages—for instance, less lubrication is required, and the pit is less likely to fill with water during heavy rains.

Fig. 1 is a cross section of the turntable; Fig. 2 is a plan, with the flooring partly removed, and Fig. 3 is a section showing the connection of the hydraulic valves with the accumulator on one hand, and with the cylinder under the centre of the turntable on the other. This hydraulic cylinder, marked A in Fig. 1, is suspended from a steel frame E, carried by wooden sleepers which rest on the ground. This frame is preferably made in the form of a cross; and it supports at its ends the bearing blocks T, on which the turntable D usually rests. The hollow piston B, which is turned conically at its upper end, is firmly secured to the table D, whilst its lower end is inserted into the cylinder A. At the foot of the piston is a small valve C, whose stem rests on the bottom of the cylinder. The valve is thus kept open as long as the turntable is at rest. A tube F connects the space inside the piston, and the cavity at the bottom of the cylinder, with the valves Q and R, which are also placed in communication with the accumulator N, by means of the tube O. The construction of the accumulator will be clearly seen from the drawing.

When the turntable is at rest, the handle L fits into a groove in its rim, and serves to lock it in position. It also serves to open and shut the valves Q and R, by means of the levers J, K, and H. The stems of these valves are connected on either side with the bar I, which rocks on a central pivot in such a manner that when one is open the other must necessarily be closed. To lift the turntable, L is put over into the position shown by dotted lines. This opens the valve Q, whilst closing R, puts the two tubes O and F in connection, and through them connects the accumulator with the cylinder A and the piston B. The water from the accumulator goes down the interior of the piston, and passes through the valve C at its lower end into the cavity at the bottom of the cylinder, lifting the piston and consequently the turntable. Directly the latter ceases to rest on the bearing blocks T, the stem of the valves C is no longer in contact with the bottom of the cylinder. This closes C, which stops the admission of water to the cylinder, and consequently the upward movement of the piston, so that the table is only lifted sufficiently to be clear of the blocks T.

The whole table then bears on the cushion of water which is under the piston; and even when there is an exceptionally heavy wagon on it, a man can easily turn it with one hand. As soon as the table has been turned to the desired position, the handle L is put back. This opens the valve R, which allows the water to escape from the cavity at the bottom of the cylinder, and to flow through the pipe P into the receptacle V. The removal of the water allows the table to descend, and again to bear on the supports T. As the quantity of water used is very trifling, the raising and lowering of the table is almost instantaneous. In the Exhibition a hand pump is attached to the accumulator; and as the liquid is used over and over again, a mixture of water and glycerine, or any other fluid, may be substituted for water, if considered preferable.

---

**Death of Mr. Charles Wood.**—It is with much regret that we have to record the death of Mr. Charles Wood, late chief of the mechanical engineering department at the Silvertown Works. He was only 55 years at the time of his death on the 30th ult., but had done 23 years useful work for the Silvertown Company. Previous to this he had worked for the Basin Foundry Company at Glasgow, where he had been originally apprenticed. Whilst at Silvertown Mr. Wood was largely responsible for the construction of the Company's cable machinery and electric lighting machines up to the time of his much-regretted death; he will be difficult to replace. Charles Wood was admired and respected by all who knew him. He well earned the reputation of an industrious, painstaking, and very able engineer.

# METHODS OF DETERMINING THE DRYNESS OF STEAM.*

By W. C. Unwin, F.R.S., M. Inst. C.E.

(*Concluded from page* 200)

### Tests to Determine the Relative Trustworthiness of Different Methods.

*Test of the wire-drawing calorimeter.*—The instrument tried was one received direct from Mr. Barrus. It seemed extremely desirable to get some kind of absolute test of the trustworthiness of this instrument, as it is much the simplest to use for nearly dry steam. Especially it seemed desirable to ascertain whether any correction for radiation or other loss of heat would be necessary. This can only be tested by using steam of known condition. The direction given in the instructions accompanying the instrument is to test it with the steam from a boiler not doing much work, the steam being then *assumed* to be dry saturated steam. But this is inconclusive. To test this instrument a small superheater was constructed, heated by a row of gas jets. Then there is definitely superheated steam in both chambers of the instrument. Let $t_1'$ be the temperature in the first chamber, $t_2'$ the temperature in the second chamber after wire-drawing. Apart from any loss by radiation, and assuming that the kinetic energy due to passage through the orifice is reconverted by friction into heat, the difference of temperature in the two chambers can be calculated. Let $p_1$ be the pressure in the first chamber, and $t_1$ the corresponding temperature of saturated steam; $p_2$ the pressure in the second chamber, and $t_2$ the corresponding temperature. Since the total heat per pound is the same in both chambers,

$$1082 + 0{\cdot}305\, t_1 + 0{\cdot}48\, (t_1' - t_1) = 1082 + 0{\cdot}305\, t_2 + 0{\cdot}48$$
$$(t_2' - t_2)\quad t_1' - t_2' = 0{\cdot}3646\, (t_1 - t_2).$$

In the following experiment the pressure in the second chamber was slightly greater than atmospheric pressure, and the corresponding temperature was 215 deg. Putting in this value—

$$t_1' - t_2' = 0{\cdot}3646\, t_1 - 78{\cdot}4.$$

*Test of the Barrus wire-drawing calorimeter at the Central Technical College with superheated steam.*—The steam was taken from a Babcock-Wilcox boiler, and the engine was running. Steam valve opened at 2 h. 49 min., and gas jets of superheater lighted at 3 h. 1 min. Barometer 30·02 = 14·75 lb. per square inch. Pressures taken by a Schaffer and Budenberg gauge.

| Time. | Pressure by gauge—lbs. per sq. in. | Absolute pressure—lbs. per sq. in. | Saturation temperature due to pressure in 1st chamber | Observed temperature in first chamber. | Observed temp'rature in second chamber. | Observed $t_1' - t_2'$ | Calculated $t_1' - t_2'$ |
|---|---|---|---|---|---|---|---|
| h. m. | | | $t_1$ | $t_1'$ | $t_2'$ | | |
| 3 32½ | 54 | 68·75 | 301·5 | 324 | 292 | 32 | 31·6 |

| 3 47½ | 54 | 68·75 | 301·5 | 324 | 295 | 29 | 31·6 |
| 3 50 | 54·5 | 69·25 | 302·0 | 325·5 | 296 | 29·5 | 31·7 |
| 3 52½ | 54 | 68·75 | 301·5 | 325·5 | 296·5 | 29 | 31·6 |
| 3 55 | 53·5 | 68·25 | 301·0 | 326 | 297 | 29 | 31·4 |
| 3 57½ | 54 | 68·75 | 301·5 | 327 | 298 | 29 | 31·6 |
| 4 0 | 56 | 70·75 | 303·4 | 323 | 291 | 32 | 32·2 |
| 4 2½ | 56·5 | 71·25 | 303·9 | 322 | 288 | 34 | 32·4 |
| 4 5 | 54·5 | 69·25 | 302·0 | 325 | 291 | 34 | 31·7 |
| 4 7½ | 54·5 | 69·25 | 302·0 | 329·5 | 298 | 31·5 | 31·7 |
| 4 10 | 54 | 68·75 | 301·5 | 332 | 302 | 30 | 31·6 |
| 4 12½ | 54 | 68·75 | 301·5 | 334 | 304·5 | 29·5 | 31·6 |
| Means .. | — | — | 301·9 | 325·9 | 295·1 | 30·78 | 31·45 |

The mean superheat in the first chamber was 24 deg., that in the second chamber 80·1 deg. There could be no doubt, therefore, as to the quality of the steam. The observed difference of temperature $t_1' - t_2'$ was remarkably constant, and the differences from the calculated values are not great. The mean difference of the observed and calculated values of $t_1' - t_2'$ is only 0·67. Necessarily the common pressure gauge readings are only approximate, and the difference is less than that which may be due to unavoidable inaccuracy in reading the pressure gauge. Since in ordinary use about 20 deg. fall of the temperature $t_2'$ corresponds to 1 per cent. of moisture in the steam, it appears that the calculated value of $t_2'$ for dry steam is practically exact. Other experiments—though not over any great range of pressures—have been made. So far as they have gone, they confirm this result. Hence it appears that no correction of the theoretical calculation is necessary to obtain practical accuracy, and that the assumption that all the kinetic energy at the orifice reappears as heat is practically true. In Fig. 6 the temperature curves for the experiment above have been plotted. The saturation temperature $t_1$, due to the steam pressure, calculated from the pressure gauge readings, and the actual temperature of the superheated steam $t_{s1}$, are shown by the two upper lines. The temperature of the superheated steam in the second chamber $t_{s2}$ is shown by a full line, and the calculated value of $t_{s2}$ by a dotted line. The thermometer being in an iron tube necessarily lags a little behind the temperature in the chamber.

*Test of a combined separating and wire-drawing calorimeter by Mr. Barrus.*—A very careful test is given by Mr. Barrus in his paper,[18] in which the steam passing through the instrument was condensed in a surface condenser and measured. Pairs of trials were made under identical conditions; in one the separator was in use, and in the other the separator was shut off. Each trial lasted usually an hour, sometimes two hours.

*Pairs of Trials in one of which most of the Moisture was Trapped in the Separator, and in the other the whole Measured by Wire-drawing or Heat Gauge.*

| No. | Temperature by upper thermometer. | Temperature by lower thermometer. | Weight of steam condensed in surface condenser per hour. | Weight of water from separator per hour. | Total weight of steam used per hour. | Moisture calculated from separator, per cent. | Moisture calculated from heat gauge, per cent. | Dryness of steam. | Total moisture, per cent. |
|---|---|---|---|---|---|---|---|---|---|
| | $t_1$ | $t_2$ | lbs. | lbs. | lbs. | | | $x$ | |
| 1 | 312·4<br>312·2 | 265·4<br>239·6 | 53·87<br>53·89 | 0·644 | 54·51<br>53·89 | 1·18 | 0·40<br>1·80 | ·984<br>·982 | 1·58<br>1·80 |
| 2 | 312·5<br>313·8 | 267·0<br>241·4 | 53·58<br>54·97 | 0·684 | 54·26<br>54·97 | 1·26 | 0·30<br>1·70 | ·984<br>·983 | 1·56<br>1·70 |
| 3 | 313·6<br>313·1 | 266·4<br>225·0 | 53·91<br>54·40 | 1·284 | 55·19<br>54·40 | 2·33 | 0·40<br>2·60 | ·973<br>·974 | 2·73<br>2·60 |
| 4 | 314·1<br>314·1 | 267·2<br>223·9 | 54·50<br>55·32 | 1·350 | 55·85<br>55·32 | 2·42 | 0·40<br>2·80 | ·972<br>·972 | 2·82<br>2·80 |
| 5 | 314·3<br>314·3 | 267·9<br>227·1 | 55·00<br>55·82 | 1·309 | 56·31<br>55·82 | 2·33 | 0·40<br>2·60 | ·973<br>·974 | 2·73<br>2·60 |

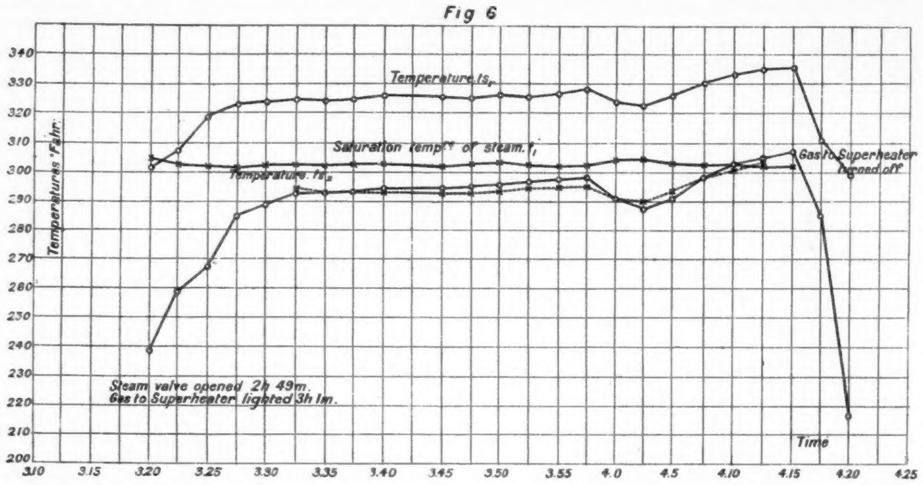
Mr. Barrus has used these results in an attempt to calculate a value for the specific heat of superheated steam, and gets values ranging from 0·415 to 0 519, the mean value being 0·475, almost exactly the value generally assumed. It is hardly to be expected that experiments of this kind are accurate enough to prove that the specific heat varies. On the other hand, Mr. Barrus has neglected to calculate the dryness fraction of the steam, and so has missed the striking evidence these results afford to the general accuracy of the instrument. The separator was not a very perfect one, and allowed about 0·4 per cent. of moisture to pass. But the separator results cannot be much wrong, for they are measured results depending on no assumed constants. The error in calculating the 0·4 per cent. passing the separator cannot be large enough to much affect the total result. On the other hand, the calculation from the heat gauge when the separator was cut out, which depends on the assumed value 0 48 of the specific heat and on the theory of the instrument, agrees strikingly with the separator results.

---

* Report of the Committee, consisting of Sir F. J. Bramwell, Bart. (chairman), Professor T. H. Beare, Mr. Jeremiah Head, Professor A. B. W. Kennedy, Professor Osborne Reynolds, Mr. Mair Rumley, Mr. C. I. Wilson, and Professor W. C. Unwin (secretary).

[18] Amer. Soc. Mechan. Engineers, 1890.

Fig 6



*Test of wire-drawing and separating calorimeter combined.*—The following tests have been arranged to determine how far it is true, as stated by Carpenter, that a separator traps the whole of the moisture, even with very moist steam. The Barrus calorimeter was used with its drip box or separator. The amount of water deposited in the drip box was measured. Observations also were taken of the temperatures in the two chambers of the wire-drawing part of the instrument. Let $t_1$ $t_2$ be the temperatures in the first and second chambers of the wire-drawing part, $t_3$ the saturation temperature of steam in the second chamber calculated from the pressure. Then, from the formula given above,

$$x = \frac{1116 - t_1 - 0{\cdot}19t_3 + 0{\cdot}48t_2}{1116 - 0{\cdot}71t_1}.$$

The dryness in each experiment has been calculated by this formula for the steam passing from the drip box into the wire-drawing part.

*Tests of Barrus Calorimeter with Separator attached at the Central Technical College.*

| Date. | Time. | $t_1$ | $t_2$ | $t_3$ | $x$ | Per cent. of moisture trapped in separator. |
|---|---|---|---|---|---|---|
| | H. M. S. | | | | | |
| Nov. 27, 1893.. | 4 23 30<br>4 27 45 | 294·5 | 256·2 | 215 | ·996 | 9 |
| | 4 27 45<br>4 32 15 | 292·5 | 257·0 | 215 | ·998 | 9 |
| | 4 32 15<br>4 37 15 | 289·0 | 257·0 | 215 | ·998 | 9 |
| Mar. 15, 1894.. | 11 9 0<br>11 37 30 | 290·5 | 254·9 | 215 | ·997 | 5 |
| | 11 51 0<br>12 21 0 | 286·4 | 251·5 | 215 | ·996 | 5·7 |
| Mar. 28 .. .. | 1 2 40<br>1 11 52 | 298·0 | 262·0 | 215 | ·997 | 4·4 |
| Mean .. | — | — | — | — | ·997 | — |

It will be seen that, although the steam entered the separator with more than 4·4 per cent. to 9 per cent. of moisture, the steam passing through the wire-drawing part has only from 0·4 per cent. to 0·2 per cent. of moisture. The mean dryness fraction of the steam passing to the second chamber in the six tests was 0·997, so that the error of using the separator without the wire-drawing part would generally, for practical purposes, lead to an error of no great importance, at any rate, when the steam had initially more than 1 per cent. of moisture. Further, the separator on the Barrus calorimeter is not quite so well arranged as that of the Carpenter calorimeter. The steam leaving the latter is no doubt drier than that leaving the separator of the Barrus calorimeter.

*Test of a Carpenter separating calorimeter showing the influence of radiation from the steam pipe in producing moisture in steam.*—The Barrus calorimeter and Carpenter calorimeter were fixed side by by side for comparative tests. A branch pipe 30ft. long brought the steam from the main steam pipe, which delivered steam to the engine. This pipe was well clothed with Keenan's composition. The engine was running, so that there was a considerable flow of steam along the main steam pipe. Two pairs of tests were made. In one the Carpenter calorimeter alone was used, and the flow of steam along the 30ft. branch pipe was comparatively slow. In the other pair, steam was flowing through the Barrus calorimeter also. As this uses twice as much steam as the Carpenter, the rate of flow was about three times greater than in the first pair of tests.

*Test with Carpenter separating Calorimeter at the Central Technical College, March 28th, 1894.*

The only difference in these two sets of experiments was that the rate of flow along the branch steam pipe was different. In the first set the mean moisture was 13·82 per cent., in the second set 3·93 per cent., being greater when the steam current was slower. The difference is due to condensation in the steam pipe. The result is important as showing how large the proportionate condensation may be, even in a well-clothed steam pipe, when the rate of flow is small, and also how important it is, in using calorimeters of this kind which take only a small quantity of steam, to place them closely adjacent to the engine or boiler tested.

*Simultaneous wire-drawing and salt test on a Babcock boiler at the Central Technical College.*—Steam was taken by a short pipe clothed with felt from the casting carrying the safety valve at the top of the boiler. This pipe branched to the Barrus calorimeter and to a worm in a cold water tank, closely adjacent to each other. The following table gives the Barrus calorimeter results in full to show the consistency of the determinations :—

*Test with a Barrus Wire-drawing Calorimeter, June 5th,* 1894.

Steam valve opened at 11h. 25m. a.m. Barometer, 29·88in. = 14·68 lb. per sq. inch. Pressure in second chamber, about 4in of water, or ·14 lb. per sq. inch. Temperature of saturated steam corresponding to pressure in second chamber taken at $t_3$ = 213 deg.

| Time. | Pressure by gauge on boiler, lb. per sq. in | Temperature of steam, $t_1$. | Temperature after wire-drawing, $t_2$. | Dryness fraction of steam, $x$. | Per cent. of moisture in steam. |

While these calorimeter tests were made, three samples of boiler water were taken from the gauge cock and three samples of steam condensed in the copper worm. These were carefully analysed by Mr. Crighton, under the direction of Professor Armstrong, F.R.S. The following are the results :—

| Boiler water. | | Condensed steam. | | Moisture in steam, per cent. |
|---|---|---|---|---|
| Time. | Grams of Na Cl in 100 c.c. | Time. | Grams of Na Cl in 100 c.c. | |

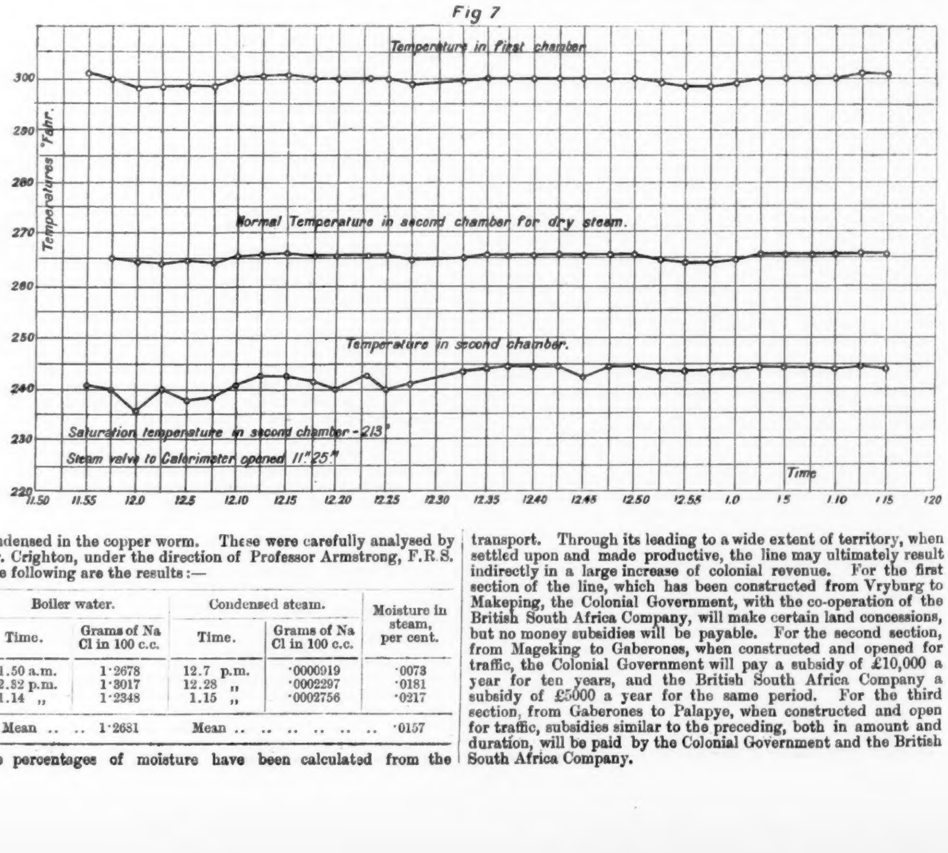
The percentages of moisture have been calculated from the mean saltness of the boiler water. It will be seen they vary considerably. Further, the moistness from the salt test is only one-hundredth as great as that shown by the wire-drawing calorimeter. The temperatures for the Barrus calorimeter are plotted in Fig. 7, in order to show how remarkably regular and consistent the observations with a wire-drawing calorimeter are.

Fig 7



*Simultaneous wire-drawing and salt test.*—In the following test the Barrus wire-drawing calorimeter was used, the observations being taken by Professor Unwin. Simultaneously Professor Kennedy took samples of the condensed steam and boiler water, and determined the moisture in the steam by the salt test.

*Test of water tube boiler, using wire-drawing calorimeter, April 11th,* 1894.—The temperatures of the calorimeter thermometers given are the means of two to five observations at intervals of about one minute, taken after steam had been flowing through calorimeter for about twenty minutes. They were taken as soon as the temperatures had become steady. Barometer 29 936in. = 14 70 lb. per square inch. Temperature of saturated steam corresponding to pressure in second chamber assumed 214 deg.

| — | Time. | Pressure by gauge on boiler, lb. per sq. in. | Temperature in first chamber, $t_1$ | Temperature in second chamber, $t_2$ | Dryness fraction of steam, $x$ | Moisture in steam per cent. |

It is obvious that the salt test shows much less moisture than the calorimeter, the mean moisture by the former being 1 per cent., and by the latter only about one-tenth as much. Naturally the salt test which shows only mechanical priming should give a lower result than the calorimeter. But the salt tests are so irregular that it is impossible not to doubt a little the accuracy of the method.

The moisture found by condensing some steam and determining the amount of salt during the same trials was as follows :—

| — | Sample. | Time. | Dryness fraction. | Moisture per cent. |

Vryburg to Palapye Railway, British Bechuanaland.—According to a Treasury Minute, the leading features of the agreement between the Government of British Bechuanaland, the British South Africa Company, and the Bechuanaland Railway Company, for the extension and working of the Vryburg-Mageking Railway—gauge 3ft. 6in.—to Palapye, are :—The revenues of British Bechuanaland will be changed with a subsidy to the railway company, amounting in time to £20,000 a year for a period of years, but by means of the new railway the Colonial Government expects to effect an at least equal saving in the cost of police and transport. Through its leading to a wide extent of territory, when settled upon and made productive, the line may ultimately result indirectly in a large increase of colonial revenue. For the first section of the line, which has been constructed from Vryburg to Makeping, the Colonial Government, with the co-operation of the British South Africa Company, will make certain land concessions, but no money subsidies will be payable. For the second section, from Mageking to Gaberones, when constructed and opened for traffic, the Colonial Government will pay a subsidy of £10,000 a year for ten years, and the British South Africa Company a subsidy of £5000 a year for the same period. For the third section, from Gaberones to Palapye, when constructed and open for traffic, subsidies similar to the preceding, both in amount and duration, will be paid by the Colonial Government and the British South Africa Company.

## AUSTRALIAN ENGINEERING NOTES.

(*From our own Correspondent.*)

THE annual report of the New Zealand railways for the year ending 31st March, 1894, has just been published. The result of the year's working shows an increase under all heads of revenue excepting the carriage of grain and merchandise, under which there was a reduction of 112,446 tons of grain and 20,295 of merchandise traffic, the total revenue being decreased by £8729 on last year's figures. The expenditure has increased £3217. Sixty-one miles of new lines were added during the year. The fruit industry is stated to be attaining considerable dimensions, 900 tons being carried to Dunedin and Auckland—no less than 326 tons of this was carried forty to fifty miles by road on horse wagons to the railway stations. The permanent way has been well looked after; 19,303 rails have been renewed, 82 per cent. being 53 lb. steel rails. About 155,502 sleepers were laid for ordinary renewals and about 22,000 laid to increase the number per rail length.

Rates have been reduced in almost all classes of goods, and passenger fares have been reduced in several instances. There is plenty of room for reductions in freights and fares, as the rates are considerably higher than what prevails in the other colonies. The following is a summary of the principal particulars:—

| | Year 1894. | Year 1893. |
|---|---|---|
| Miles open | 1,948 | 1,886 |
| Train mileage | 3,113,231 | 3,002,174 |
| Gross earnings | £1,172,793 | £1,181,522 |
| Gross earnings per mile of line | £618 | £631 |
| Gross earnings per train mile | 7s. 6½d. | 7s. 10½d. |
| Total working expenses | £735,359 | £732,142 |
| Total working expenses per mile of line | £384 | £391 |
| Total working expenses per train mile | 4s. 8¾d. | 4s. 10½d. |
| Net earnings | £437,434 | £449,380 |
| Net earnings per mile of line | £229 | £240 |
| Net earnings per train mile | 2s. 9¾d. | 3s. |
| Working expenses to gross earnings, per cent. | 62·70 | 61·97 |

The report of the Tasmanian Government railways is always very late in appearing, but this year it is earlier than usual. The report is for the year ending 31st December, 1893, and the following summary gives the position of these railways at that date:—

| | |
|---|---|
| Capital cost of lines open | £3,510,196 |
| Total miles open for traffic | 419·75 |
| Gross revenue | £152,083 |
| Working expenditure | £136,468 |
| Net earnings | £15,615 |
| Working expenses to revenue, per cent. | 89·73 |
| Train mileage | 799,823 |

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*Fire hydrant.*—In the new Eddy hydrant the vertical stem or rod carrying the valve extends through the valve, and has a threaded end entering a bushed nut carried in the bottom of the casing. By this arrangement the valve is held in place from the bottom, and cannot lift in case the upper part of the casting or rod is broken. The valve is made with a cylindrical piece of smaller section on the lower side, and as this enters the seat it gradually reduces the flow of water before the valve comes upon the seat, thus avoiding any "water hammer." A collar on the stem prevents the rod being screwed out of the bottom bushing. A drip plug at the valve seat is automatically opened when the valve is shut, thus allowing the water in the casing above the valve to escape, while the plug is closed when the valve is opened. The valve is rubber faced, but does not revolve on its seat, as the stem revolves in the centre of the valve.

*Narrow gauge railways.*—The narrow gauge craze which obtained in the United States some years ago has long since died out, and enormous sums of money have been spent in widening the gauge of hundred of miles of track to allow of through traffic and connections. Some few roads of respectable length still retain the 3ft. or 3½ft. gauge, but their change is only a question of time and financial conditions. The East and West Texas Railway is about to change 230 miles of 3ft. to the standard gauge, as it has standard gauge roads at each end of its line. A similar fate has attended the old southern gauge of 5ft., and the Erie Railroad gauge of 6ft., some thousands of miles of track being removed to the standard gauge, on account of the difficulty and expense of through carriage of freight. A fifty mile branch of the Nashville and Chattanooga Railway is also to be changed. There are certain conditions under which a narrow gauge is admissible, as for short isolated lines, and some of the curious little 24in. railways have been very satisfactory, but some of these little branches have been absorbed and changed by standard gauge roads. With proper care in locating and laying out a railway for ordinary traffic, there are few cases where a standard gauge road cannot be as well and as cheaply built as a road of anything over 3ft. gauge. There are two 3ft. roads in Iowa, which are said to carry the same loads and at the same speeds as the standard gauge, trains running steadily and easily at fifty miles per hour, but it is probable that no increase in cost need have been required for the wider gauge, while the expense of widening must be incurred sooner or later.

*Gas engines for electric plant.*—The electric light plant at Danbury is driven by three Otto gas engines of 100 horse power each. Each engine has two horizontal cylinders 14½in. by 24in., placed one above the other, with both connecting rods driving the same crank pin, the main shaft being midway between the centre lines of the cylinders. The belt fly-wheels are 6ft. in diameter, and run at 165 revolutions per minute. The engines are placed side by side, with the crank shafts in line and connected by flexible couplings, so that one, two, or three engines can be run at a time. A small 15-horse power Westinghouse steam engine is used to start the gas engines by driving the driven shaft, and thus revolving the fly-wheels. The engines are coupled up with the cranks 180 or 120 deg. apart, according whether two or three engines are in operation. The governors are also connected up so that the plant acts as one engine with four or six cylinders. The cylinders are water jacketed, the water of circulation being taken from the gas-holder. The boiler for the starting engine is used also in making the producer gas and for heating the power station. The exhaust pipes have enlarged pockets to deaden the noise, and these pipes lead to a small brick chimney. The plant has been so successful that the former steam plant has been abandoned. Either illuminating or producer gas can be used. The electrical plant includes two Westinghouse alternating dynamos of 1500 and 1750 lights capacity, with separate exciters; three 45-light Schuyler arc-machines, and two Schuyler 40-light commercial machines.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

LL probability of the Congreaves Ironworks and the New British ron Company being restarted—at least as regards the manufactured iron and steel plant—seem to be dissipated by the sale which has this week begun of the extensive plant and stock in lots under the hammer. The attendance, which was large, included buyers from Manchester, Sheffield, and other distant centres, and some fair prices were realised. The average price for job lots of iron was, it is suggestive, £4 per ton, and for scrap £2 2s. A large quantity of steel ingots were disposed of at prices ranging from £2 2s. 6d. to £2 7s. 6d. per ton. It is intended to continue the sale at intervals during the autumn, when the mills, forges, steelworks, blast furnaces, chain works, colliery plant, &c., will be sold without reserve. A rumour has been afloat this week that the blast furnaces had been purchased by a syndicate and were to be restarted, but I fear that the report is without foundation.

Business in the iron trade is this week assisted by the continued firmness of the Scotch and Cleveland markets, and by the increased demand which has appeared in some departments of the manufactured iron trade. The sheet iron makers are busier, and so, too, are the galvanisers. The bar makers are doing rather more, and thin hoops and strips are understood to be exceedingly firm. Prices are upheld on the improved basis lately ruling, namely, £6 10s. to £6 12s. 6d. and £6 15s. for black sheets—doubles; £7 5s. for trebles, and £7 to £7 10s. for common plates. Galvanised sheets are £9 12s. 6d. to £9 15s. and £10, f.o.b. Liverpool or equal, and common bars £5 10s., while good merchant bars are £6, and marked bars £7 10s.

The sheet iron works at Walsall of Messrs. Walker, which have been closed since the spring of last year, were re-opened this week—an indication of revived trade of a very favourable sort. Pig iron keeps strong in price for all descriptions, and demand is good.

The declaration of a reduction in colliers' wages of 4d. per day, or stint, by the Coal Trade Wages Board, has led to a strike since last report, at some of the West Bromwich collieries, including the important Sandwell Park Company's concern. Some 8000 colliers are affected by the reduction all over the district, but fortunately not much more than 1000 of these came out, and the strike was of very short duration. The men protested that they should have received a fortnight's notice on Wednesday, but under the rules of the Wages Board this is not so. The men's leaders of the Board did their utmost to persuade the men to return to work, but until Tuesday in vain. On that day, however, the men agreed to descend the pits again on Wednesday, and most of them did so. But it is understood that the advisability of giving notice for a termination of the Wages Board will be discussed in the ensuing few weeks, and instead of joining the National Federation. The experience is a repetition of the old trouble of the difficulty of getting miners to adhere to a sliding scale in a falling market, and is an evidence of the increasing favour which the National Federation is meeting with in Staffordshire. Already 2000 miners here are affiliated with the organisation, and it is probable that before a very great while all will be.

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester.*—The probability to which I previously referred, that the increased weight of buying recently going on in the iron market might prove to be no more than the result of a very general conviction on the part of consumers and merchants that prices had touched the bottom, and that it was therefore prudent to place out the orders and contracts they had been holding back, seems now to be recognised. There is nothing to indicate that users have been buying more iron because they have secured a correspondingly increased weight of work, and I hear of no reports of appreciably increased activity in any of the principal iron-using industries. Merchants who have been buying to cover and consumers who have supplied their present requirements are now holding back from placing further orders at the advanced rates quoted by makers, whilst, on the other hand, makers who are mostly now tolerably well sold for the next two or three months are indifferent about booking orders, except they can get their present rates. The result will probably be another lull in the market until present contracts are to some extent worked off; but the general opinion is that prices are not likely to come back to the exceedingly low figures recently ruling, and with the excessive lowness of stocks, should there be any real revival in the iron using industries which would bring about an enlarged demand on account of actually increased consumption, a considerable further rise in prices is not at all improbable.

About a fair average attendance was brought together at the Manchester ironmarket on Tuesday, but a quieter tone prevailed generally as compared with the last fortnight or so. Prices for pig iron, however, were very strong, makers of some brands holding out for further advances upon the quotations of last week, but there was a disinclination on the part of buyers to follow this further upward move, and any transactions put through at the full quoted prices were for the most part only of small weight. Lancashire makers, who have not advanced their list quotations at all during the recent upward move, report a moderate business, and they are very firm at about 40s. for forge to 42s. for foundry, less 2½ at the works, or equal to about 42s. 6d. for forge to 44s. 6d. and 45s. for foundry delivered equal to Manchester. Lincolnshire makers, who have been selling pretty freely, were asking quite 6d. per ton above last week's prices, but only occasional transactions, and these of no weight, were reported at what may be termed the maximum figures. In forge iron some business has been put through at about 39s. 6d., and in foundry at about 40s. 6d. and even 41s., net cash, delivered Manchester, whilst there have been a good many inquiries within about 6d. of the figures makers have been asking. Makers are now holding out for about 39s. 6d. to 40s. for forge, up to 41s. for foundry, net cash delivered Manchester, and although these figures seem to have checked further buying, makers are not at present at least at all disposed to give way, preferring to work on with the contracts they have secured rather than come down under the maximum quoted rates. In Derbyshire iron there has been a fair amount of business doing recently, and foundry qualities are now quoted about 45s. to 46s., net cash, delivered Manchester. Middlesbrough iron continues very firm at about 45s. to 45s. 4d., net cash, for good foundry brands, delivered Manchester, and a tolerable weight of business is being put through at something like these figures. In Scotch iron quotations are little more than nominal, some brands are altogether out of the market, but in Eglinton business has been readily done at about 48s. 6d., net prompt cash, delivered Lancashire ports.

The manufactured iron trade still shows no really appreciable improvement. Here and there orders have perhaps been coming forward rather more freely during the past week or so, but not sufficient to give anything like activity to forges, which are mostly still short of work, and any stiffening up in prices has been due almost entirely to the increased cost of raw material, which has compelled makers to withdraw from the concessions they were previously disposed to offer buyers where business could be secured. Delivered Manchester district, Lancashire and Staffordshire bars remain at £5 7s. 6d. to £5 10s.; Lancashire and Staffordshire sheets, £7 to £7 5s.; and Lancashire hoops, £5 17s. 6d. for random, and £6 2s. 6d. for special cut lengths.

Nut and bolt makers report rather more business doing, but no really better prices are obtainable.

The steel trade generally continues only quiet. Good ordinary foundry hematites can still be readily bought at 53s., less 2½, delivered Manchester, which is only about 6d. above recent minimum quotations, and even under this figure has been taken upon special sales, but makers in one or two cases are quoting 54s. to 54s. 6d., less 2½, delivered. Ordinary basic billets are still readily obtainable about £4 net cash, and although makers of steel boiler-plates, owing to the stoppage of production in Scotland, are not quoting under £6 7s. 6d. to £6 10s. for delivery in this district, merchants are prepared to book forward orders at about £6 5s.

In the metal market a moderate business is coming forward at the recent advance in list rates for manufactured goods.

A rather more hopeful tone seems to prevail in some branches of the engineering trades, and here and there a little more activity is reported, chiefly amongst machinists and some of the special machine tool makers; generally, however, there is no real improvement, and for the most part establishments continue but moderately off for work, with new orders still coming forward but slowly.

A very handy portable furnace, specially designed for melting magnolia metal, is being introduced by the Magnolia Anti-friction Metal Company, of Manchester. This furnace has been designed with the object of removing all risk of overheating, which s injuriously affects the chemical composition of this metal, and thi is accomplished in a very simple manner. The furnace is heated by gas, through burners so arranged that seven different powers or grades of heat can be obtained by simply opening or closing one or other of three regulating cocks which are provided for this purpose. This enables the metal to be melted in the furnace in from eight to ten minutes if required, by using the whole of the burners, or it may be kept fluid all day by using the smallest burner alone. The top of the furnace is arranged on one side in the form of a wide shelf, underneath which pass the waste gases, and the mandrils, bearings, bushings, &c., can be laid upon this shelf for heating to the proper temperature before the metal is run into them. The furnace, which is made in two sizes, one to hold about 1 cwt., and the other to melt any quantity of metal up to 3 cwt., is light and portable, so that it can be moved to any convenient place in the works, and, by means of a rubber tube, connected up to the nearest gas pipe. By this means there is no risk of the metal cooling down during conveyance from the furnace to the bearing that is being cast, and any ordinary workman can run the furnace without difficulty or danger, whilst he has ample time to get ready the bearings, &c., into which the metal has to be poured.

The coal trade still shows no appreciable improvement, except perhaps rather more inquiry for the better qualities. Pits, however—except where they are in a position to secure shipping orders—are still scarcely working four days per week, whilst stocks are still accumulating. As regards manufacturing classes of fuel, the local demand continues to be restricted by the holiday stoppages in various manufacturing centres; and engine fuel is still more of a drug upon the market, with very low-priced supplies coming in from other districts. At the pit mouth best Wigan Arley coals do not average more than 11s.; seconds, 10s.; common house-coals, 8s.; and steam and forge coals about 7s. to 7s. 6d. per ton, with engine fuel ranging from about 3s. 9d. to 4s. for common, to 4s. 6d. and 5s. for medium, up to 5s. 9d. and 6s. for the best descriptions.

In the shipping trade a fair amount of activity is still reported, with considerable quantities of steam coal and engine fuel going away to Scotland; but no better prices are obtainable, ordinary steam coal not averaging more than 8s. 9d. to 9s., and engine fuel 5s. 6d. to 5s. 9d., delivered at the Garston Docks or the High Level, Liverpool.

For some time past it has been evident that the Lancashire Coal Sales Association, which was established just after the close of the coal strike, with a view of preventing undue competition in the market, had only a very precarious prospect of continued existence, there being strong complaints on the part of some of the leading colliery owners connected with the Association, that not a few of the members in one way or another were underselling the prices agreed to at the meetings; and the withdrawal of several of the largest colliery concerns in Lancashire, at a meeting held in Wigan last Monday, may be said to have brought about the final break-up of the Association, as the other members considered it useless attempting to further carry it on. Whether this break-up of the attempted combination on the part of the coalowners to regulate prices will result in any weakening in the market remains to be seen; those firms who have complained that they have been undersold, and, whilst bound by the official list rates, unable to compete, will of course now be at liberty to take such action as they think best in their own interests, but probably the near approach of winter may tend to remove underselling and give a steadier tone to prices.

*Barrow.*—Another quiet week's business has been done in the hematite pig iron trade. Orders for foreign and continental users are especially few, and prospects of any improvement in trade are remote. Business in Bessemer iron is chiefly confined to local users, and the general home demand is very quiet. Forge and foundry qualities of metal are in very quiet demand. Only thirty-three furnaces are in blast. Prices are steady at 44s. 7½d. net cash sellers, and 44s. 6½d. buyers. Makers are quoting 45s. to 45s. 6d. per ton net f.o.b. for parcels of Mixed Bessemer Nos.

Iron ore has but a very poor market. Locally there is but a small consumption. Less is being sent away by shipping, and the amount used in different parts of the country has been sensibly minimised by the keen competition on the part of Spanish raisers of ore. Native qualities are quoted at 8s. 6d. per ton net at mines, and best samples are in small sale at 12s. to 14s. per ton.

Steelmakers report no further improvement in the state of business. Orders are very scarce for rails, tin-plate bars, hoops, slabs, wire rods, and billets, and there is also a good trade doing in steel shipbuilding material, orders for which are fairly well held. There is not much prospect of new orders at present.

Shipbuilders and engineers report that a few inquiries for new tonnage have come to hand, some of them of an important character. At Barrow during the week two trading steamers, each of about 4000 tons, have been launched, the Axim for the British and African Company, and the Clan Campbell for the Clan Line. Last week the newly-tripled steamer Xema, belonging to the Cork Steampacket Company, made her trial from Barrow, which was very satisfactory.

The coal and coke trades are very quiet, and sales are exceedingly few of late, as well on manufacturing as on shipping account.

It is stated that in the West Cumberland district some marked developments are taking place in the manufacture of coke, which it is expected will tend to place makers of pig iron in a better position than at present, when they are using such a large amount of Durham coke.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

IN the South Yorkshire coalfield the large collieries producing steam coal are working four to six days a-week, and firmness is generally reported. The owners of house-coal pits, however, are not so well off, the demand exhibiting no autumnal influence of any importance, and the tendency of prices being downward. The wages difficulty, as revived by the lads and banksmen, has not yet closed with the suggestion of the South Yorkshire Joint Board—as confirmed even by the Conciliation Board—but is certain to do so. At one large colliery, the New Oaks, the miners' leaders have found that the lads decline to follow their counsel. The surfacemen also express strong dissatisfaction, although they appear to submit for the present to bear grievances quietly. It is admitted that their position is a hard one.

House coal continues in small demand, considering the season is now on when householders lay in stocks for winter. To London the tonnage is not quite up to the average of former years. Buyers evidently expect that values will be lower, and hold off purchasing to any extent on that account. Agents, therefore, find it hard to make sales at current rates. Several of the West Riding towns are securing supplies, it is said, at prices considerably below the average. If there is to be a reduction before October, the existing condition of trade will accelerate the concession by the keen competition for orders. Quotations are now as follow:—Silkstones, 9s. 6d. to 11s. per ton; Barnsley house, 8s. 6d. to 10s. per ton; other qualities, 1s. 6d. to 2s. per ton lower. For steam coal prices appear hardening. Having regard to the advanced season, the trade with the Humber ports is well maintained. The railway companies are also taking a full average. Barnsley hards are 7s. 9d. to 8s. 6d. per ton; lower grades from 7s. per ton. The gas companies no longer hold their hands, there being a decidedly brisker demand at 7s. to 8s. per ton. In manufacturing fuel there is much less demand than supply, prices being weak and tending downward. Supplies are easily secured at exceptionally low rates, good slacks not making more than from 4s. to 5s. per ton; ordinary slack and smudge abundant, and realising about 2s. per ton. Coke remains at 9s. to 11s. per ton.

The steel manufacturers are already feeling the benefit of the new tariff arrangements in the United States, and energetic efforts are being made to recover much of what has been lost in that market. The new duties, however, are not operating altogether as expected, the broad effect being that cheap manufactures benefit by the change from the specific to the *ad valorem* system, but with regard to the higher-priced productions the very opposite is the case. Several articles which are not made in the States, and could be successfully imported from Sheffield, are hindered rather than helped by the new scale, owing to these articles, being high-priced, having now to pay a heavier amount, the *ad valorem* duty being more than the specific duty per pound weight. The cutlery trades are generally benefitting by the change.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

It is satisfactory to be able to announce the removal of one obstacle which has done very much to retard business in this district for weeks past, in fact it has paralysed operations at many works. The strike of moulders is at last at an end, the men resuming work on Monday wherever the employers were in a position to find it for them, but in a large number of cases the men will have to remain idle for an indefinite period because work has had to be sent elsewhere during the strike, and orders which would have been executed in this district have had to be completed in other parts of the country and even abroad, the consumers being unable to wait the convenience of manufacturers in the North of England. Thus when the men are anxious to work and have given in, they in many cases find there is no work to do, business being driven away by their action. The men have not abandoned their claim to advanced wages, but they have agreed to the proposals of the employers that they should go back to work at the old rate of wages, and submit their claims to an Arbitration Court which is to be established. The men have been on strike twenty-four weeks, and their first claim was for an advance of 3s. per week in time wages, and 10 per cent. in piece prices, but they modified their claims to 2s. and 5 per cent. respectively, before the strike actually commenced on March 11th, and that they still claim. But recently the employers have found it necessary on account of the increased dulness and unprofitableness of trade caused by the men's action, to put in a claim for a reduction of wages, and the arbitrators will be called upon to adjudicate upon that claim as well as upon the claim of the men for an advance. The dispute would have been ended before, but the men objected to anything but their own claim being considered. It is also provided that a Conciliation Board shall be formed in order to adjust all future labour disputes. The patternmakers have not abandoned their strike, but they are comparatively few in number, and it is expected that they will quickly follow the example of the moulders. They adhere to their original demand for 3s. 6d. per week on weekly wages and 10 per cent. on piece prices. This strike of moulders has done a great deal of harm to the trade of the district, for though 1500 men only were directly involved in it, their action threw out of employment nearly 20,000 other operatives, who cannot meet with full work for some weeks yet. The cessation of this strike has had a very favourable influence upon the market generally, and has allowed of consumers ordering more freely than for a long time past, the demand being best for steel plates and angles, and it is reported that several good orders for steamers have been concluded in this district this week.

Manufacturers of finished iron and steel have had their position so much improved by the termination of the moulders' strike, that they have been able to advance their prices, and competition among them is less keen. They have for some weeks had to seek for orders to replace those the execution of which was suspended owing to the strike. But now they can resume work on these old contracts, and thus are under less necessity to look out for others, and accordingly have raised their prices. Steel plates and angles have this week been raised another 2s. 6d., and thus are 5s. above the recent minimum. Makers expect to be able to realise still better prices, as the shipyards get more fully to work and can take more of their iron. Steel ship plates are now £5 2s. 6d.; steel ship angles, £4 17s. 6d.; steel boiler plates, £6 2s. 6d.; and steel engineering angles, £5, all less 2½ per cent., and f.o.t. Iron plates and angles are in rather better request, and are quoted at somewhat higher figures. Iron ship plates are at £4 17s. 6d., and iron angles at £4 15s., both less 2½ per cent., and f.o.t. In consequence of the improvement in the steel plate and angle trade, the consumption of hematite pig iron, which has for a long time past been poor, has increased, and makers will now be able to reduce the heavy stocks they are said to hold. They have kept up their make while the consumption declined, through the stoppage of local steel works and the smaller requirements of Scotland. Thus the stock accumulated, and on this account they have not been in a position to advance their quotations so much as have the producers of ordinary Cleveland pig; in fact, the advance in Middlesbrough hematite pig has only been 3d. from the minimum, whereas for No. 3 Cleveland pig it has been 1s. Mixed numbers of East Coast hematite pig can yet be bought at 43s. per ton for early delivery. Last month the closing of local steelworks caused the stock of hematite pig in Connal's public warrant stores to increase 12,441 tons, the quantity held at 31st ult. being 55,758 tons. No particulars are available as to the quantity the producers have in their own yards, as the ironmasters do not give the stocks of hematite and basic iron, though they have for years published the stocks of Cleveland iron.

The August statistics of the Cleveland Ironmasters' Association were unsatisfactory, but not more so than was expected, seeing that the moulders' strike in this district and the miners' strike in Scotland have greatly reduced the consumption of Cleveland iron. It was calculated that the stocks would show an increase of 10,000 to 12,000 tons, and the actual increase was 13,298 tons, making an increase of over 30,000 tons in the last three months, a period when there should have been as large a decrease, but the situation has been exceptional because of the strikes, and an improvement may now be expected. That the trade do not look upon the statistics unfavourably is seen by their having no influence on the market; they relate, however, to the past, and a new order of things has been inaugurated this month. The returns show that there were no changes in the furnaces last month, 51 making Cleveland iron, and 43 hematite, &c., total 94 blowing out of 142 erected as in July. The production showed a decrease of 8260 tons from July, which may be accounted for by the holiday which the blast furnacemen took on August 11th. Of Cleveland pig 116,985 tons were made—6129 tons decrease from July—and of hematite, basic, and spiegel iron 127,386 tons—2131 tons decrease—total 244,371 tons—decrease 8260 tons. The total stock of Cleveland pig iron held on 31st ult. was 186,709 tons, of which 91,055 tons was held unsold by makers — increase 14,266 tons, and 90,389 tons in Connal's warrant stores—decrease 5003 tons. The pig iron shipments were poor, reaching from Middlesbrough only 75,723 tons, this being 10,805 tons less than in July, 1894, and 13,575 tons less than in August, 1893. The exports oversea were up to the average, and the falling off was entirely due to the strike in Scotland, which led to a great decrease in the Scotch consumption of Cleveland iron.

The prospects of the Cleveland pig iron trade are more satisfactory, and prices continue to improve. No. 3 G.M.B. has been quoted and sold this week at 36s. 4½d. for early f.o.b. delivery, but the best brands have not been under 36s. 6d. Some No. 3 has been sold for delivery up to the end of the year at 36s. 6d., but not many producers will accept that under present circumstances. Cleveland warrants have not fluctuated much this week, sellers keeping about 36s. 4d. The lower qualities of Cleveland pig iron are creeping up in value, as there is more demand for them now that the moulders' strike has ended, and the Scotch strike is in a fair way for collapsing. No. 4 foundry is at 35s. 3d., and grey forge at 34s. 6d., but notwithstanding the advance they are still relatively cheaper than No. 3.

The rail trade is very quiet yet, though it is, perhaps, a little better than it was. For heavy steel rails £3 10s. net at works is quoted. Common iron bars are at £4 17s. 6d., less 2½ per cent., f.o.t., and thus have improved very little in value for weeks. Engineering establishments will now be able to work more fully, because there will no longer be any stoppages owing to the difficulty of getting castings, now that the moulders have gone in. The marine engineers, it will be remembered, struck work at the same time as the moulders, and for a similar advance, but they abandoned their claim before long. That, however, has not availed them much, because their employers could not set many to work as long as there was a dearth of castings. Some masters nevertheless, in spite of the opposition of the moulders, have been able to procure castings from other districts, and considerable quantities have been obtained from abroad. Increased activity cannot but follow, in the engineering industry, the settlement of the difficulty in the ironfounding trade.

The coal trade continues very active, and both Durham and Northumberland are profiting considerably by the Scotch miners' strike, as from these districts a good deal of fuel is sent to Scotland itself, and more is forwarded to consumers abroad, who have hitherto bought largely from Scotland. Best Northumberland steam coal is at 10s. 9d. to 11s., f.o.b. Coke is in good request at 12s. 6d. per ton, delivered on Tees-side.

The colliery mechanics of Northumberland have voted against the acceptance of a reduction of 2d. per day in their wages, unless it were accompanied by the 53 hours per week. The coalowners are not likely to grant this concession, though the Durham coalowners gave it to their mechanics three years ago. The Durham miners have voted against the rules which the masters and their own executive propose for governing the Conciliation Board which is to be established, and the question is to be further considered.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

The pig iron market has been comparatively active, a large quantity of warrants changing hands in the course of the week. The prices have fluctuated somewhat, but the general tendency is upwards. The Scotch warrants have sold from 43s. 6d. to 43s. 7d. cash. There has been little doing in hematite iron, the local consumers still having their works closed, and Cleveland is only in small request from the same cause.

Two furnaces have been put out of blast at Shotts, leaving two in operation there, and two at Coltness, these four now being all that are at work in Scotland. Special brands are becoming scarce, some of the makers having nothing to offer. Both Gartsherrie and Clyde have disappeared from the market lists.

The makers' quotations are therefore very firm:—G.M.B. f.o.b. at Glasgow, No. 1, is quoted 45s. per ton; No. 3, 44s.; Monkland, No. 1, 48s. 6d.; No. 3, 44s.; Carnbroe, No. 1, 48s. 6d.; No. 3, 46s. 6d.; Calder, No. 1, 58s.; No. 3, 50s.; Summerlee, No. 1, 56s.; No. 3, 50s.; Coltness, No. 1, 59s.; No. 3, 52s. 6d.; Glengarnock at Ardrossan, No. 1, 56s.; No. 3, 50s.; Eglinton, No. 1, 54s.; No. 3, 47s. 6d.; Dalmellington at Ayr, No. 1, 52s.; No. 3, 47s. 6d.; Shotts at Leith, No. 1, 56s. 6d.; No. 3, 50s. 6d.

The stocks of pig iron in the Glasgow warrant stores have been steadily decreasing, and now amount in the aggregate to 302,000 tons, being 34,000 less than at this time last year.

The shipments of pig iron in the past week have been 2978 compared with 5123 tons same week last year. There was sent to Canada 250 tons, India 209, Australia 210, France 10, Germany 129, Holland 815, Spain and Portugal 266, China and Japan 100, other countries 160; the coastwise shipments being 839,000, compared with 2283 in the corresponding week.

The manufactured iron and steel trades are still very dull.

The position of the coal trade shows little change.

The result of the ballot of miners taken towards the close of last week gave a majority in favour of what are known as the Federation terms, viz., an advance of 6d. per day, with wages guaranteed for two years. This resolution was carried against another proposing to adhere to the demand for 1s. per day, and is therefore a modification of the miners' original demand. The employers are not, however, disposed to make any concessions whatever.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

Last week the sailors' strike was to the front at Cardiff, Newport, and Barry, and some believed that a great time of excitement and of trade blocking was at hand. So far there has been very little hindrance to business, and several cases have occurred of steamships and sailers getting crews at union rates. The fact would seem to be that, where freights have sanctioned it, shipowners have given way. The coal trade has been vigorous of late, and prices have been sustained. Had it been on the down grade, as was anticipated, it is not likely that any shipowners would have yielded, but would have resolutely abided by their determination to put their vessels by rather than give way. If, as some contend, the rate of wages is really lower in Cardiff and Newport than at Swansea, where there is no dispute, no doubt an investigation will be made, and matters remedied as much as possible. But it is here where the union and shipowners are at variance. The union demands a fancy wage; the coalowners and shipowners contend that the wage must be governed by the freight they are able to get.

For the Mediterranean, freights at Cardiff this week showed a slight hardening tendency; those for France are unaltered.

Coal shipments at all ports have kept up well.

Closing prices at Cardiff remain as follows:—For best steam, 11s. 3d. to 11s. 6d.; seconds, 11s.; dry sorts, 9s. 9d. to 10s. 3d.; small, 5s. 3d. to 6s.; according to quality. The slight droop in house coal has been regained, and best house commanded 11s. No. 3 Rhondda is selling at 10s. 6d.; brush 8s. 6d.; small, 6s. 6d. No. 2 Rhondda is at 8s. 6d. to 8s. 9d.; through, 7s.; small, 4s. 6d. to 5s.

The improvement which has been manifested in the coal trade has had the usual improving influence all round. Markets are much more buoyant, and a good deal of business has been done in coal and iron shares, the prominent ones in demand being Albions, Norths, Penrhiwkiber, and Rhymney coal. In railway stock, Taff Vales are brisk, and business has been done at 83. Debenture stock, up 1½. Rhymney Railway rise strongly maintained; present figures, 202. Barrys remain 230. Vale of Glamorgan shares are at 18s. premium.

Patent fuel is in improved demand, especially at Swansea, which exported over 10,000 tons last week. At Cardiff prices are maintained 11s. to 11s. 6d. Coke also remains firm, furnace selling at 15s. to 16s.; good foundry, 17s. to 17s. 6d.; and special, 20s. to 20s. 6d. Pitwood, 15s. 6d.

On 'Change, Cardiff, this week there was an improved tone for foreign ore, and the following prices were quoted:—Best Rubio, 11s. to 11s. 3d.; Tafna, 10s. 6d. to 10s. 9d.; Garucha, 10s. 6d.; Perman, 9s. 6d. to 10s.; and Almeria Campanil, 14s. 3d. per ton, c.i.f. Newport or Cardiff.

A little more activity is reported from the principal iron and steel works.

Cardiff Exchange tin-plate quotations this week were:—Steel cokes, J.B. brand, 10s. 9d. to 11s.; B.V. grade, 10s. 6d. to 10s. 9d.; Bessemer cokes, 10s. 6d. to 10s. 9d.; Siemens coke, 10s. 9d. to 11s. Siemens cokes, squares and odd sizes, 11s. 3d. to 11s. 9d. Siemens charcoals, upper forest grade, 11s. 6d. to 11s. 9d. Siemens charcoals, 12s. 3d. to 12s. 9d. Siemens best charcoals, 13s. 3d. to 13s. 9d. Worcester grade Siemens ternes, 28 by 20, 23s. 6d.; Dean grade ternes, 28 by 20, 22s. to 23s. The above quotations are all I.C. 95 lb. to 100 lb.; cokes, 3 lb. less than I.C., and 90 lb. cokes 4 lb. less than I.C. all delivered f.o.b. Wales.

Swansea Exchange quotations mid-week were: Glasgow warrants, 43s. 6d. cash; Middlesbrough, No. 3, 36s. 3d.; Welsh bars, £5 to £5 2s. 6d.; sheet iron and steel quotations unchanged; heavy rails from £3 17s. 6d.; light, from £4; Bessemer bars, from £4 2s. 6d.; Siemens, from £4 5s.; Bessemer tin-plate cokes from 10s. 6d. to 10s. 9d.; Siemens, 10s. 9d. to 11s.; ternes, from 20s. to 24s.; best charcoal, 12s. to 12s. 6d.; wasters, 6d. to 1s. less than primes; odd sizes, usual extras.

It is again affirmed, with some show of official authority, that an agreement is on the point of being signed between the Great Western Railway and the Swansea Harbour Trust, by which the railway rates to that port will be materially reduced. It is stated that the arrangement will come into force in a very short time.

The No. 2 Rhondda seam has just been struck at the Glyncymmer Colliery, Maesteg. It is 3ft. thick and of good quality. Mr. T. G. Davis, M.E., conducted the operations.

The Junior Engineering Society were much gratified by their inspection of the Taff Vale locomotive works Cardiff, the Alexandra Docks, Newport, the Lloyd's proving house, Cardiff, and various places of interest.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

The iron markets over here continue remarkably quiet. So far as both makers and consumers are concerned, a general want of confidence in the future in most cases operates against entering into forward engagements of any moment, and until the outlook becomes more settled business is likely to remain of a hand-to-mouth sort.

There is still an absence of improvement in the Silesian iron trade, and if there is any change noticeable it is rather in the direction of a weaker tone in the market, both for crude and for manufactured iron. The wire and nail-shops are comparatively well employed. List quotations do not show a change since former letters, being in the same depressed condition as before; there have even been symptoms of a downward inclination in some instances.

Though there is not much animation noticeable on the Austro-Hungarian iron market just at present, business transactions are nevertheless considered as fairly satisfactory. Bars, girders and all sorts of plates are in quiet but regular call. In Bohemia English plates are being offered at very low rates, and inland firms find it extremely difficult to compete with their foreign rivals.

The French iron market is still rather uncertain, but, on the whole, better this week than last. In pig iron there is not much doing, but quotations are tolerably well maintained for most sorts. Manufactured iron makers remain fairly satisfactorily employed; there is a considerable amount of new work coming forward in the girder line, and a firm tone is to be perceived in the prices for that article. Bars are still offered at 155f. p.t.; while girders continue to be sold at 165f. p.t.

In Belgium the iron industry remains very dull, but there is, nevertheless, a slightly improving tendency to be noticed in some branches. Plates and steel girders, for instance, have experienced quite a fair request upon the week. The prices obtainable leave much, or rather everything to be desired; even the smallest export orders cannot be got unless large reductions are agreed to. Demand and sale remain limited on the Rhenish-Westphalian iron market, and the general tone is altogether very sensitive and uncertain, so that even the most experienced member of the trade would hardly be able to form an opinion as to the future development of the iron business. Iron ore is in moderate request, and the prices paid for spathose iron ore, are M. 7·40 to 7·90 p.t.; roasted do., fetching M. 11 to 11·50 p.t. at mines. Inferior qualities are paid with M. 9·80 to 11 p.t. Luxemberg-Lorraine minette is in tolerably good demand, and quotations are, with few exceptions, pretty firm, ranging from M. 2·50 to 3·20 p.t. net at mines. Spanish ore has improved in demand. In the Rhenish-Westphalian district the quietness in the pig iron trade is as great as ever, while from the Siegerland rather more cheering reports come in. Spiegeleisen is sold at the old price of M. 52 p.t., while Rhenish-Westphalian forge pig No. 1 continues to be quoted M. 46, No. 3 M. 40 p.t. at works. For hematite M. 63 is given; foundry pig No. 1 stands at M. 63 p.t., while No. 3 costs M. 54 p.t. Basic is noted at M. 45 p.t. Luxemburg forge pig continues to be offered at 48f. per ton free Luxemburg. The demand on the malleable iron market has been irregular, some mills being well off for new work, while others hardly know how to keep their concerns going. Stocks are, on the whole, decreasing rather than otherwise; quotations remain low. Orders for sectional iron are pretty numerous, and hoops have likewise been in good demand, but for both articles prices remain depressed. Concerning the plate and sheet trade there is still nothing of importance to notice; for export extremely little has been doing, and unless foreign trade becomes more lively there is not much to be expected with regard to higher prices. For the present very low rates are the rule. The majority of the foundries and machine factories are well employed, and the wagon factories are looking forward to a time of vigorous activity, an order for 354 passenger cars and 220 load wagons having just been given out by the Elberfeld Railway Administration.

Latest list quotations per ton at works are as under:—Good merchants bars, M. 110; angles, M. 120; girders, M. 95; hoops, M. 110 to 115; billets, in basic and Bessemer, M. 81; heavy plates, for boiler-making purposes, M. 150; tank ditto, M. 130 to 135; steel plates, M. 125; sheets, M. 140; Siegen thin sheets, M. 125 to 130. Iron wire rods, common quality, M. 115; drawn wire in iron or steel, M. 105 to 120; wire nails, M. 125; rivets, M. 150; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 115; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230; light section rails, M. 95.

At a Vienna workshop an iron church is being constructed for the Bulgarian colony at Constantinople. The basis of the church, which is to hold 500 persons, measures about 55 metres; the iron used weighs 400 t., while nearly four million rivets and screws are required. Sixty-four pillars bear the roof. It was first intended to have the inside of the church covered with fayence and marble plates, but that plan has been abandoned, and bronze-gilt iron has been chosen instead. The total cost of the church is estimated at 250,000f.

The Explosion in the Solent.—Colonel Ford, her Majesty's Inspector of Explosives, in reporting upon the explosion of tonite or cotton powder, which resulted in the loss of seven lives on a boat in the Solent on July 19th, considers that the explosion was caused either by Alfred Rennie, a seaman apprentice, attempting to remove the detonator from a 20lb. charge which had failed to explode, or by the charge being knocked off the thwart by one of the men, the latter cause being the less probable. Further, the successive steps leading up to the accident appear to have been all more or less blameworthy or open to criticism. In the first place, Mr. Gaster, over-estimating his knowledge of blasting operations, proposed that he should conduct the work, and incorrectly reported that he had all that was necessary for carrying it out. Then, the Trinity House, accepting his rating of his qualifications, authorised him to conduct it without being satisfied that he was competent to do so. Colonel Ford adds that in the course of his inquiry it came to light that the Trinity House had habitually stored tonite in lightships without any licence, this being a practice not in accordance with the Explosives Act.

## AMERICAN NOTES.

(*From our own Correspondent.*)

New York, August 30th.

American markets are slightly stronger in all lines. Stocks of goods of all kinds, including raw material for manufactures, have been allowed to run very low. Throughout the Western and Southern sections of the country a demand for prompt shipment of seasonable goods is made. Bank loans also indicate the moderate improvement in progress. Jobbers report encouraging inquiries. Money is in good supply. No gold exports for a week. Manufacturers have not bought freely yet. In the iron trade orders were placed for 20,000 billets, 6000 tons rails, and quite a number of small orders for plate and structural material. There is confidence in further improvement. Agricultural works, foundries, wire mills and rolling mills are more fully engaged than for many months. Blooms are 19 dols., girder rails 23 dols. to 25 dols. The trade is ready for a sudden demand, and it is a widespread belief that an improvement will soon show itself. Prices have never been as low. Labour strikes are threatened in three or four leading industries, involving 50,000 hands, because of reductions made necessary by tariff reductions.

## LAUNCHES AND TRIAL TRIPS.

A new twin-screw steamer, the Columbia, built by Messrs. James and George Thomson, Clydebank, to the order of the London and South-Western Railway Company, for their fast passenger and mail service between Southampton and Havre, was launched on Tuesday, the 4th inst. The length of the vessel is 270ft. between perpendiculars, and the breadth 34ft., the gross tonnage being about 1100 tons. In the design of the vessel the first care has been to provide exceptionally comfortable accommodation for passengers during the night service across Channel, and the first-class passengers will have separate staterooms similar to those in ocean-going steamers. One hundred passengers can be accommodated in this way, chiefly in state-rooms containing two berths, while there is accommodation in large cabins for fifty second-class at the other end of the vessel. The machinery is so arranged that the majority of the first-class state-rooms are situated as nearly as possible in the centre of the vessel, where the pitching motion is least, and bilge keels have been fitted in order, as far as possible, to prevent rolling. The steamer will be propelled by two sets of four-cylinder triple-expansion engines, and a high rate of speed is expected.

Messrs. Napier, Shanks, and Bell, Yoker, Glasgow, launched, on Monday, the steel screw steamer, Independencia, built to the order of Messrs. Frame, Alston, and Co., of London, for the Government of San Domingo. The vessel, which has yacht lines and cutwater stem, has been designed by the builders, and constructed to Lloyd's 100 A1 class, to meet the views of the President as a means of coast defence along the shores of San Domingo. To meet this requirement, the vessel will be fitted with seven Hotchkiss guns placed at convenient positions around the deck. Her dimensions are: Length, 170ft.; breadth, 25ft.; depth, 12ft. 6in. The entire space aft of machinery is set apart for the President's suite of rooms, which will be furnished in first-class style, the furniture being in walnut. At the forward end of the machinery space the officers and artillerymen are berthed in rooms branching off a well-arranged mess room; while the crew are housed in a good-sized forecastle. The Independencia throughout will be fitted with a complete installation of electric light, including a powerful search light, and, in addition, supplementary candle lamps will be supplied to the rooms. The deck gear consists of steam windlass, steam steering gear on bridge, and screw gear and capstan aft. Double awnings will be provided right fore and aft, and over bridge. The vessel has been constructed under the supervision of Mr. George McFarlane and Mr. Nicol MacNicoll, of Glasgow.

On Saturday, September 1st, the pleasure steamer Duke of York was successfully launched from the Thames Electric and Steam Launch Works, Eel Pie Island, Twickenham. Miss Victoria Grant Duff, daughter of Sir Mount Stuart Grant Duff performed the ceremony of naming the boat. The principal dimensions of this vessel are as follows:—Length from stem to taffrail, 80ft.; beam, 14ft.; depth, moulded, 7ft.; draught aft, 3ft. 6in. There is a promenade deck the whole length between the fore and after decks, supported at each end by ornamental steel columns, the side being of teak down to the covering board, and glazed with bevel-edged plate glass. The top of promenade deck is covered with corticine, and the skylights form seats. Galvanised stanchions and steel rails are fixed round. The main saloon is artistically decorated, brass electroliers being fitted for the incandescent lamps. The electric light is also fitted throughout the vessel, the current being obtained from a 50 volt circuit, other lamps being arranged in the port, starboard, and mast head lights. The vessel is propelled by a three-bladed screw, made of Bull's metal, supplied by the Phosphor Bronze Company, and the engines are compound surface-condensing, manufactured in the company's engineering shops. The boiler is of the return tube type, working at a pressure of 140 lb. to the square inch. This vessel has been designed by Mr. W. I. Sargeant, to give a speed of nine knots an hour, for passenger service between the new lock at Richmond and Hampton Court Palace, being the largest launch running on the Thames above lock. There is accommodation for 300 passengers. After the ceremony of launching, the new vessel, with a company of over 200 people, was towed round Eel Pie Island by the electric launch Glow-worm.

Rolling mills and arsenals are being built at Hanyan, China, which will cover seventy acres. Native iron will be used and rails and small arms made on large scale. The rails will be used for local railways.

## RAILWAY CONNECTION WITH MANSFIELD.

Mansfield, a thriving town in Nottinghamshire, is near the line of the Lancashire, Derbyshire, and East Coast Railway, but is not touched by it. The inhabitants, with the people of Mansfield, Woodhouse, and other villages, are anxious to be connected with the main line by a branch, and at a meeting held last Friday night, presided over by the Mayor of Mansfield, a resolution to that effect was passed and a petition adopted for presentation to the directors.

On Monday the Midland Railway Company opened its new warehouses and stores at the Wicker, Sheffield. In 1875 the company laid down at Wincobank, near Sheffield, 3¾ miles of sidings on the down line and 2½ miles on the up line at Grimesthorpe. There, too, was built an engine shed capable of accommodating some forty-eight engines, and a large warehouse of four floors was erected in the Wicker at a cost of £30,000.

The two upper floors of this warehouse, which are used for the storage of grain, sustain a weight of 3000 tons, and hold on each floor 25,000 full sacks. This warehouse, which is fitted with hydraulic machinery, is the only building connected with the old Wicker Station that has been left. In 1892 it was found necessary to make further provision, and the directors decided to spend about £120,000 in the erection of new offices, warehouses, &c. They front Savile-street, cover an area of 650 square yards, are built of red brick, relieved with terra-cotta, and consist of three separate floors, for correspondence and other offices, all lit by the electric light.

The new warehouse, which is connected with the offices by balcony and bridge, consists of basement, ground floor, and upper floor. The basement is used for the storage of wines and spirits under bond, and ale in casks. It has an area of 5500 square yards. There are three large vats for blending spirits. In the two floors there is a total area available for general storage of about 8200 square yards. About 2000 tons of iron, all of English make, has been used.

The electric light installation consists of three single-cylinder horizontal engines, by Messrs. Marshall and Sons, Gainsbrough, two indicating 80-horse power each, and one 30-horse power, four 35-light arc dynamos of the Thompson-Houston pattern, and one incandescent dynamo for 300 16-candle power lamps, by Mather and Platt. The incandescent lamps are for the offices, and in the Wicker warehouses and yard of the engine shed, Cardigan and Grimesthorpe sidings, will be over 110 arc lamps, each of 2000-candle power.

## ELECTRIC GENERATING STATION AT BAZACLE, TOULOUSE.*

By P. Juppout.

The Garonne at Toulouse crosses two weirs, the second and more important of which provides the power made use of in the new generating station here described, which is a central station distributing current both for lighting and for motive power. The head of water is 14ft. 9in., and the hydraulic installation had to be so arranged as not to interfere with the mills already using the water power of the fall. Four turbines of the Girard type were erected, each being able under the full head to develope 320-horse power. The power is under control by means of cast iron valves sliding across the fourteen orifices on each turbine; these are worked either by hand or from two auxiliary turbines provided for the purpose. The turbine shaft is vertical, and drives by bevel gearing—wood and iron—a horizontal shaft, from which a belt is taken to the dynamo.

The demands for power have so much increased that steam engines have had to be provided also, which can be coupled at will to the same dynamos. Soapy water is used for lubricating the footsteps of the turbines, and gives satisfaction.

The dynamos are six in number, made by Messrs. Guénod and Sautter, of Geneva. The current is continuous. At a speed of 380 revolutions each developes a current of 700 ampères at 150 volts. Each turbine, with its two dynamos, will supply twelve thousand lamps. The three-wire system of distribution is used.

In order to maintain a constant electromotive force at the end of the line, the speed of the turbines is regulated to suit the consumption, and the moving masses being large, this method avoids any sudden change, such as might be a danger in directly varying the magnetic field for the purpose of regulation. The entire control of both mechanical and electrical apparatus is concentrated at one point under the eye of the electrician in charge. Eight feeders have been established, all overhead lines, with a development of thirteen miles, and within a radius of 1300 yards from the station.

In order to cope with the increased demand, which went very soon beyond the amount of current originally provided for, two accumulator stations have been established, and a third is projected. These are charged by isolating one of the feeders from the general system at a time when the demand is slack.

The municipality have adopted the company's current for street lighting, there being now two hundred and eight arc lamps in use. They are suspended over the centre of the street from a pair of posts in the line of the kerbs. The motors supplied by the current vary from ½-horse power to 4-horse power, and the price paid is £20 per horse-power per annum. 125-horse power in all is supplied. The total receipts for light and power in 1892 amounted to nearly £24,000.

The s.s. Islam.—The s.s. Islam, which was recently seized on a warrant issued by the British Government, has been fitted by Baird, Thompson, and Co. with a ventilating system which is capable of changing the whole atmosphere of the ship once every minute, if necessary. It can be used with closed hatches and when everything is battened down.

16,288. Joint for Folding Shafts, W. E. Goodwin, Longport.
16,289. Game of Skill and Apparatus, J. F. Parsons, Bristol.
16,290. Face-plate for Tiring Wheels, H. and C Atkinson, Castleford.
16,291. China Pianoforte Keys, E. P. Hutchinson, London.
16,292. Lubricating Hydraulic Rams, W. Entwistle, Manchester.
16,293. Cycles, R. M. McDonald and A. McDonald, Glasgow.
16,294. Frost Hobnail for Roughing Boots, J. Hill, Stourbridge.
16,295. Gas Burners, G. Bray, Bradford.
16,296. Solking and Heeling Boots, T. McCulloch, Bradford.
16,297. Reflecting Gaslights, G. Bray, Bradford.
16,298. Reaping Machine Conveyor, W. Anderson, Glasgow.
16,299. Preventing Air Escaping from Tires, T. Coppock, jun., Manchester.
16,300. Anti-nicotine Plug for Pipes, J. J. Duffy, Dublin.
16,301. Metallic Socket for Picks, G. S. Waterfall, Sheffield.
16,302. Wall and other Decoration, W. A. Ebel, London.
16,303. Pouring Liquids into Vessels, H. Child, London.
16,304. Plummet and Ground-bait Box, W. Wilcox, Wolverhampton.
16,305. Veneer Barrels, C. Wittkowsky, London.
16,306. Bodice Steels, W. Higgs, London.
16,307. Food Safe, E. Paul, London.
16,308. Combination Revolver and Dagger, E. Paul, London.
16,309. Cycle Mudguards, H. Davis and P. Byrne, London.
16,310. Apparatus for Lighting Matches, H. Thurlow, London.
16,311. Oil Stove Flues, J. Harper and Co. and C. Retallack, London.
16,312. Mortising and Routing Machines, A. Slater, London.
16,313. Protecting Cyclists from Dogs, S. Franken, jun., London.
16,314. Railway Carriage Coupling, L. F. D. Saget, London.
16,315. Commode, F. J. Mockler, London.
16,316. Spiked Heel Plates for Boots, H. A. Dightam, London.
16,317. Blackboards for Schools, &c., P. Kohler, London.
16,318. Blind Rack, H. Micklefield, London.
16,319. Construction of Elastic Tires, A. Grupe, London.
16,320. Process for Manufacturing Chlorine, E. Bückse, London.
16,321. Corsets, E. W. Butler, London.
16,322. Portfolios for Binding Periodicals, S. Honeyman, London.
16,323. Game and Apparatus Therefor, W. H. Keene, London.
16,324. Yarn Winding Machines, H. L. Pratt and C. T. Upton, London.
16,325. Cushions of Billiard Tables, W. E. Bartlett, London.
16,326. Construction of Panoramic Scenes, J. Train, London.
16,327. Sanitary Pails, V. E. Poppens, London.
16,328. Combination Apparatus, G. H. Conroy, London.
16,329. Enabling Doors of Hansom Cabs to be Opened and Closed by the Driver, J. G. Price, London.
16,330. Scissors, B. Amsberg, London.
16,331. Electric Organs, P. R. Harrison, London.
16,332. Roofing and Wall Tiles, W. W. Morris, London.
16,333. Velocipedes, A. F. Spencer and A. H. Spencer, London.
16,334. Cleaning Device for Fire-arms, W. Wesenkoff, London.
16,335. Pneumatic Tires, R. Pritt, London.
16,336. Pneumatic Tires, J. H. Price, London.
16,337. Adjustable Slide Rest Attachment for Lathes, H. B. Newbold, Manchester.
16,338. Parcel Carriers, H. A. Dale, London.
16,339. Means for Teaching Music, A. J. Pratt, London.
16,340. Means for Teaching Music, A. J. Pratt, London.
16,341. Beer Engines, W. F. P. Clayton, London.
16,342. Production of Metallic Carbides, G. B. Ellis.—(*T. L. Willson, United States.*)
16,343. Edging for Lace, S. Borton, London.
16,344. Fastenings for Window Sashes, A. E. Dawes, London.
16,345. Window Sash Fasteners, F. W. Cashmore, London.
16,346. Lamp Chimneys, A. L. and G. Ollendorff, London.

28th *August*, 1894.

16,347. Chairs, A. J. Boult.—(*J. Bergmann, Germany.*)
16,348. Machines for Milling, H., S. and B. Preston, London.
16,349 Troughs of Doubling Frames, T. Guest and T. Brookes, Manchester.
16,350. Stiffening for Coat Fronts, T. H. Brown, Manchester.
16,351. Pants, T. H. Brown, Manchester.
16,352. Air-pumps, E. Lyons, London.
16,353. Bonnet Fasteners, A. Smith, Reading.
16 354. Sewing-machine Attachments, J. Knox, Manchester.
16,355. Lighters, R. Neuss, Manchester.
16,356. Tipping Machinery for Trams, B. Nicholas, Pontypool.
16 357. Bed Guard, E. E. Meade and F. W. Gallagher, Ramsgate.
16,358. Hand-lever Lifting-jacks, G. R. Postlethwaite, Birmingham.
16,359. Tie-holder, A. Taylor, London.
16,360. Angle Plate Chuck, H. Venables, Burton-on-Trent.
16,361. Gun and Rifle Slings, C. E. Greener, Birmingham.
16,362. Knife Apparatus, J. E Hayward and J. B. Lowe, Birmingham.
16,363. Producing Patterns on Wood, A. E. Frisby, Nottingham.
16,364 Dress Holders, R. Rees, London.
16,365. Props for Mines, W. W. Barnes, Cumberland.
16,366. Heat Electric Alarm, R. Brown. Preston.
16,367. Window Clip, A. Mokaiesh, Manchester.
16,368. Table Lamps, C. Meason, Birmingham.
16,369. Hanging Lamps, C. Meason, Birmingham.
16,370. Apparatus for Stamping "Set Pots," J. Shepherd, Bradford.
16,371. Corliss Valves, G. N. and A. Brearley, Bradford.
16,372. Stoppers for Bottles, F. A. Walton, Birmingham.
16,373. Lamp Stoves, G. Salter, Birmingham.
16,374. Securing Labels, W. Holland, jun., Birmingham.
16,375. Quick-firing Guns, A. and H. Normanton, Manchester.
16,376. Manufacture of Inlaid Linoleum, D. E. Thomson, Glasgow.
16,377. Coating of Metals, W. T. Leyshon, Birmingham.
16,378 Ventilating Fans, H. T. Johnson, Manchester.
16,379. Apparatus for Cutting Fabrics, J. J. Mann, Manchester.
16,380. Droppers for Wire Fencing, J. T. Rae, Glasgow.
16,381. Quick-drying Paint, J. McLintock, Barnsley.
16,382. Dry-sand Moulding, W. C. Wood, London.
16,383. Operating Vehicle Hoods, H. Golbransen, London.
16 384. Apparatus for Extracting Corks, F. Jorgensen, London.
16,385. Thread-cutters for Sewing Machines, J. Y Johnson.—(*The Willcox and Gibbs Sewing Machine Company, United States.*)
16,386. Automatic Locking Gear, F. H. Nalder and A. Soames, London.
16,387. Smoothing Irons, T. Smith, London.
16,388. Machine for Carving a Fowl, G. C. Nobile, London.
16,389. Grapnels for Lifting Cables, J. Skinner, London.
16,390. Umbrellas, &c., J. P. O'Donnell.—(*F. Giles, Australia.*)
16,391. Electrical Switches, W. P. Theermann and G. C. Elliott, Manchester.
16,392 Movable Roofs or Coverings, A. J. Simpson, London.
16,393. Valves for Steam Engines, J. Pollit and E. Wigzell, London.
16,394. Game of Skill, W. and J. King, London.
16,395. Manufacture of Gas, W. F. Browne, London.
16,396. Observation Tower, M. F. Smith and H. Pettit, London.
16,397. Apparatus for Windows for Exclusion of Flies, &c., A. L. Isaacs, London.
16,398. Rock and Ore Breakers, R. D Gates, London.
16,399. Lacing Studs, F. B. Manville and A. Mathison, London.
16,400. Applying Electricity to the Human Body, W. J. Newton, H. J. Purbrook, and H. de C. Hudson, London.
16,401. Rope Driving Mechanism, J. H. W. Hoadley, London.
16,402. Shop Saws, W. W. Holmes and C. F. Quincy, London.
16,403. Utensil for Culinary Purposes, C. E. Davey, London.
16,404. Sealing Wax, S. Estcourt, London.
16,405. Protecting Shops from Burglars, W. Whiffin, London.
16,406. Appliances for Cutting Hair, J. G. Dodd, London.
16,407. Railway Brakes, T. F. Portnell, London.
16,408. Printing Telegraphs, &c., R. A. Fowden, London.
16,409. Larding Knife, T. Rudolph, London.
16,410. Photographic Cameras, J. Tascher, London.
16,411. Oil Lamps, C. Quitmann.—(*V. R. Glashütten, Germany.*)
16,412. Hoeing Machines Steering Gear, P. Tidick, London.
16,413. Trouser Braces or Suspenders, W. Varney, London.
16,414. Disinfecting or Deodorising, M. S. Sharp, London.
16,415. Clip or Holder for Neckties, C. W. Higgs, London.
16,416. Fish Oils, S. Rosenblum and F. L. Bartelt, London.
16,417. Fish Oil, S. Rosenblum and F. L. Bartelt, London.
16,418. Telephonic Apparatus, J. Cerpaux and G. de l'Escaille, London.
16,419. Kettles, R. A. Briggs, London.
16,420. Smoke Enema Apparatus, H. H. Burckhardt, London.
16,421. Umbrella Boxes or Receptacles, Holyman and Co., London.
16,422. Manufacture of Disinfectants, R. England, London.
16,423. Electric Lamps, R. J. Rae, London.
16,424. Elastic Tires, P. Amjörn, Comte de Sparre, London.
16,425. Storage Batteries. D. Young.—(*The Hess Storage Battery Company, United States.*)
16,426. Governing Apparatus for Engines, G. H. J. van Amstel, London.
16,427. Couplings for Boring Rods, R. W. Taynton, Richmond.
16,428. Decorative Show Cards, &c, A. Tuck, London.
16,429. Cutting and Moulding Machines, C. G. Fisher, London.
16,430. Pulleys, D. Levack, A. Walker, and V. Jones, London.
16,431. Head Locks for Cycles, M. D. Rucker, London.
16,432. Shovel and Spade Handles, G. Walters, London.
16,433. Plate Holder or Carrier, E. Drechsler, London.
16,434. Regulators for Engines, H. A. House, H. A. House, jun., and R. R. Symon, London.
16,435. Cycle Saddles, J. Harrington and T. Middlemore, London.
16,436. Toys, J. Empson and J. Hewitt, London.
16,437. Bonnet Pins, J. Empson and J. Hewitt, London.
16,438. Soda-water Bottle Openers, W. F. Lovell and W. H. Janes, India.

29th *August*, 1894.

16,439. Springs for Vehicles, E. J. O'Malley and C. P. J. Fitzsimon, Drumcondra.
16,440. Chain Brake for Cycles, M. Mitchell, Stafford.
16,441. Fastening Handles to Tea-pots, T. Weir, Dublin.
16,442. Orthoptics, H. Faulkner, Leeds.
16,443. Clips or Bosses for Cycles, &c., R. Mason, Birmingham.
16,444. Bearings of Shafts or Axles, B. U. Moore, Bradford.
16,445. New Hair Fastening, E. Moore, Birmingham.
16,446. Tires for Vehicles, W. Rowland and L. B. McCulloch, Crewe.
16,447. Fire-places and Flues, E. Taylor, Blackburn.
16,448. Manufacture of Insecticide Material, J. Taylor, Liverpool.
16,449. Target Mantelets, J. Taylor, Manchester.
16,450. Wax Heater, H. S. Goodman and H. J. Newman, Northampton.
16,451. Crank-pedals for Cycles, G. Pirnie, Dundee.
16.452. Shirt Collar Studs, H. F. Talbot.—(*S. Fader, British Columbia.*)
16.453. Jacquard Carpet Apparatus, S. Holdsworth, Kidderminster.
16,454. Wedge-shaped Valve, R. M. O. Tillmann, Berlin.
16,455. Apron File and Calendar, W. D. Clemitson, London.
16,456. Horse Collars, C. McCallum, Glasgow.
16,457. Ranges, Firegrates, and the like, W. Couper, Glasgow.
16,458. Opening Sash Windows, R. Frame, Glasgow.
16,459. Safety Appliances for Elevators, B. Jones, Manchester.
16,460. Stretching Carpets, A. Anderson.—(*The Singer Manufacturing Company, United States.*)
16,461. Lock and Seal for Boxes, &c., H. Smith, Leeds.
16,462. Construction of Water-closets, W. Hodgson. London.
16,463. Obtaining Motive Power from Tides, E. Davies, London.
16,464. Lids or Covers for Bottles, &c. J. Banbury, Oxon.
16,465. An Armoured Rim Sole, H. W. Barfoot, Mayfield.
16,466. Safety Apparatus for Hoists, W. Walker, London.
16,467. Riveting Machines, J. Leveque, London.
16,468. Camp Stools, W. F. Timm, London.
16,469. Gearing and Brakes for Bicycles, S. Ward, London.
16,470. Breech-loading Rifles, A. G. Dougherty and T. B. Buskirk, London.
16,471. Folding Bed and Crib, D. Froehlich, London.
16,472. Feeding Water to Steam Boilers, J. and A. Niclausse, London.
16,473. Method of Arranging Telephones, G. Ritter, London.
16,474. Polishing Sheet Metal, &c., F. W. Koffler London.
16,475. Golf Clubs, J. G. E. H. D. S. Campbell, London.
16,476. Making Wire Fabric, T. E., W. H., and A. E. Wale and F. C. Adie.—(*White Manufacturing Company, United States.*)
16,477. Combination Corkscrew, J. Elser and E. Blass, London.
16,478. Plaiting Wire Springs, B. Cockin and G. E. Stringer, London.
16,479. Postal Wrappers, J. Fletcher, London.
16,480. Sash Fasteners, J. Halse and O. Reece, London.
16,481. Boots, F. Kennell, London.
16,482. Tea-cosy, E. W. Crebbin and J. W. S. Holt, Liverpool.
16,483. Purifiers for Seed or Grain, W. H. Price, Liverpool.
16,484. Moulding or Printing Starch, D. M. Holmes, London.
16,485. Moulding Cream Fondants, D. M. Holmes, London.
16,486. Chucks, C. F. Lorch, London.

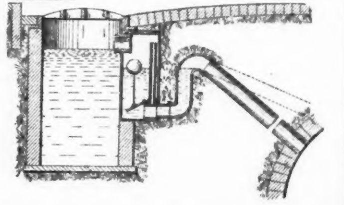
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**520,146.** Drainage System, *P. Scanlon, Chicago, Ill.—Filed March 27th*, 1893

*Claim.*—The combination with a tank, of a syphonic discharge pipe communicating therewith and having its bend or highest point at a level below the level of the top of the tank, so that the water may rise up in the tank and discharge pipe to such a height that it flows from the short to the long leg of said pipe, whereby, when the flow is sufficient, syphoning is automatically started, and a valve for closing the inlet end of said pipe when the water reaches a given level, the pipe being provided with a vent for permitting the water within in it to regain its equilibrium after the inlet end of the pipe is closed, substantially as set forth.

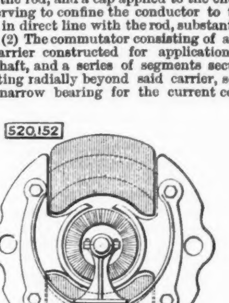
520,146



**520,152.** Dynamo-electric Machine or Electric Motor, *R. K. Welch, Philadelphia, Pa.—Filed June 24th*, 1894.

*Claim.*—(1) The combination of the commutator with the current collector, consisting of an anti-friction roller, a forked rod carrying the same, a spring for projecting the rod, and a cap applied to the end of the rod, and serving to confine the conductor to the end of the rod, in direct line with the rod, substantially as specified. (2) The commutator consisting of a central disc-like carrier constructed for application to the armature shaft, and a series of segments secured to and projecting radially beyond said carrier, so as to provide a narrow bearing for the current collector, substantially as specified. (3) The commutator consisting of a central disc-like carrier constructed for application to the armature shaft, and a series of segments secured to and projecting radially beyond said carrier, and each having a stud and binding screw for the reception of wires of the armature wind, substantially as specified. (4) The commutator consisting of a central disc, constructed for application to the armature shaft, and having a projecting flange, and segments each having a stem passing through an opening in said flange, and having a confining nut and means for insulating the said stem from the flange, substantially as specified.

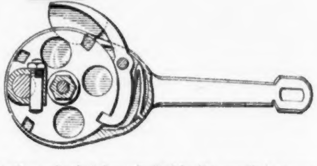
520,152



**520,157.** Variable Crank, *C. H. Davids, Brooklyn.—Filed November 1st*, 1893.

*Claim.*—(1) The combination with a velocipede crank, of a circular bearing, on the axial line of which the crank is pivoted, the said bearing being provided with a plurality of notches along its periphery a spring-actuated locking dog pivoted to the crank with its operating arm accessible to the foot of the rider, the locking dog having an engagement with the notches on the said bearing to lock the crank positively to the bearing, and means for securing the bearing excentrically to the drive shaft of a velocipede, substantially as set forth. (2) The combination with a crank provided with a recess, of a circular bearing adapted to seat within said recess, means for pivoting the crank to the bearing on the axial line of the latter, a spring-actuated dog pivoted to the crank in position to engage the bearing, the said dog having an operating arm extended to the exterior of the crank and means for securing the bearing to a shaft, substantially as set forth.

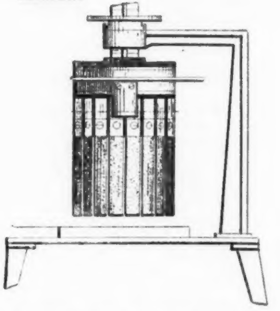
520,157



**520,300.** Method of Heating, Welding, or Working Metals Electrically, *C. L. Coffin, Detroit, Mich.—Filed October 7th*, 1893.

*Claim.*—The herein-described method of heating metal, consisting in subjecting the metal to the influence of a moving voltaic arc while simultaneously heated by radiation from incandescent electrodes in proximity to, but not in contact with the metal.

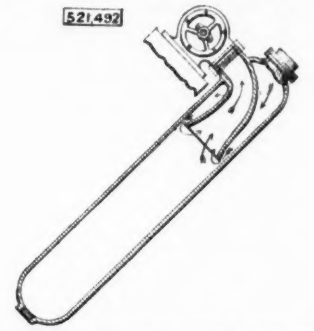
520,300



**521,492.** Steam Separator, *G. W. Aulmann and W. R. Harris, Des Moines, Iowa.—Filed February 23rd*, 1894.

*Claim.*—In a steam separator, a separator chamber having an open top adapted to be connected with a steam supply pipe and an opening in its bottom to discharge water, and a steam conductor extending outward from the top of said chamber and adapted to be connected with a valve chamber and extending downward in the separator chamber and terminating in an open bell-shaped mouth, as and for the purposes stated.

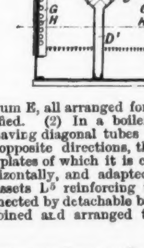
521,492



**521,532.** Steam Boiler, *D. Ahern, New York, N.Y.—Filed September 26th*, 1893.

*Claim.*—(1) In a boiler, the rectangular chamber D, and diagonal tubes $C^1C^2$ traversing it, arranged diamond-wise, as shown, in combination with the continuous water leg $D^1$ extending downward from its lower angle, the series of pipes G, headers H and connecting pipes I, serving as water legs at the sides, with the connections $D^3$ to the upper angle of the chamber and separating drum E, all arranged for joint operation as herein specified. (2) In a boiler, the rectangular chamber D, having diagonal tubes $C^1$ $C^2$ traversing it obliquely in opposite directions, the flanged lips or edges of the plates of which it is composed extended outward horizontally, and adapted to serve as supports, the gussets $L^5$ reinforcing the joint, and the panels W connected by detachable bolts to said flanged lips, all combined and arranged to serve as herein specified.

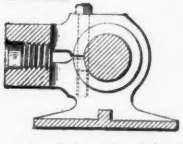
521,532



**521,695.** Device for Securing Piston-rods to Cross-heads, *E. J. Armstrong, Oswego, N. Y.—Filed Feb. 12th*, 1894.

*Claim.*—The combination, with a crosshead having an opening therethrough formed with screw threads, a bevelled mouth or seat at the end of said opening and a blank or unthreaded portion intermediate said bevelled mouth and the screw-threaded portion of the opening, of a piston rod having a screw-threaded end, and a nut having a bevelled face adapted to fit the bevelled mouth of the opening, substantially as described.

521,695



## THE DECENNIAL PROGRAMME FOR NAVAL CONSTRUCTION IN FRANCE.

As soon as the Naval Defence Act of Great Britain was passed in 1889, France, realising her inferiority as a maritime Power, and the difficult position that she must occupy in the future unless she raised herself to the level of the efforts which were being made in other countries, determined also to have a distinct programme issued for new naval construction. With this object in view, a campaign was actively opened in maritime centres, in Parliament, and amongst the people themselves. But it was not until the end of 1891 that the Admiralty Board of France set forth the programme that we give below in tabulated form, which was to last a period of ten years:—

| | | | | | |
|---|---|---|---|---|---|
| Sea-going battleships | | | | | 10 |
| Coast-defence ironclads | | | | | 1 |
| Cruisers | 1st class | Sheathed | 8 | 9 | 45 |
| | | Unsheathed | 1 | | |
| | 2nd class | Sheathed | 12 | 19 | |
| | | Unsheathed | 7 | | |
| | 3rd class | Sheathed | 12 | 17 | |
| | | Unsheathed | 5 | | |
| Torpedo depôt ships | | | | | 4 |
| Floating workshops | | | | | 2 |
| Torpedo gunboats | | | | | 5 |
| Torpedo boats, first-class | | | | | 8 |
| Gunboats | | | | | 7 |
| Total | | | | | 82 vessels |

Thus the decennial programme, passed by the Admiralty Board, provided that within ten years after the commencement of the year 1892 the naval arsenals and the trade should build the eighty-two vessels of which we have just given the detail; the work then was to be completed at the expiration of 1901.

The total cost for thirteen representative vessels out of each of the thirteen classes enumerated may be estimated at £4,768,000, giving an average of £366,769 for each ship. This average, multiplied by eighty-two, gives a total of thirty millions sterling in round numbers, or, in other words, the Admiralty Board decided upon a naval budget, as regarded new shipbuilding, amounting to thirty millions sterling extending over a period of ten years. From 1889 to the end of 1899, that is to say, for an equivalent period, England will have reached a figure representing nearly the double of this.

Once the decennial programme of 1891 was voted in Parliament, the Admiralty Board deemed it necessary to begin in good time the eighty-two ships, in order that they might be completed at the end of the year 1901. Now, for the first three years—1892, 1893, and 1894—the numbers laid down should have amounted to 29, viz., sea-going battleships, 6; first-class cruisers, sheathed, 2; unsheathed, 1; second-class cruisers, sheathed, 2; unsheathed, 4; third-class cruisers, sheathed, 4; unsheathed, 3; torpedo-depôt ships, 2; floating workshops, 1; torpedo gunboat, 1; gunboats, 3; total, 29.

Has this programme been carried out? This is the point to be determined. We will see first what provision was made for each of the years alluded to, then we will ascertain how these anticipations have been verified. Lastly we will make a total of all the new ships which have been laid down during these three years, a total that we will compare with the total as above, anticipated by the Admiralty Board. We shall not be long in seeing that the decennial programme has been more and more departed from; indeed, that it is on the point of being completely abandoned. The provision for 1895 will afford us proof of this fact.

What were the ships to be laid down in 1892? The Bouvet and Masséna, battleships; the Pothuau, first-class cruiser, unsheathed; the Descartes and Pascal, second-class cruisers, sheathed; the Linois, third-class cruiser, sheathed; the Foudre, torpedo depôt; the Cassini, torpedo-gunboat. Upon this estimate six vessels only out of eight were laid down, two were set aside, a cruiser of the first-class, sheathed, the Pothuau, and a second-class cruiser, sheathed, the Pascal. Already, so early as the first year, 1892, the programme anticipated failed in its execution; we shall see later on that this process will be accentuated more and more.

Before passing on to the Estimates for 1893, we think that it may be interesting to give the principal characteristics of these ships, which are not yet in the service.

The Bouvet, battleship, was laid down at Lorient. She will have three screws, worked by three independent sets of vertical engines. Total horse power, 14,000; speed, 17 knots with natural and 17·5 with forced draught. Dimensions: Length, 382ft. 3in.; beam, 70ft. 3in.; draught, 27ft. 7in.; displacement, 12,205 tons. For protection, an armoured belt 8in. to 16in. thick, and an armoured deck of 3½in. maximum thickness. Armament: Two guns, 11¾in. calibre, forward, and two, 10½in. calibre, aft, in closed turrets; eight quick-firing 4in. guns with shields upon the superstructure; twelve guns of 47 mm., and twenty of 37 mm.; five torpedo tubes. Cost about £1,080,000.

The Masséna, battleship, building at St. Nazaire, Les Ateliers et Chantiers de la Loire. Dimensions: Length, 368ft. 6in.; beam, 66ft. 6in.; draught, 26ft. 3in.; displacement, 11,730 tons. Speed, 17 knots with natural, and 17·5 with forced draught. Three independent sets of engines, developing a total of 12,600-horse power, and triple screws. Protection will be distributed as follows: At the water-line a steel belt from 10in. to 17¾in. thick; upon the turning portions of the great turrets, 13¾in., and upon the fixed parts 15¾in. of steel; upon the small turrets, 4in. to 5½in.; shields of steel for the minor artillery. The armoured deck, 3½in. The armament will consist of two guns, 11¾in. calibre, in revolving turrets, one forward, the other aft; two guns of 10½in. calibre in turrets on the broadsides; eight quick-firing guns of 5½in. calibre, also in turrets; eight quick-firing guns of 4in. calibre upon the superstructure, with hardened steel shields; thirty-two smaller quick-firers or machine guns of 47 mm. and 37 mm.; and five torpedo tubes. There will be twenty-four boilers upon the Lagrafel and d'Allest system. Cost, about £1,080,000.

The Descartes, second-class cruiser, sheathed, building also at St. Nazaire. Length, 315ft. 6in.; beam, 42ft. 4in.; depth, 30ft. 7in.; draught, 19ft. 9in.; displacement, 3888 tons; horse-power, 9000; speed, 18 and 19 knots. A protective deck, sloped at edges. Armament: Four 6¼in. quick-firing guns in sponson ports on the bows and quarters; ten 4in. quick-firing guns, four pointing ahead and astern, six raised upon the shelter deck and forecastle; fourteen of 47 mm.; eight of 37 mm.; and two torpedo tubes ahead. Cost, a little more than £320,000.

The Linois, third-class cruiser, building at La Seyne, Forges et Chantiers de la Méditerranée:—Length, 321ft. 6in.; beam, 34ft. 6in.; draught, 17ft. 5in.; depth, 22ft. 5in.; displacement, 2270 tons; horse-power, 6600; speed, 19 and 20 knots, with natural and forced draught respectively. A protective armoured deck of 1½in. in thickness. Armament: two quick-firing guns, 4in. calibre, forward and aft; four quick-firing guns, 4in. calibre, sponsoned out on the broadside; eight quick-firing guns of 47 mm.; four quick-firing guns of 37 mm.; four revolving guns of 37 mm., and four torpedo tubes, two ahead, two pointing laterally. An armoured hardened steel conning tower of 4in. thick for the captain. Cost about £200,000.

The Foudre, torpedo depôt ship, building at Bordeaux, Chantiers de la Gironde. Torpedo depôt ships are intended to accompany squadrons of armoured vessels, and to place at the disposal of admirals a certain number of torpedo boats, which will arrive in good condition, because they will not have made the passage by their own efforts. But this type is a subject of sharp controversy amongst French sailors; some deem that it is useless, each battleship being able to carry similar torpedo boats to those which are found upon the Foudre. Others believe that this class of ship is destined to render great service, being a valuable attribute to a squadron, as a sailing torpedo depôt and workshop. The Foudre has a length of 370ft. 6in.; beam, 51ft. 3in.; draught, 20ft. 2in.; displacement, 5970 tons; horse-power, 11,000; speed, ordinary draught, 18·5 knots; forced, 19 knots. An armoured protective deck, 2in. thick in the centre, 4in. thick on the sides. The armament comprises eight guns, quick-firing, of 4in. calibre; four of 65 mm.; four of 47 mm. and five torpedo tubes. This cruiser will carry upon the deck eight 14-ton torpedo boats, of a speed of 16·5 knots, that she can embark and disembark by means of derricks. Moreover, she will have special machinery that will enable her, during the course of a campaign, to repair torpedoes and their gear. The Foudre is a natural sequence of the Hecla and Vulcan, British torpedo vessels. The cost will be £400,000.

The Cassini, torpedo gunboat, building at Graville, near Havre, by the Forges et Chantiers de la Méditerranée. Length, 262ft. 6in.; beam, 27ft. 4in.; draught, 11ft. 6in.; depth, 17ft. 4in.; displacement, 943 tons; horse-power, 5000; maximum speed, 21 knots. The motive power will consist of two sets of vertical triple-expansion engines, making 266 revolutions per minute. The armament will comprise one quick-firing 4in. gun; three of 65 mm. and four of 37 mm., with three torpedo tubes. Cost nearly £120,000.

Let us pass now to the year 1893, and see what was to be laid down for that year. The d'Entrecasteaux and Jeanne d'Arc, first-class cruisers, sheathed; the Pascal, second-class cruiser, sheathed; the Duchayla, d'Assas, and Catinat, second-class cruisers, unsheathed; the Galilée, third-class cruiser, unsheathed; Casabianca, torpedo gunboat; Surprise gunboat. Out of this estimate of nine vessels, seven only were laid down; two were set aside, the Jeanne d'Arc and the Catinat. On the other hand, the Pothuau was, in addition to the estimate, reinstated from the estimate for 1892 and laid down, making eight in all. Let us look at the characteristics of these eight vessels laid down in 1893.

The d'Entrecasteaux, sheathed cruiser of the first class, intended for distant stations, building at La Seyne:—Length, 384ft.; beam, 58½ft.; draught, 23ft. 6in.; water-line area, loaded, 1534 square metres; displacement, 8144 tons; horse-power, 14,000; estimated speed, 19 knots, with moderate forced draught, and burning 130 kilos. of fuel for each square metre of grate surface. The steam will be supplied by five cylindrical boilers of return draught pattern, placed, four in front of the engines, and the fifth behind, between the screw shafts, a disposition which will admit of bringing the engines near the centre of the ship, and of giving them more room. The boilers will be tested to 10 kilogs. Protection will be afforded by an armoured deck with sloping edges, 4in. thick, plating included, at the sides, and by another horizontal deck ⅞in. thick above; the space between these two decks will form an immense cellular caisson, which will contain reserve fuel and stores. The hull will be entirely devoted to the engines, the boilers, and the magazines, which will be very numerous, each gun having its own separate ammunition trunk. All the auxiliary apparatus, steering engines, electric engines for lighting and for the distribution of power to the helm, and for the working of the guns, such as the ammunition hoists, turret gear, &c., will be under the shelter of the armoured deck. All will be actuated by electricity. The armament will include two 9½in. guns of 40 calibres, in closed balanced turrets fore and aft, protected by 10in. of steel, and trained by electricity. Twelve quick-firing 5½in. guns will be distributed as follows:—Four upon the spar deck, bearing ahead and astern, placed in the centre of the ship, and protected by 2¾in. shields of hardened steel and by the bulwarks; eight in a redoubt upon the upper battery, protected as the others, and all firing axially, thanks to their disposal *en échelon*. Each of the 5½in. guns will have its magazine and its rack for projectiles. Twelve quick-firing guns of 47 mm., and four of 37 mm., will be distributed upon the superstructure and in the tops; these will have regular platforms. Two torpedo tubes below and five above the water-line. There will be two military masts, with interior staircases. The d'Entrecasteaux will be very solidly constructed. The weight of the hull amounts to 2989 tons, that is to say, 36 per cent of the displacement; the armour will weigh 1670 tons, the armament 482 tons, the motive apparatus 1395 tons, and at normal draught the ship will carry 650 tons of coal—but with the reserve supply, this quantity will increase to about 1000 tons, which will give a good radius of action. The d'Entrecasteaux will be the largest of the French cruisers. Like all modern vessels, she will be complicated. However, it may be said that the autonomy of and the protection afforded to each of the guns will be complete, and that great care has been taken to localise possible damages caused by the fire of the enemy. Besides the armoured conning-tower, several protected positions have been arranged for the captain. The ship will cost about £680,000.

The Pothuau, first-class cruiser, building at Havre by the Forges et Chantier de la Méditerranée, is a Latouche-Tréville, enlarged and more powerfully armed. She will cost a little more than £440,000.

The Pascal, second-class cruiser, sheathed, building in the arsenal at Toulon. Similar to the Descartes, described above. Cost, about £320,000.

The d'Assas, second-class cruiser, building at St. Nazaire. Length, 325¼ft.; beam, 44ft. 11in.; draught, 19ft.; depth, 29ft. 9in.; displacement, 3952 tons. Protective deck on the flat, 1¼in.; on the sloping sides, 3⅛in. Two vertical triple-expansion engines, developing a normal horse-power of 6000; maximum horse-power, 9500. Steam supplied by twenty d'Allest boilers, tested to 20 kilogrammes to the centimetre; speed, 19 knots. Armament: Six 6¼in. quick-firing guns, four 4in., twelve of 47 mm., sixteen revolving guns of 37 mm., and six torpedo tubes. Cost, £300,000.

The Duchayla, second-class cruiser, building at Cherbourg. Similar to the d'Assas, just described.

The Galilée, third-class cruiser, building at the arsenal, Rochefort. Length, 321½ft.; beam, 35ft. 1in.; draught, 14ft. 7in.; depth, 23ft. 2in.; displacement, 2317 tons; horse-power, 6500; speed, 19 and 20 knots with natural and forced draught respectively. A protective armoured deck with sloping edges. Armament similar to that of the Linois, already described; a conning-tower for the captain, 4in. thick, of hardened steel. Cost, £200,000.

The Casabianca, torpedo gunboat, building at Bordeaux, Chantiers de la Gironde. Length, 262ft. 6in.; beam, 27ft. 4in.; draught, 10ft. 3in.; displacement, 943 tons. The strength of the hull is reinforced, and it is of hardened steel in the vicinity of the engines and boilers. Two vertical four-cylindered engines will give her a speed of 21½ knots, with the maximum power of 5000 horses. The boilers, upon the d'Allest system, will be tested to 15 kilos. to the centimetre. They will be arranged in four groups, each with two furnaces. Armament: One quick-firing gun of 4in. calibre, three of 65 mm., five of 47 mm., four of 37 mm. Cost, £100,000. She is a sister-ship to the Cassini.

The Surprise, gunboat, designed by M. Normand, who is building her at Havre. Length, 183ft. 9in.; beam, 24ft. 7in.; draught, mean, 10ft. 2in.; depth, 14ft.; displacement, 626 tons. The Surprise will be of steel, sheathed, and will have one propeller. A vertical engine and four cylinders will develope 650 and 850-horse power with natural and forced draught respectively; maximum speed, 13 knots. Boilers tested to 11·25 kilos. to the centimetre. Armament: Two quick-firing guns of 4in. calibre, four of 65 mm., four of 47 mm. This gunboat will have three masts—two masts barque-rigged, the foremast square-rigged. The total sail surface will be 344·93 square metres. Cost, £48,000.

Let us now pass along to 1894, and see what ships were estimated to be laid down this year:—The Henry IV., Charlemagne, and Saint Louis, battleships; $E^4$, $E^5$, $E^6$, second-class sheathed cruisers; $G^3$ and Cassard, second-class unsheathed cruisers; Lavoisier, third-class unsheathed cruiser.

Out of these nine estimated units, *four only* have been laid down—the Charlemagne, the Saint Louis, the Cassard, and the Lavoisier. All the other units have been relegated to 1898, or even to a more distant date; but it is only fair to say that two units not estimated for in 1894 have been laid down this year—the Jeanne d'Arc and Catinat, reinstated from 1893. It is thus shown that, in 1894, six ships will be laid down instead of nine.

The Charlemagne, battleship, building at Brest Arsenal. Length, 385ft.; beam, 66ft. 7in.; draught, 25ft. 10in.; displacement, 11,232 tons. The height of the freeboard guarantees her being a good sea boat. The subdivision of the hull has been specially studied, with a view of reducing as much as possible the danger caused by the inrush of water upon the main deck and into the compartments alongside. In order to minimise the effects of a blow from a ram, or of the explosion of a torpedo, the designer has multiplied the compartments of the hull, especially alongside. With a view of increasing the protection against projectiles striking the armour on the main deck, he has adopted two armoured decks—one, 2½in. thick, situated, as in all other ironclads, at the level of the upper edge of the armoured belt; the other, 1½in. thick, situated at the level of the lower edge. Below this second deck will be placed all the vitals of the ship, engines, boilers, apparatus for training the turrets, magazines, &c. The space between the two decks is, properly speaking, an enormous cofferdam. It is extensively subdivided, so as to stop the inrush of water. The armoured belt which surrounds the ship is 6ft. 6¾in. in width; its upper edge rises to 19½in. above the water-line. In the middle of the ship the thickness of this belt is 15¾in., over a depth of 2ft. 3½in., measuring from the upper edge. The belt decreases from this downwards to the lower edge, where it is only 10in. thick. Armour, 3in. thick, which goes completely round the ship, secures the foot of the upper works from the destructive effect of lighter ordnance. Behind the light armour runs along a cofferdam, one metre in height, which rests upon the main deck, and goes round the ship. The divisions, in sheet steel, of this feature complete the subdivision of the space situated above the main deck. The getting rid of the water which reaches the main deck, by possible damages of the outer skin, is effected by means of large pipes, which expel the water at once, without the necessity of discharging it at first into the hold, or into a drain. A battery, composed of eight quick-firing guns of 5½in. calibre, is placed under the shelter deck, which extends to the forecastle. It is protected by exterior steel armour, 3in. thick, including the plating, and by a traverse similarly armoured forward, which descends to the main deck. In order to provide that a projectile bursting in the battery shall not disable all the guns at once, each of them is enclosed in a drum of plate steel, which isolates it from its neighbours. The superstructure is less developed than upon the earlier ironclads. The conning tower, placed before the foremast, is armoured with 4in. steel. Beside this conning tower there are two other armoured cylinders from which the captain can transmit his orders to the engines and to the helm. These three protected posts are connected with another post situated upon the lower deck, at the foot of the armoured trunk which connects the principal conning tower with the interior of the ship, and from thence orders can radiate to the boiler-rooms, engine-rooms, turrets, &c. The military masts have double staircases inside; besides two tops at their highest part, they carry a shield at a certain height above the bridge. Anchors will be supplied upon the Manel system.

The motive power will embrace three triple-expansion engines, with four cylinders to each, of which two can be detached. Each of these engines will work a screw. One of the screw-shaft beds will be placed in the longitudinal axis of the ship, the two others will be alongside, and the screws will be distributed over a frontage of very considerable extent. Each engine will be placed in a water-tight compartment. They will communicate with one another, and with the boiler-room compartments, by means of water-tight doors situated upon the upper floors. Twenty boilers upon the Belleville system will supply steam. The engines are calculated to develope 14,000-horse power with forced draught. Estimated maximum speed, 18 knots; with natural draught the speed should be 17 knots. The supply of coal, sufficing to steam 4000 knots at a speed of 10 knots, will be about 600 tons; but the bunkers are calculated to receive a much more considerable quantity—about 1100 tons.

The armament will comprise four guns of 11¾in. calibre, of the 1891 model, mounted in pairs in two closed turrets placed at the ends of the ship; ten 5½in. quick-firing guns, eight in the battery before alluded to, two upon the shelter deck; six 4in. quick-firing guns upon the shelter deck; sixteen of 47 mm.; eighteen of 37 mm.; four submarine torpedo tubes, two ahead on the bows and two astern, bearing on the quarters; and six torpedo-tubes above the water-line. The forward turret has a command of 27ft. 10in., and the aft turret a command of 21ft. 4in. We have already indicated the means adopted for protecting the guns mounted in the secondary battery. Upon the shelter deck, the 5½in. guns will have a revolving shield, but those of 4in. calibre will be without any protection. The disposition of the ammunition magazines will be especially convenient. All the magazines will be found directly beneath the guns which they supply. Speaking generally, all applications of power will be effected by means of apparatus moved by steam, hydraulic force, or electricity. The ship will be completely lighted by electricity, and will have six projectors.

The Saint Louis, battleship, building at the Arsenal at Lorient, will have similar characteristics to those which we have noted in the Charlemagne. Each of them will cost about £1,080,000.

The Jean d'Arc, first-class cruiser, sheathed, estimated to be laid down in the year 1893, was provisionally laid aside. The anticipated expenditure on her for 1894 will be £6440.

The Catinat, second-class cruiser, will be sheathed with wood and coppered, which shows that she is intended for distant stations. Building at Graville, near Havre, by the Forges et Chantiers de la Méditerranée. Length, 328ft. 9in.; beam, 41ft. 4in.; draught, 19ft. 8in.; depth, 30ft. 6in.; displacement, 3998 tons. Protection, an armoured deck of 1⅛in. on the flat, of 1⅝in. upon the glacis. This deck will be laid upon plating ⅜in. thick. A cellular band will run along above the armoured deck, over which will be a splinter deck. Horse-power of engines 7000 with natural draught, 9000 with forced. Maximum speed 19 knots. The boilers will be upon the Belleville system. Armament, four 6¼in. quick-firing guns; ten 4in.; fourteen 47 mm.; four 37 mm., and six torpedo tubes of 13¾in. calibre. The 6¼in. guns will be in sponsons upon the deck; four 4in. guns will be under the forecastle, and two upon it; four distributed upon and under the poop. A portion of the 47 mm. guns will be in the lower tops, the 37 mm. guns in the upper tops. She will have six electric projectors, two military masts, and two tops on each. The conning tower for the captain will be of 4in. steel armour. The cost will be a little over £320,000. The Cassard, second-class cruiser, unsheathed, building at Cherbourg Arsenal, will be similar to the Duchayla and the d'Assas, which we have already described. The Lavoisier, third-class cruiser, not sheathed, building at Rochefort, similar to the Galilée.

We have seen at the outset of this brief survey that the number of ships laid down in 1892, 1893, and 1894, should amount to 29 units; in reality they only compute to 20, of which the following is the detail:—

| | | | 1892. | 1893. | 1894. | Total. |
|---|---|---|---|---|---|---|
| Battleships | | | 2 | — | 2 | 4 |
| Cruisers | 1st class | sheathed | — | 1 | 1 | 2 |
| | | unsheathed | — | 1 | — | 1 |
| | 2nd class | sheathed | 1 | 1 | 1 | 3 |
| | | unsheathed | — | 2 | 1 | 3 |
| | 3rd class, unsheathed | | 1 | 1 | 1 | 3 |
| Torpedo depôt ship | | | 1 | — | — | 1 |
| Torpedo gunboats | | | 1 | 1 | — | 2 |
| Gunboats | | | — | 1 | — | 1 |
| Total | | | 6 | 8 | 6 | 20 |

There will only have been laid down, therefore, during the three years, four battleships instead of six; three second-class cruisers unsheathed instead of four; one torpedo depôt ship instead of two, and one gunboat instead of three. The programme for first-class cruisers will, however, have been accomplished, and it will be exceeded by one second-class cruiser sheathed, and one torpedo gunboat. But nothing will have been done for the four sheathed third-class cruisers, or for the two floating workshops.

To sum up, we repeat that, instead of twenty-nine units, we shall only find at the expiration of the year 1894 twenty units upon the stocks—nine will be wanting at the roll-call. For 1895, the scheme presented to the Chamber of Deputies has only anticipated the laying down of two ships—a battleship, $A^7$, and a second-class cruiser, $E^4$. As for the Henry IV., the sheathed second-class cruisers $E^5$, $E^6$, and a second-class cruiser, unsheathed, $C^2$, they are relegated to a date more or less distant.

We were right, then, in saying, at the commencement of this paper, that the decennial programme for naval construction in France had not been verified. This is what we wished to prove.

## THE DECADENCE OF SHIPBUILDING ON THE MERSEY.

The present condition of Mersey shipbuilding affords distinct evidence that the industry, so far as some of the yards are concerned, is in a moribund state. Time-honoured firms, which have turned out their 16,000 or 17,000 tons in a year, are now doing absolutely nothing. Their yards are completely idle; nor is there at present any prospect of improvement. The brisker demand for new vessels which marked the closing months of 1893 failed to influence the Mersey outlook. It is regrettable that such should be the case, for Liverpool's shipbuilding associations are quite historical. During the latter half of last century, Liverpool builders were in great demand as constructors of war vessels. In 1758 the Venus frigate was launched. The slip on which she was built has long been absorbed by the Mersey Dock estate, a similar fate having overtaken many of the older shipbuilding yards. In 1777 his Majesty's ship Harpy, twenty guns, was launched, and she was followed in the next year by the Penelope, twenty-eight guns. In 1779 the Ulysses, forty-four guns, was launched; while during the next three years no fewer than twelve vessels, carrying in all 380 guns, were built to the order of the Government. It is difficult to convey any idea of the activity among Liverpool shipbuilders in those warlike days. The Mersey port in 1779 boasted a fleet of 120 privateers, many of them expressly built for belligerent purposes. Repairs and refits were frequently necessary, as well to them as merchant vessels; and there was besides the steady demand for Liverpool-built merchantmen.

Liverpool's early shipbuilders established, and their successors have maintained, a well-deserved reputation for good work. In the strength of their craft they must have had every confidence, for in 1763 one firm of builders launched a vessel, the snow Happy, which modern phraseology would dub a small barque, completely rigged and laden. The launching over, the vessel proceeded at once on a voyage to Africa. In 1773, the Kent, of 1100 tons, was launched, she being the largest vessel built in the North of England up to that date. Two years later a Greenlandman was first built on the banks of the Mersey. She was named the William, and a staunch craft she proved herself, for after close upon half a century of hard service she was used as a floating chapel, and was finally broken up in 1850.

There is no need to follow the progress of Liverpool's shipbuilding through the long roll of merchant vessels, Indiamen, and war vessels. The Mersey port had a very considerable share of the trade in those days, and among the more interesting vessels which the Mersey yards have constructed during more recent years may be mentioned the steamship United States (1840), afterwards the Oriental, the Hindostan (1842), a steamer of 2017 tons, built for the Peninsular and Oriental Company, the steam frigate, Birkenhead (1845). Coming to more modern history still, we have the Alabama, the ill-fated Captain, the Agincourt, and foremost among a fleet of steam and sail, the flyer Columbia. Nor must the last famous production of Messrs. Laird's yards, the Royal Oak, be omitted.

It seems hard that a river which has such an illustrious record should fail to be patronised by those who have orders to place.

So far as the river itself is concerned, there could not be a better for shipbuilding purposes. It is not the river but its position which is partly responsible for the decadence of this industry. The Thames at one time shared with the Mersey the foremost position among shipbuilding rivers. The decline of each seems to be proceeding on somewhat parallel lines. Both turn out a certain amount of Government work. Apart from this, the Thames produces little but barges, and it is quite possible, in view of Manchester Ship Canal potentialities, that the Lancashire estuary may develope a building business in a similar direction. During the last seven years the output of tonnage on the Mersey has been as under:—

| Year. | Mersey Tonnage. | Total British Tonnage. |
|---|---|---|
| 1887 | 10,664 | 585,430 |
| 1888 | 22,538 | 912,299 |
| 1889 | 35,773 | 1,317,033 |
| 1890 | 30,577 | 1,291,090 |
| 1891 | 23,736 | 1,293,560 |
| 1892 | 39,330 | 1,280,989 |
| 1893 | 9,071 | 917,166 |

The drop from close upon 40,000 tons to a little over 9000 is a very serious matter; but in the matter of work really done, the falling-off is not so great as it appears at first sight. In 1892 Messrs Laird launched the twin-screw gunboats Onyx and Renard, and floated from their constructing-dock the first-class battleship Royal Oak. The total tonnage of these vessels is over 15,000. During 1893 a great deal of work was done to these craft before they were finally completed and handed over to the Admiralty. In addition to this, Messrs. Laird contributed about half the tonnage turned out from Mersey yards, their principal item being the Vanderbilt yacht Valiant, of 1828 tons, and engines of 4500 indicated-horse power. Of the remaining tonnage, Messrs. Royden were responsible for a steel sailer of 2846 tons, and Messrs. Potter for four vessels with an aggregate tonnage of 548. Messrs. Jones launched the St. Brieuc, a steamer of 400 tons; and the remaining tonnage is composed of wood and steel barges built by Messrs. Cochrane and Messrs. Gilchrist.

The outlook for 1894 is bad, decidedly worse, in fact, than it was during 1893. The old-established yards of Messrs. Roydon and Messrs. Potter are doing nothing, although, together, they are capable of turning out 30,000 tons in a year. Messrs. Evans had in February a sailing vessel of 2500 tons almost ready for launching, but up to the present little in the shape of orders has turned up to take its place. No prospect of improvement is the verdict from the Liverpool yards; and where a few years ago business and activity reigned, one sees deserted yards and closed gates labelled with the significant notice, "To Let."

The causes of this condition of things are after all not far to seek. First and foremost is the fact that the Mersey is removed from the coal and iron centres, more especially the latter. When every ton of iron or steel has to bear an extra impost of ten or twelve, or even more, shillings for carriage, plus a further charge of one shilling and sixpence per ton cartage from the nearest railway depôt, it will be readily admitted that the Liverpool shipbuilder labours under an enormous disadvantage. In these days of keen competition it cannot be expected that any industry can flourish under such drawbacks. The Liverpool builders, however, still receive inquiries, but as one of them remarked to the writer, "They only aggravate us; we cannot touch them." Shipowners who in the past have derived every satisfaction from their Mersey-built vessels confess that it is with a certain amount of pain they place their orders elsewhere. The work, they admit, is excellent; but they cannot, in a depressed state of trade, shut their eyes to the fact that other yards are considerably cheaper.

There is another factor that operates against the success of the Liverpool yards. The trading tendency of the present day is opposed to the Mersey shipbuilders. The private yard, so potent in the past, is clearly doomed. The big companies in ship construction, as in other businesses, must sooner or later swamp private enterprise.

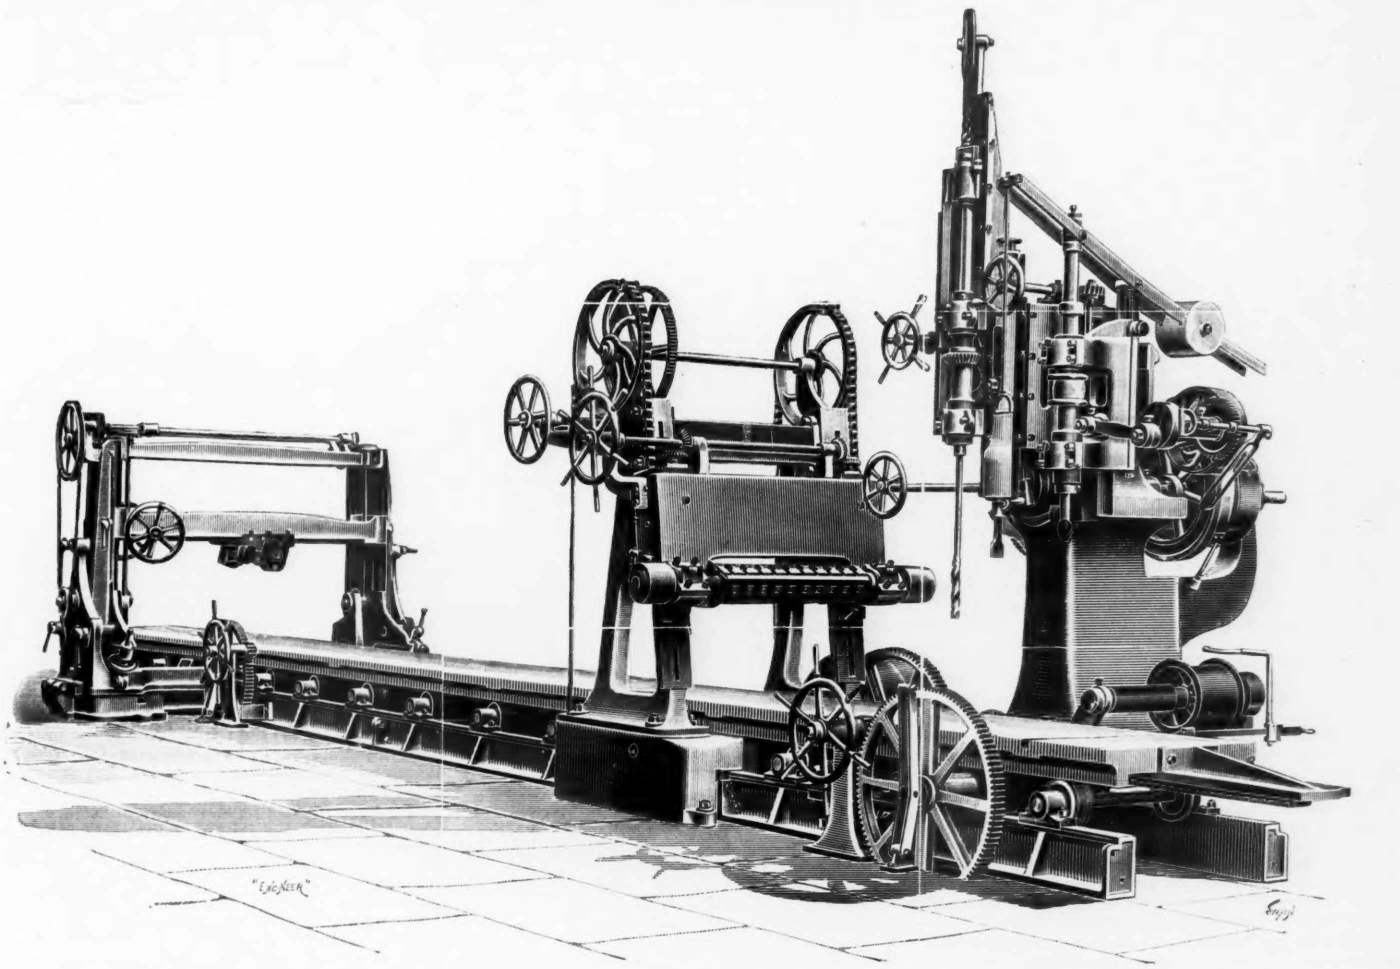
The two causes mentioned above would militate against the success of similarly circumstanced yards anywhere. But the Liverpool yards—that is those on the Lancashire side of the Mersey—have a still further adverse force to battle. They are under and form part of the Mersey Dock Estate, and consequently fall under the jurisdiction of the Mersey Docks and Harbour Board. The policy which these managers of the Port of Liverpool adopt towards shipbuilders is one of repression, or at best mere toleration. To begin with, the rents charged for shipbuilding sites are extremely high. Few builders can afford at the present day to pay a rental of 1s. 6d. per yard, with rates and taxes in addition. Such a burden as this may not be seriously felt in good times when work is brisk, but when the rent has practically to fall upon one or two vessels the margin of profit must be a very narrow one indeed. The Dock Board again will not lease their yards. Those to whom they are let are six-monthly tenants, and though it cannot be contended that occupiers of yards might be turned out of their holdings without due consideration to their contract obligations, &c., yet it is a well-known fact that sooner or later the yards will be wanted for dock sites. At present the Liverpool yards of Messrs. Jones, Evans, Potter and Royden have docks on all sides of them except the westward, on which lies their river frontage. The Dock Board, too, make no efforts to cater for the shipbuilding industry. From their point of view, the revenue from the yards is a mere bagatelle. For the year ending July, 1893, it stood at £3953 5s. 3d., a small item among aggregate rents of close upon £120,000, and total receipts of £1,330,336. According to the Dock Board, too, these rents must be considered irreducible, so that taken altogether, the Liverpool shipbuilder has a hard time of it. He complains, too, of the cost of unskilled labour, which is doubtless owing to the constant employment that offers at the docks to the better classes of unskilled labourers.

There is at Liverpool, too, a lack of such facilities as are necessary for shipbuilders in these days of quick despatch. The masting of vessels is usually performed in a dock close to the four yards mentioned above. Here the Dock Board have provided a crane capable of lifting twenty tons, but *the motive power is hand*. To put the lower sticks into an average sailer is thus made an operation both tedious and costly, the crane generally employing twenty-two men at least a couple of days during the process.

Years ago, in describing the industries of Liverpool, it used to be shipbuilding and ship repairing. Now this is reversed, it is ship repairing first, and shipbuilding afterwards. This is not very gratifying to those who are interested in this long-established Mersey industry, and it is still less pleasing to learn that the progress of degeneration is not yet complete, that the repairing business labours under such disabilities as frequently drive owners to send their vessels to other ports. Vessels entering Liverpool docks for repairs are charged dues just as if they came to discharge or load cargo. The graving dock rates of course cannot be grumbled at, but owners can hardly be expected to saddle themselves with heavy dues by sending their vessel to Liverpool to be repaired. If

# DOCK GATE MAKING MACHINERY FOR THE MERSEY DOCKS AND HARBOUR BOARD

MESSRS THOMAS ROBINSON AND CO., ROCHDALE, ENGINEERS



she has brought cargo to the port it is of course another matter. This grievance of ship repairers—and the repairers are the builders as well—is felt to be a serious one. The opening of the Ship Canal might, under other conditions, have brought business to Liverpool; but as things are at present, the Liverpool builders and repairers cannot compete for the repairs to vessels injured in the Manchester waterway. It may be thought that the question of ship repairing is hardly relevant to the discussion of Mersey shipbuilding, but in a great port like Liverpool the two industries go hand-in-hand.

That Liverpool's shipbuilding is doomed there can be no doubt. The very fact that of the 725,532 tons built for British firms during 1893, something like 110,000 tons was for Liverpool owners, is eloquent testimony as to the lower rates of other builders. At the beginning of the present year, when quotations for new tonnage were on the rise, it was hoped that past history would repeat itself, and that Liverpool builders would benefit. Though the outlook was thus a little brighter, it must be admitted that material betterment is as far off as ever. Possibly the Dock Board, now that the opposition to the port has led them to undertake the redress of grievances, may be induced to deal a little more tenderly with the shipbuilding fraternity, and this may doubtless tend to postpone the evil day when Liverpool will cease to be counted among the shipbuilding centres.

## IMPROVED WOOD-WORKING MACHINE FOR THE MANUFACTURE OF DOCK GATES.

Those of the members of the Institution of Mechanical Engineers who paid a visit to the works of Messrs. Thomas Robinson and Son, Rochdale, during the recent summer meeting, had an opportunity of inspecting a new machine, or rather combination of machines, which had just been completed by this firm for the Mersey Docks and Harbour Board, and which is intended for preparing the timber required in the construction of the ten pairs of gates which will be necessitated by the extensive alterations and improvements at the north end of the Liverpool Docks. This machine, which we are now enabled to illustrate, is intended to perform the operations of planing, shaping, tusking, tenoning, morticing, and boring baulks of greenheart timber up to 60ft. long by 3ft. square, without the necessity of moving them from one machine to another, and with this object in view, one long travelling table serves for the whole of the operations.

The operations of planing and shaping the baulks of timber are performed by means of revolving cutters attached to a horizontal cutter block driven at high speed by two belts. It is mounted on the slide plate of a vertical headstock, and spans the travelling bed which carries the timber. The cutter block slide plate is in two parts; the front portion which carries the cutter block is made to slide on the back portion so that the cutter block can be raised or lowered through a short distance by means of screws for the purpose of adjusting the depth of cut. The whole slide plate is capable of moving up and down freely on the face of the headstock, its weight being counterbalanced by means of weights suspended by chains below the floor. A friction roller is attached to the slide plate, which, when allowed to rest on a curved template fixed on the travelling table, will cause the cutter block to rise and fall with the curve, and so shape the timber on which it is operating to the form of the template. This arrangement is for the purpose of shaping one side of the timbers which form the ribs of the gates to the required curvilinear form. When required to plane a level surface the slide plate is cramped fast to the headstock at the required height above the table, and the depth of cut is adjusted by raising and lowering the cutter block by means of the screws and slide on the back slide plate provided for the purpose. For the operation of morticing and boring there are provided two machines, one fixed on each side of the travelling table, so that one cuts the mortices and bores the holes along one edge of the timber, and the second performs a similar operation along the other edge. This arrangement permits the work to be done where required on the timbers without having to traverse the tools completely across the timbers, and so cause them to be unduly overhung from the standard on which they are carried. The mortice holes are first cut out to the required depth by means of a revolving routing tool, and the ends are squared by means of a reciprocating chisel. Holes to a depth of 30in. are bored by means of a spindle driven by bevel gearing, and attached to the same headstock as the morticing tools. The headstock which carries these tools is arranged to slide in a lateral direction across the bed, so as to enable the work to be done on different portions of the timber without its being necessary to move the latter in any but a forward direction.

The operation of tusking consists in cutting a series of bevelled seatings across the face of the timbers which form the upright posts of the gates. These seatings form beds on which rest the shoulders of the tenoned ends of the transverse ribs. The appliance for tusking has been made from the designs of Mr. Thomas Owen, one of the employés of the Mersey Dock Estate. It consists of a pair of cast iron standards between which the table carrying the timber travels. A sliding carriage, on which is mounted a horizontal cutter spindle with a cutter block on each end, is carried on these standards, and is raised or lowered or traversed in a lateral direction across the timber by means of screws turned by hand-wheels. The standards are supported on trunnions, on which they can be canted forward or backward to any desired angle, and the trunnions are mounted on a swivelling bed, which can be turned on a centre pin so that the cutter blocks may operate on the timber at different angles. By this arrangement of canting and swivelling the standards on which the cutter blocks are carried, the machine is enabled to cut the tuskings and tenon the ends of the timbers at any required angle. It should be stated that Mr. A. G. Lyster, M. Inst. C.E., is the engineer for the above-mentioned undertaking.

## RAILWAYS IN INDO-CHINA.

So rapid has been the commercial development of the French possessions in Indo-China during the past two or three years, that the authorities have found it necessary to propose a vast scheme of railway construction, of which the details have already been thoroughly worked out. Up to the present moment Tonkin has only possessed a single line, of comparatively small importance, connecting Hanoi with Lang-Son, and though it was laid down for strategical reasons, it has yet proved to be of great service in directing a large current of trade to the Red River. It is with a view of opening up new territories that the Governor-General, M. de Lanessan, has made concessions for the laying down of lines to French engineers, and these concessions are now only awaiting the sanction of the Chamber of Deputies. It is thought to be practically certain that the Chamber will unanimously favour the project, as it will entail no expense whatever on the mother country, and all the charges incidental to this enterprise will be borne by the colony, whose budget shows a large excess of receipts over expenditure. One line of 700 kiloms. from Hanoi to Hué and Tourane has been conceded to a syndicate represented by MM. Vézin and Raveau, of the Compagnie de Fives-Lille. The cutting and banking for this line have already been partly carried out, and the rest will be done by the Annamite villages through which the railway will pass. Other lines conceded to M. Soupe and Raveau, of the Fives-Lille and the Cie. des Messageries fluviales de Cochinchine, are one from Saigon to Touraine and Hué, a distance of 800 kiloms., and a steam tramway intended to connect the capital of Tonkin with the new railway which they are themselves constructing from Phu-Lang-Thuong to Lang-Son. This railway is to be further extended as far as Binh-hi. Concessions have also been made to M. Portal, the director of the Kébao mines, who is acting for the Cie. Commerciale et Industrielle du Tonkin, and for a syndicate of Parisian capitalists. These concessions include a line from Kébao to Laokay, a distance of 450 kiloms.; from Kébao to Lang-Son, from Haiphong to Sontay, from Hanoi to Chai-Ngngen, and from Kébao to Moncay. The length of lines thus conceded to M. Portal is 1100 kiloms., all of which is to be constructed in Tonkin. The estimated cost of the entire system is £8,400,000. In Indo-China, as elsewhere, the 0·60 metre gauge has entirely gone out of favour, and all the new lines will be constructed with a metre gauge, which thus becomes the standard gauge in the colony. It is urged that while the metre gauge only entails a very little extra expenditure, the line is much more flexible than if constructed with the narrower gauge, and has a capacity not much inferior to that of the larger lines. This has been proved—in Tonkin, at least—by the working of the lines at the Kébao and Hongay collieries. It has been decided that all the material required in the construction of these 3000 kiloms. of railway shall be supplied from France, and that the locomotives shall only consume fuel mined in Tonkin. Besides this work, the Kébao Colliery Company is engaged in the construction of a port at the termini of the lines conceded to the Cie. Commerciale et Industrielle du Tonkin. This port will be in a very sheltered position at Tien-Yen, and will allow of vessels drawing eight metres of water entering at all tides. Entrance to the port will be further facilitated by the erection of three lighthouses, and the whole undertaking will cost something like half-a-million sterling. It is expected that this port will become the depôt for supplying the whole of the Eastern markets with the coal mined in Tonkin, and it is further hoped that this great industrial movement will result in the establishment of manufactories in the different mining centres. At present it is impossible to develope the industrial resources of Tonkin to anything like their full extent, owing to the disinclination of French capitalists to put their money in colonial enterprises, and it was found necessary to work the coal mines in that country with capital belonging to British merchants in Hong Kong, who are thus certain to be among the first to benefit from this creation of a railway system.

## FRENCH MACHINERY AT ANTWERP EXHIBITION.

(*From our Special Commissioner.*)

IN the main building of the Exhibition French exhibits occupy an important place; in fact, there are some branches of industry in which France is better represented than even Belgium. But this is not the case in the Machinery Hall, where the French display is even smaller than the English.

In these days of international industrial enterprises, it is not always easy to divide exhibits according to their nationality. Last week, under the head of Belgian Machinery, I spoke of an exhibit which would have equal right to be called German, and the machine tools shown by Le Progrès Industriel, of Paris and Brussels, are even more cosmopolitan in their character, as this company, which manufactures in France as well as in Belgium, exhibits chiefly examples of "Pittler's Universal Lathe," and tools which are practically adaptations of it. This lathe is the invention of Herr W. v. Pittler, of Leipzig, and of High Holborn, so that it might equally well have been classed with German mechanical inventions. It has recently undergone several modifications in minor details, and the subjoined illustration will show its most recent arrangement. It will be seen that the lathe bed is in the form of a trapeze, or truncated triangle in section. On this bed, and bearing on the three upper sides, is the saddle, which is circular, and upon it the tool holder revolves. This tool holder is split at one side, and can be tightened up by a screw, so that it can either revolve freely round the saddle, or can by tightening the set screw, be securely fixed in any position. The leading screw is fitted underneath inside the lathe bed, which it traverses from end to end, so that by it the saddle, and consequently the tool holder, can be moved backwards and forwards, either by hand from the back end, or automatically, by means of small change wheels in the head. In some of these lathes, instead of a single tool there is a capstan bearing a set of tools. In others, a separate apparatus is put into the tool holder, with automatic milling cutters; these are driven from a small side wheel on the lathe, which turns a rod with a universal joint at each end. An excentric on the continuation of this rod moves the wheel to be cut, up and down; a lever on the side of the excentric turning a disc, according to the distance set. Another arrangement has a pulley at the end of the lathe, which moves a revolving cutter forward; this is used for turning spirals. Again, another modification converts this tool into a sort of copying lathe; a plate, with a slot in it is placed in the machine, and this guides the tool-holder according to the shape of the article required. One of the lathes shown is especially intended for worm wheels, another is an automatic ball-turner.

Besides lathes, the exhibitors show several varieties of milling machines. One of these can either be arranged for horizontal or vertical milling. When the vertical milling head is used, it can be turned 45 deg.; and when required it can quickly be removed, and another head with horizontal motion put in. A milling machine designed especially for making gimblets, augers, &c., has a very ingenious arrangement. It is driven by a worm, and the worm wheel is set excentrically, so that the spiral should gradually flatten.

In the illustrations, Fig. 1 is a section of the gearing of a screw-cutting lathe, through the worm-wheel shaft, at the back of the head-stock, the shaft *r* being made to pivot, so that the worm-wheel *f*, which may vary in diameter, can always be brought close up to the worm, Fig. 2 is a section through lathe bed, saddle, and tool-holder. In this, *n* is the lathe bed, *l* the circular piece which slides on it, and *a b* the tool-holder.

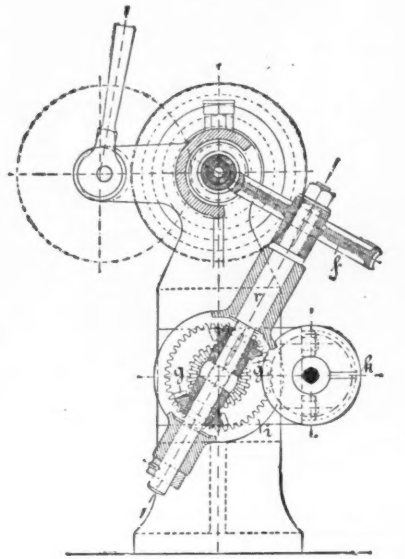
Those who are desirous of comparing the leading types of water-tube boilers have a good opportunity of doing so at Antwerp. The Babcock and Wilcox, De Naeyer, and Dürr boilers have all been mentioned in previous letters, and the list would not be complete without the Belleville. Unfortunately the De Naeyer is the only one of these which is shown at work. Messrs. Delaunay, Belleville and Co. have made no change in their standard type since 1889; they still consider that large receptacles above the tubes, whether intended for steam or water, are a mistake, and that they diminish the security against explosion, which should be considered one of the chief merits of a water-tube boiler. They also maintain that by the use of an automatic feed-regulator, these reservoirs are rendered unnecessary. Their principal exhibit is a group of four boilers, which form one-eighth part of the total boiler power of the French ironclad battleship Bouvet, 14,400-horse power. Their test pressure is 1000 lb. on the square inch. In a list of the boilers recently manufactured by this firm, I observe that they have supplied those for H.M.S. Powerful and Terrible, each of 25,000-horse power, and also of the Sharpshooter, 3500-horse power.

Amongst their other exhibits are a small boiler with thirty-six tubes, working at 225 lb. pressure, for boats 33ft. long in the French Navy. They also show an eight-horse power portable engine, of which they are supplying a good many to Africa and to the mountainous parts of Italy. It has thirty tubes, and can be taken to pieces for mule transport, the heaviest piece only weighing 264 lb. It is put together entirely with bolts.

The machine tools, and especially the milling machinery made in different countries, do not differ so much as the water-tube boilers. Still, there are little variations between them, and each one has something worthy of notice. Only one French firm exhibits heavy machinery of this description—viz., the Usines Bouhey of Paris. In one of their machines, a vertical miller, they say that the tool revolves 195 times a second. The table in this is in three pieces, of which the middle part can be made to revolve separately, or the whole table can be set to travel automatically in any direction. In another vertical miller, weighing 15 tons, the whole of the front part carrying the tool bearer is movable. It weighs 50 cwt., but can easily be lifted by hand, by means of a lever with a ratchet wheel. The arrangement of the bed plate is the same as with the former one. They also show a machine for cutting or sharpening milling tools. In this there is a conical cutter which can be turned to any angle, and can be set exactly by means of a scale on the side. They have a large display of other tools similar to those described as being exhibited by Belgian makers of this class of machinery.

Another branch of engineering industry in which French manufacturers are making at least as much progress as those of other countries, is the production of special descriptions of bronze. In the attractively arranged stand of Messrs. Mathelin and Garnier, of Paris, some samples of bronze are shown, which seem to possess nearly all the qualifications required in good steel, with several others in which steel is wanting. This firm seem to have been experimenting in the same direction as Professor Roberts Austen, by examining the effect of the addition of minute quantities of manganese, aluminium, &c., to different descriptions of gun metal. More particularly they have been trying the effects of the introduction of phosphorus to an ordinary bronze in a state of fusion. For instance, they took two samples containing 88 parts of copper, 12 of tin, and 2 of zinc, a proportion regularly used in French arsenals. One of these samples on being tested showed a breaking strain of 11 tons, and an extension of 5 to 7 per cent. The same metal phosphorised by their process had a breaking strain of 17 tons, and an extension of 14 per cent.

Fig. 1



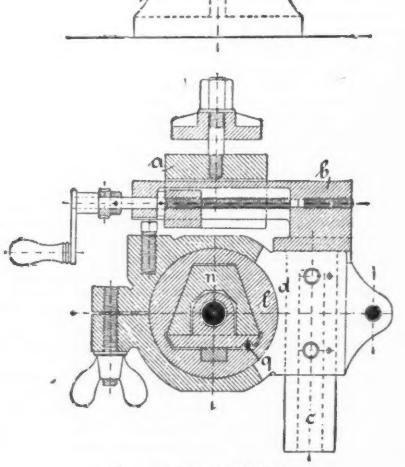


Fig. 2 - PITTLER LATHE

But their latest achievement, to which they have given the name of "Roma," from the Greek ρομα, "strength" is much superior to the manganese bronze, and phosphor bronze which they have shown at previous exhibitions. They do not give the exact constituents of this metal, but state that it contains copper, phosphorus, tin, aluminium, and manganese. Specimens of it are exhibited cast in various forms, rolled into bars and sheets, and drawn into boiler tubes or wires, as well as forgings which have been made from it. Roma is a pale yellow, has a specific gravity of 8·5, and melts at a temperature of about 1000 deg. C. As it does not corrode in sea water, and is not magnetic, it is preferable to steel for the hulls of steamers, &c. A set of test bars are shown which have given the following results:—

No. 1 Ordinary gun-metal, 10 to 13 tons per square inch breaking strain, 7 to 10 per cent. extension.
No. 2 Phosphor bronze, 17 tons per square inch breaking strain, 8½ tons elastic limit, 15 per cent. extension.
No. 3 Roma, cast in sand, 22 tons per square inch breaking strain, 16½ tons elastic limit, 43 per cent. extension.
No. 4 Roma, cast in sand, 24½ tons per square inch breaking strain, 19½ tons elastic limit, 21½ per cent. extension.
No. 5 Roma, cast in a mould, 28 tons per square inch breaking strain, 20 tons elastic limit, 40 per cent. extension.
No. 6 Roma forged, 31 tons per square inch breaking strain, 22½ tons elastic limit, 35 per cent. extension.
No. 7 Roma rolled, 35 tons per square inch breaking strain, 26 tons elastic limit, 7½ per cent. extension.

The exhibitors state that with drawn tubes they have had 37 tons breaking strain, 24½ tons elastic limit, and 16 per cent. extension; and with wire 62 tons breaking strain, 49 tons elastic limit, and 16 per cent. extension. Messrs. Mathelin and Garnier also exhibit a very pretty model of a torpedo boat, entirely constructed in Roma metal, and some photographs of screw propellers and other castings for naval construction. To one of these—the photograph of the screw for the Jaureguiberry, a casting weighing nine tone—is attached a copy of the official test made in May, 1893, showing a breaking strain of 24 tons, an elastic limit of 13 tons, and an extension of 21 per cent.

Messrs. Morane and Co., of Paris, show a number of hydraulic presses for different purposes. They have presses for making gas retorts, bricks, and cartridges, but their speciality is machinery for stearine. The first apparatus shown is a double hydraulic press for separating the stearine from the oleine. In this machine the engine is on one side of the press, and there is an automatic arrangement which, when the pressure is too strong, releases the water. The material is first pressed cold and then hot, the heat being applied by means of steam passing through thirty small plates in the press. There are several machines for making stearine candles, some of which are solid and of the ordinary shape, others have three oval holes about ¼in. by ⅛in. cast in them through their entire length. This arrangement is made in order to prevent guttering. The machine will cast a hundred candles at a time, and works continuously, as the wick is coiled on drums underneath the machine. They also show a very large press for stamping steel pans, &c., having a pump which will exert a pressure of fourteen tons on the square inch.

M. Leon Droux, of Paris, exhibits a complete set of apparatus for the manufacture of glycerine. This consists of an open pan in which the fat is melted, a steel retort, a set of six copper condensers, and a spiral cooler. A syphon connects the pan with the retort, and a vacuum being created, the melted fat is drawn into the latter. Superheated steam at a temperature of 190 deg. to 200 deg. Centigrade is then injected into the retort, and heat is also applied underneath. The products of distillation are drawn through the six condensers, passing from the top of one to the bottom of the next, any glycerine vapour remaining after the sixth is liquefied in the spiral cooler. The glycerine from the condensers falls into copper receptacles underneath; that in the first ones is usually of bad colour, and requires to be redistilled. The residues are drawn off into a separate receptacle, which is also in connection with the retort, so that they can be pneumatically returned to it, and redistilled if necessary. M. Droux also exhibits a copper retort for the distillation of fatty acids, produced by the decomposition of fatty materials. A novelty in connection with this still is that the residue is received in a specially designed airtight vessel, which prevents any risk of its catching fire.

M. E. Wauquier, of Lille, exhibits two descriptions of pumps, centrifugal and direct double-acting steam force pumps. The centrifugal pumps are specially designed to raise water to the height of 100ft. in one lift. In the double-acting pumps there are two pump barrels, with direct double-acting pistons, each worked by a steam cylinder with an ordinary slide valve. They are so arranged that the valve rod of one steam cylinder is driven from the rod of the opposite pump. By this means there is always an opening for the admission of steam, and consequently no dead point. There is the further advantage that the speed of the pump may be diminished considerably without fear of its stoppage. One pump exhibited, intended for feeding marine boilers, will work against a pressure of 140 lb.

At the same stand there is shown a model of an interesting invention by M. P. Walraf, for taking up the *vis viva* of a tramcar when the brake is put on, and causing the wheels to revolve and to start the car directly the brake is removed. It consists principally of an intermediate shaft, on which a strong spiral spring is coiled. The shafts carrying the front and back wheels gear by means of intermediate pinions into a wheel on this shaft. Directly the brake is applied, it causes the spring on the intermediate shaft to tighten, and as long as the brake is on, it prevents the spring from uncoiling. Directly the pressure of the brake is removed, the spring causes the intermediate, and consequently the main wheels, to revolve, and thus starts the car. The extra weight of this apparatus is about 3 cwt.; but the inventor is endeavouring to simplify it, and thus make it lighter.

## THE FEDERATED INSTITUTION OF MINING ENGINEERS.—NEWCASTLE MEETING.

AT the resumed meeting, Mr. Morgan W. Davies' paper on "Timber Bridges and Viaducts," Mr. Edwin Gilpin's paper on "Explosions in Nova Scotian Coal Mines," and Mr. J. R. Wilson's paper on "The Shaw Gas Tester for Detecting the Presence and Percentages of Fire-damp and Choke-damp in Coal Mines, &c.," were considered. The first paper dealt with the characters of the various kinds of timber suitable for bridge construction at the disposal of the British mining engineer; with methods of making tests and computations to ascertain the suitability of such timber for the purpose; and with various modes of bridge construction, and the points and calculations that should be contemplated before deciding on the mode of construction to be adopted in any particular case.

In his paper, Mr. Edwin Gilpin, who is a deputy commissioner and inspector of mines, pointed out that there are three widely separated coal-mining districts in Nova Scotia, but that the geological horizon of each is the middle carboniferous. The Cape Breton coals are almost invariably coking and adapted for gas-making, whilst the Pictou and Cumberland coals are more or less free-burning; the latter two are associated with beds of shale, the former with a larger proportion of beds of sandstone.

The following average analytical numbers give a general indication of the differences of these coals:—

| | Cape Breton. | Pictou. | Cumberland. |
|---|---|---|---|
| Moisture | ·75 | 1·19 | 1·46 |
| Volatile combustible matter | 37·26 | 29·10 | 33·69 |
| Fixed carbon | 58·74 | 60·63 | 59·35 |
| Ash | 3·25 | 9·34 | 5·50 |

The author then proceeded briefly to enumerate, with more or less important and interesting detail as to localisation and prevailing conditions, the principal explosions that have occurred in these districts, from about the beginning of this century to the present time. In Cape Breton district there have been a number of cases of ignition of gas, of which one only—in 1878—is classed as an explosion, and in no case is dust considered to have played an active part. In the Pictou district, which is very gasey, fifteen fires and explosions are recorded, and a copy of the special rules in force in 1840 is appended to the paper. The rules, curiously, are the same as those in vogue in South Hetton Colliery at the same period, and show that then, as now, the use of gunpowder was intimately connected with fire. One explosion in the Cumberland district is chronicled. It is noteworthy that in the author's experience no explosion in Nova Scotia can be attributed to coal dust alone, but a number of them have had their area and their destructiveness to life materially increased by coal dust.

The apparatus described by Mr. Wilson appears to be well known and highly appreciated in the United States. It is made of iron and brass, measures about 2ft. square, weighs 90 lb., and costs £100. It consists of a pair of air pumps, one with a stationary cylinder and constant stroke of piston, the other with a movable cylinder that can be set between two graduated bars, so as to pump any desired percentage of gas. Both pumps are operated by the same swinging arm, which is also one of the graduated bars, and the sum of the volumes of gas pumped from the two cylinders always equals 100. The stationary cylinder serves for the gas to be tested, the movable one for the standard gas. When the pistons are operated the product of the two cylinders, in testing for fire-damp, is pumped through a mixer into an igniting chamber, which is provided with an orifice on one side in front of a gas jet. If the mixture pumped in is ignitable, the expansion induced by the heat of ignition propels a loose piston-head, held in place by a bowstring against a gong at the end of the chamber, and an addition or subtraction of 0·1 per cent. will cause this gong to ring or remain silent. The sample of gas from the mine is taken with a diaphragm pump, and stored in a six-gallon rubber bag; to make a test the bag is attached to the stationary cylinder, and the movable cylinder is adjusted to deliver an explosive proportion of standard inflammable gas, then if the detonation is too loud, or there are other indications of the presence of much gas in the mine air, the proportion of standard gas is reduced until a normal ring of the gong is obtained, and the percentage of gas is then ascertained by noting the position of the movable cylinder by means of the graduations on the bars.

It is claimed that with this apparatus even an unskilled operator can estimate, within a minute or so, whether a gas is wholly fire-damp or only carries 0·1 per cent. of that gas, that is, can obtain results accurate to the 0·001 part. With it, too, mixtures might be accurately prepared to test the sensitiveness of safety lamps, and the noxious proportions of sulphuretted hydrogen, carbonic anhydride, carbonic oxide, &c. Whilst by the same process of admixture, and by means of suitable indicators, the proportion of any of these gases in an atmosphere can be, it is said, accurately ascertained. Professor Bedson, in absence of any practical knowledge of the apparatus, had misgivings as to the delicacy claimed. Mr. Ashworth and others commented on the cumbersomeness and unwieldly character, moreover disapproved, of testing by firing, and drew attention to well-known appliances which could do most—as regards fire-damp and choke-damp—of what was claimed for this apparatus. Mr. H. G. Graves drew attention to the fact that M. Le Chatelier had obtained results with the Shaw apparatus which were as accurate and as constant as the results obtained with the Le Chatelier endiometric apparatus, which is in use both in France and Belgium, and depends, like the Shaw tester, on the ignition of mixtures of known volumes of mine gas with known volumes of inflammable gas.

The excursions included a sail, on the Wednesday afternoon, up and down the Tyne, and permitted of the examination and admiration of the vast operations of the Tyne Commissioners, and a cursory but interesting view of the general industries on the river banks. The striking features of the river were the high-level and swing bridges, the great grain stores, the extent of many of the works operated by individual corporations, the numerous coal staiths and spouts, and the large number of steamers laying up. On the Thursday opportunity was given the visitors to examine the Northumbrian methods of winning and shipping coal, the North Seaton, Cambois, Ashington, New Hartley and Seghill Collieries, and Blyth Harbour being thrown open for inspection. At North Seaton the yard seam, 2¼ft. to 3ft. in thickness, at a depth of 558ft., and the low main seam, 4ft. to 5ft. thick, at a depth of 750ft., are worked, the former on long wall, the latter on the board-and-pillar system; the output is 1100 tons a day. The winding engine is vertical and condensing, with cylinders 60in. diameter and 7ft. stroke, and a drum of 22ft. diameter; it draws four tubs of 21 cwt. gross weight at a time; an endless rope counterbalance is used under the cages. The haulage is the main-and-tail system in the low main seam and the endless rope system in the yard seam. For pumping there are a compound condensing Worthington engine underground, with high-pressure cylinders 18in. diameter, and low-pressure cylinders 30in. diameter, and rams 9in. diameter with 30in. stroke, which forces 750 gallons of water a vertical height of 800ft. through a 10in. wrought iron main; a vertical beam engine, cylinder 78in. diameter and 6in. stroke, held in reserve; and an electric pumping plant, with an engine at bank with cylinder 13in. diameter and 10in. stroke, driving a Tyne dynamo connected to an underground three-throw pump 8000ft. distant. The pump is worked by worm gearing, has rams 9in. diameter and 15in. stroke, and pumps 250 gallons of water a minute. The screening plant comprises jigging screens, picking belts, mechanical tipplers, 200-ton Robinson coal washer, &c. There is also an electric light plant. At the Cambois Colliery the low-main seam, 4½ft. to 5ft. thick, is worked on the board-and-pillar system, with main-and-tail haulage, at a depth of 630ft., and mainly under the sea; the output is 1200 tons per diem. The winding engine is vertical and condensing; cylinder, 65in. diameter and 7ft. stroke, with a drum 22ft. diameter, draws the same load of tubs as the North Seaton engine. The underground pumping engine has two cylinders 22in. diameter, with 5ft. stroke and rams 9in. diameter and forces 400 gallons of water a minute to a vertical height of 650ft. through 13in. pipes; whilst the electric pumping plant at bank consists of a Robey trip-gear engine and a 40-unit Tyne dynamo, which drives six underground pumps at distances varying from 3600ft. to 6900ft., necessitating the use of nearly eight miles of cable. There is an electric lighting plant and a 250-ton Robinson coal washer. The colliery is connected by a private line with the company's shipping ports at North Blyth.

At Ashington Colliery the low main seam is at a depth of 540ft., and in spite of some rather ancient engines, 4300 tons of coal are drawn from three shafts daily. The haulage is on the endless-rope system, and the underground pumping is done partly by compressed air, partly by endless ropes, the feeders being raised to the surface by pumps 25in. in diameter. Mechanical bars and forced draught are used under the boilers. Jigging screws and travelling belts and a Bell and Ramsay washer are employed in preparing the coal. Electric light is supplied in many departments. A feature of this colliery, which, by-the-bye, is one of the most successful in the district, is the model village attached to it, consisting of long rows of neat cottages, mostly built of fire-brick made at the colliery by the semi-dry process. A narrow gauge railway runs at the back of each row of cottages, and serves for running a locomotive and trains of tubs, for the distribution of coal to the workmen and others, and also for the scavenging of the village. At the New Hartley Colliery one was struck by the neat housing and the well planned arrangement of the various departments on the surface, and the attention paid to the maintenance of pumps, &c., in good condition. The yard coal is worked from the Hastings pit at a depth of 330ft. on the longwall system, with an endless chain haulage; all waste obtained in the mine is used as stowage, so that no spoil heaps appear on the surface. The winding engine is horizontal, with two cylinders, each 28in. diameter and 54in. stroke, with a drum 14ft. 4½in. in diameter. The cages are two-decked, carrying four tubs, each containing 8½ cwt. of coal. A compound differential pumping engine on the surface, with cylinders 24in. and 44in. respectively in diameter, and 7ft. stroke, works two 17½in. rams the same stroke at the pit bottom, by means of quadrants and spears, and forces about 500 gallons a minute a vertical height of 384ft., but it has pumped 1570 gallons per minute. A 30ft. Guibal fan is used for ventilation, and produces 108,000 cubic feet of air per minute under a water gauge of 1·30in. Electric light is supplied on the surface and underground. The Melton pit, tapping the yard seam at 336ft., is being sunk to the low main seam. At Seghill the Blake, yard, and low main seams are worked; the output is 1200 tons a day from two shafts. The ventilating, pumping, and haulage engines are of special interest. The ventilation was until recently done with furnaces, but now it is effected by an open-running fan 35ft. in diameter driven by a Corliss engine, described in vol. vi., page 48, of the Institution's "Transactions." It has one steam cylinder, 16in. in diameter and 3ft. stroke, with sugar-tongs trip valve gear. The engine is controlled by a governor which automatically varies the cut-off and maintains a regular speed, even when the steam pressure varies 20 lb. per square inch. The speed is readily varied by altering weights placed on the governor, and can be effected while the engine is running.

For pumping, a vertical engine, with a cylinder 9½in. in diameter, 9in. stroke, running at 200 revolutions per minute, drives a 15-horse power dynamo producing a current of 460 volts. The electric energy is transmitted through a $\frac{7}{16}$in. insulated cable to a 10-horse power motor placed in the low main seam, nearly a mile distant from the shaft. This motor drives a three-throw ram pump delivering 100 gallons of water per minute to a vertical height of 120ft. through two pipes 4in. in diameter. The useful effect is 32 per cent. A few electric incandescent lights are attached to this dynamo. The haulage, on the main-and-tail-rope system, is worked by a horizontal engine, with a cylinder 13½in. in diameter and 30in. stroke; steam jacketed, and fitted with valve gear controlled by a governor, which automatically varies the cut-off, and maintains a constant speed of engine. The speed may be varied from 70 to 100 revolutions per minute by altering a spring attached to the governor, even while the engine is in motion. When not hauling, the tail-rope drum can be put out of gear, and a clip wheel put into gear, and the power transmitted by an endless wire rope to the main pumping-engine in the low main seam. This engine, when running at 70 revolutions per minute, indicates 66-horse power, and pumps 200 gallons of water per minute from a depth of 510ft. A similar engine works the endless rope haulage in the yard seam with over two miles of rope. A smaller engine, with a cylinder 10½in. in diameter and 22in. stroke, works the endless-rope haulage in the Blake seam with over six miles of rope. All these engines work by steam at a pressure of 100 lb. per square inch, and the steam for the whole collieries is generated by four Lancashire boilers, fired by hand with small coal.

A good general idea of the extent, capacity, working, and equipment of the Northumbrian collieries was obtained from these visits, whilst a visit to Blyth Harbour, round which the members were taken in steamers, showed what enterprise and engineering ability had done to facilitate the shipment of the vast output. From a comparatively insignificant sea port, Blyth has grown to be one of the most important coaling ports on the North-East Coast, and ships, it is said, more coal than Hull, Grimsby, and Goole put together. It is situated at about the centre—measuring north and south—of the Northumberland coalfield, and about eight miles north of the river Tyne. There are upwards of twenty collieries within a radius of four miles, and about twenty others in the neighbourhood, for which Blyth Harbour is the natural port of shipment. There are fourteen coaling-spouts at the harbour, most of them being upon the most improved principles, and adapted to load into two hatchways of a vessel at one time, and having a depth of water alongside of 29ft. to 34ft. at high water. The entrance channel from the sea has a depth of 28ft. at high water. By the continuous improvement of the harbour, trade has developed so rapidly that it has been found necessary to provide further accommodation for vessels and greater facilities for shipping coal. The Harbour Commissioners are now increasing the deep-water area of the harbour to the extent of thirty-five acres, and are providing new coaling staiths capable of shipping 2,000,000 tons of coal per annum, and deep-water import and export wharves with railway sidings and connections. There are quays for the discharge of timber, ballast, and general goods; five graving docks for the repair of vessels, and land available for factories, shipbuilding yards, &c. Both sides of the harbour are connected with the North-Eastern Railway system, and by it with all parts of the country. The remarkable growth of this port will be gathered from the fact that in 1883 the shipment from the harbour for the year was 146,264 tons, whilst the shipment last year was 2,342,020 tons. It may be mentioned that the party were enabled to make this large round of visits through the liberality of the directors of the North-Eastern Railway, who provided a special train for the purpose.

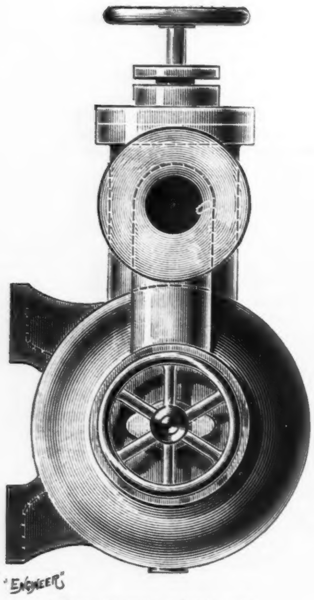
It is a well-known fact that the North of England Institute of Mining and Mechanical Engineers have been conducting, at their own expense, important experiments on flameless high explosives. The labours of the committee, so far, and of which a report is now in the press, have been directed to the behaviour of carbonite, ammonite, securite, bellite, westphalite, roburite, and Ardeer powder, also gunpowder, when fired into atmospheres under atmospheric pressure, containing from 1 to 6 per cent. of mine gas or coal gas. In order to give the engineers assembled in Newcastle an opportunity of judging the character of the methods of investigation, invitations from the Flameless Explosives Committee were issued for last Friday to view the appliances and witness some experiments. It is not our intention to anticipate the report in any way; we shall therefore restrict our remarks to some of the interesting operations and arrangements we observed. The scene of the experiments is a disused brickworks, and its general appearance of dilapidation gives it an air singularly appropriate to the purpose to which it has now been applied.

The firing chamber consists of a cylindrical tube, 100ft. long and 3ft. in diameter, made of boiler plates, and a cannon, mounted on a carriage and capable of being brought close up to one end of the chamber, serves for holding and firing the charge of explosive. The chamber has safety vents at intervals along the top, which are closed by wooden plugs loosely knocked in, whilst, in addition to these, several ports glazed with thick glass extend along the side, for observing the interior from an adjoining dark room, the parting brick wall having holes in it corresponding with the glazed ports. There are other arrangements: for ensuring the delivery of a measured volume of gas into a definite volume of air; for effecting the perfect admixture of the gaseous mixture; for warming the gaseous mixture; for taking samples of the mixture before or after explosion; for taking its temperature; for providing for the presence of dust of any kind in suspension, or *in situ*, and for other purposes, all of which will be duly described in the report, and all of which indicate how carefully and thoroughly the investigations have been planned and executed.

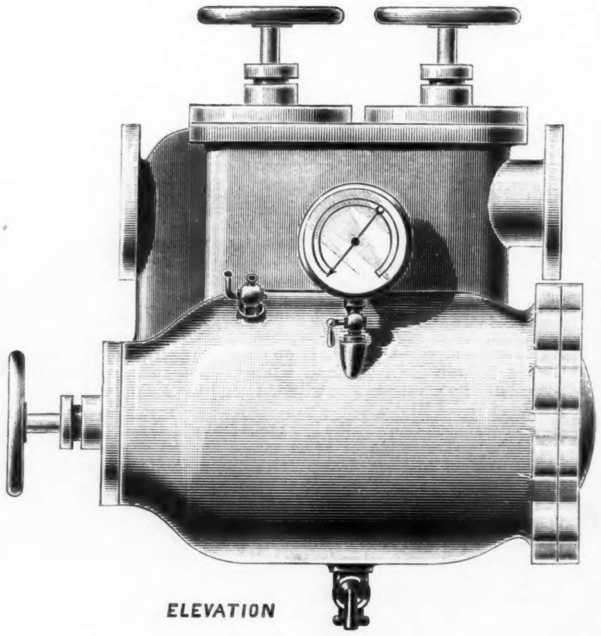
On Friday experiments were performed with the firing of gunpowder into the ordinary air; into an inflammable mixture of mine gas, direct from Hebburn Colliery, and air; into ordinary air with coal dust in suspension; into ordinary air with coal dust *in situ;* the last three being done in duplicate to enable the visitors to view the effect both in the inside of the firing chamber and outside it. Before commencing any experiment, the far end or mouth of the firing chamber was covered up with a sheet of brown paper. In the air, with gunpowder alone a bright flash was observed in the chamber, and the brown paper was blown off the end; when dust was present, whether in suspension or *in situ*, the flash was considerably brightened and lengthened, and not only was the brown paper blown off the end, but a huge cloud of smoke was propelled for more than thirty yards from the mouth of the chamber, and many of the plugs were forcibly projected from the safety vents, being followed by rushing columns of thick black smoke, and in some instances flame; very suggestive of the explosiveness of mixtures of coal dust and air. The force of the explosion of the fire-damp and air was equally well exhibited, and in this case two flashes were observable, the first being due to the ignition of the gunpowder, the second to the ignition of the gaseous mixture. The experiments were very successful; moreover, all points were well explained, and the apparatus lucidly described by Mr. J. L. Hedley, H.M. Inspector of Mines. All present were much gratified, and have had their appetites sharpened for the speedy devouring of the report when it appears. This was an interesting and fitting termination to the agreeable and instructive visit of the Federated Institution to Newcastle-upon-Tyne. The next meeting of the Institution is to take place in February, in South Staffordshire.

# RANKINE'S MARINE FILTER

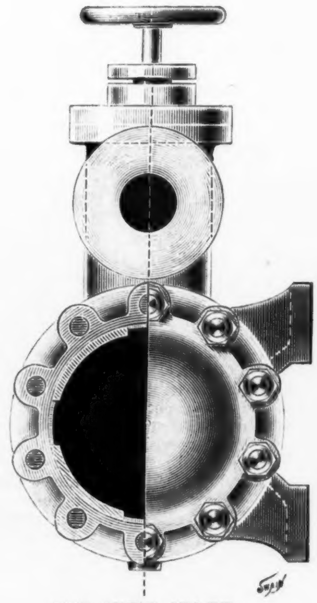
MR. D. RANKINE, WATER-STREET, LIVERPOOL, ENGINEER



END VIEW OUTLET



ELEVATION



END VIEW INLET

## RANKINE'S MARINE FILTER.

RANKINE's marine filter, which we illustrate by the accompanying engravings, is an apparatus for separating and extracting air, oil, and greasy deposit from the feed-water before entering the boilers, and is fitted on the delivery side of the feed-pump, between the feed-pump and the feed-water heater or boilers, but may be fitted on the suction if necessary. The apparatus consists of a cylindrical gun-metal or cast iron filtering box divided into two compartments, having in the outlet compartment a diaphragm bored out to fit the tapered ring of the filtering cartridge, and a seat at the inlet end into which the cartridge fits. It is also fitted with a steel manhole door for cleaning purposes and two drain cocks. An arrangement of inlet, outlet, and bye-pass valves is fitted, the latter being so arranged that the feed-water may be passed at any time into the boilers when necessary to clean the filter.

The internal arrangement is a portable cartridge, and is made as follows: — A strong perforated tube is fitted into a tapered ring at one end, and at the other end closed by a turned washer of malleable iron; these are mounted on a spindle and firmly fixed together. This forms the cartridge proper. Two or more turns of the filtering cloth, usually Turkish towelling, are wound round the perforated tube and further secured by a steel strip, hinged at one end and buttoned at the other. The cartridge is now ready for shipping into place. A packing ring is put under the collar to prevent water passing through the hole for the spindle in the external casing, and the cartridge is drawn tight to its seat by the handle.

On leaving port the inlet and outlet valves are open and the bye-pass valve closed. The feed-water will then pass through the inlet valve into the annular space around the cartridge, and freely through the filtering cloth and holes of the iron tube, and so out at the base of the cartridge to the outlet valve and on to the boilers. The pressure gauge will register at the commencement simply the boiler pressure, but as the filtering cloth becomes charged with grease the pressure gauge will indicate the extra pressure set up by the filtering cloth, and when it shows 15 lb. above the boiler pressure it will indicate that the cartridge is foul and requires changing. To clean the filter the bye-pass valve is opened, and the outlet and inlet valve shut down. The feed-water will then pass freely into the boilers. The manhole door is then taken off and the handle at the inlet end is turned; the cartridge then travels out with the screw.

The linen cloth coverings are thus easily removed and replaced. They are of large area, and thus do not sensibly increase the pressure against which the pumps have to work.

## ABSTRACTS OF CONSULAR AND DIPLOMATIC REPORTS.

*France: British goods in Nantes.*—It is surprising that so few English commercial houses send representatives to this part of the country. English cutlery and hardware are highly esteemed, and would find a ready sale if properly brought to the notice of the public by such channels as commercial travellers. English goods are imitated in France with a certain degree of success, but the prices are not much lower, and the quality in most cases is vastly inferior. It is only the better class of goods which would find a market here. The cheap kinds would not be able to stand the high protective duty.

*France: Canals of.*—In 1879 a law was passed by which the State was authorised to purchase all the larger canals of the country, so that the traffic upon them, most of which at that time was still in private hands, should gradually be freed from all charges. Whilst the provisions of this law were carried out in most parts of the country, and the traffic on seven-eighths of French canals became free from dues, a different course has been adopted by the Government in south-western France. Here, instead of taking into its own hands the rather important canal traversing the country from west to east—the western portion being called "Canal Latéral à la Garonne," and the eastern the "Canal du Midi"—the Government made an arrangement with the South of France Railway Company, by which the latter, instead of receiving a certain sum granted by the State as a subvention to all the large French railway companies, became proprietor of the western portion, and the eastern portion was left in the hands of another private company. This canal is 60ft. wide, with an average depth of from 6ft. to 7ft. It connects Bordeaux with Cette, but is consequently entirely used by barges and vessels of a very small class. The traffic on both portions of this canal has continued to be subject to certain charges, and the South of France Railway Company is considered to have systematically favoured the traffic on the railway to the detriment of that on the canal, which, according to the prevalent opinion of the agricultural, commercial, and industrial classes in the Bordeaux district, has become useless to them. These classes have for some years demanded that the Government should take the canals of Southern France into its own hands, and that the traffic thereon should be freed.

The project of connecting the Atlantic and the Mediterranean by a ship canal of sufficient dimensions to afford a passage to the largest merchant vessels, and the largest war vessels of the French navy, has assumed a more definite shape, through the formation of a French company, with the intention of constructing and maintaining such a canal without any guarantee or pecuniary aid from the French Government, if the public will provide the money for the work. The company has invited French engineers to compete in drawing up plans and estimates of the projected canal, and proposes that none but French engineers, contractors, workmen, and materials shall be employed in the work, which, if it could be carried out at a reasonable cost, the "Canal des Deux Mers" would, especially for French interests, be a very useful undertaking, apart from its importance in time of war, as it would give a very great impulse to the development of the agricultural, commercial, and industrial interests of the fertile districts of Southern France, besides offering certain advantages to shipping, both of France and other countries. It is questionable whether the cost of the undertaking would not be out of all proportion to the advantages expected from it, and if sufficient money to carry the enterprise into effect can be raised. At a meeting held at Toulouse in the early part of the year, and attended by numerous senators, deputies, and delegates from commercial and other public bodies of South-Western France, it was resolved that until the question of the redemption of the existing canals of Southern France shall have been satisfactorily settled, that of the proposed construction of the "Canal des Deux Mers" can not be considered. At Bordeaux the opinions of the leading classes are not favourable to the project, it being thought that the undertaking, if carried out, which is unlikely, would be a financial failure.

The idea of constructing a maritime canal between Dieppe and Paris has again been mooted by those who cite the Manchester Ship Canal as an example of what courage and perseverance can effect. A summary report on the proposal of M. Jacques, describing the project of a maritime canal from Paris to Rouen to be one of public "utility," was recently laid upon the table of the Chamber of Deputies; but the Chambers of Commerce both of Dieppe and Rouen wrote to the Deputies and Senators of the Department, reminding them of the energetic protest they made against the scheme some years ago, and declaring that the arguments then adduced are still in force, and begging them to use their influence so that the scheme may again be negatived by Government.

The deepening and widening of the canal from Ouistreham to Caen, so that larger vessels may come to the latter place, has not been commenced, but good progress has been made with the preliminary formalities, and it is expected that this important undertaking will be begun this year.

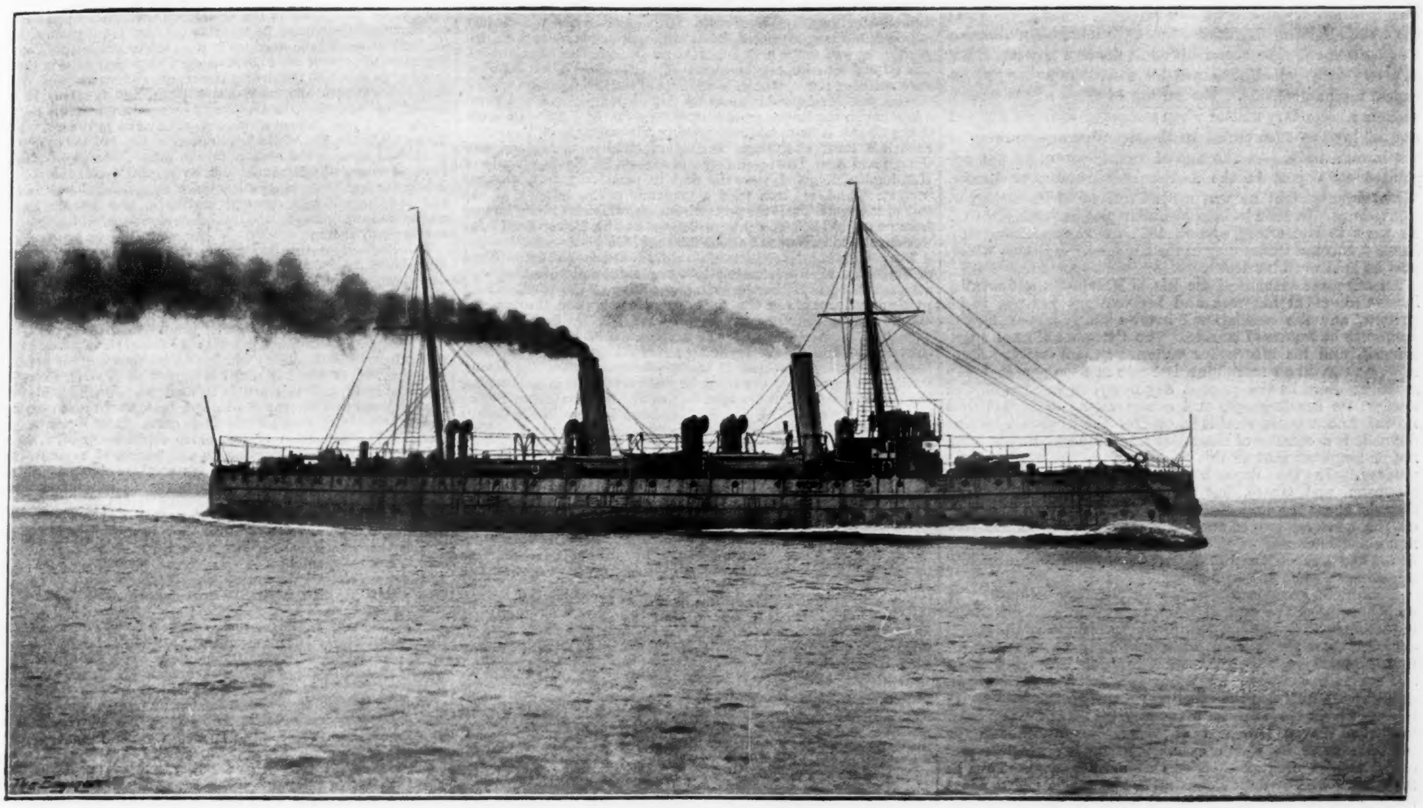
The traffic on the Tancarville Lateral Canal, which fell from 440,330 tons in 1891 to 373,096 tons in 1892, last year rose to 445,978 tons.

Since the opening of the Maritime Canal de la Basse Loire, a great number of large sailing vessels and steamers have passed through it, and it is generally considered by those interested in the trade of Nantes that the success of the canal is assured, and that Nantes will recover its former position as a busy port. The increase in shipping entered last year was 113,935 tons, or 130·17 per cent. over the figures of 1892. The increase in sailing vessels was 2818 tons, or 8·54 per cent., and the steamers 111,117 tons, or 195 per cent.

THE re-construction of H.M.S. Monarch is approaching completion, and she will be ready for commissioning in a week or two. An examination of her hull showed that it was in a remarkably sound condition, but her engine and boilers were worn out. These have now been replaced by new ones, and she has been thoroughly repaired at a comparatively small cost, with the result that she is now an efficient battleship.

# THE ARGENTINE CRUISER PATRIA

MESSRS. LAIRD BROS. BIRKENHEAD, BUILDERS AND ENGINEERS



## THE ARGENTINE CRUISER PATRIA.

The Argentine cruiser Patria, built and engined by Messrs. Laird Bros., of Birkenhead, has been put through her official speed trials with eminently successful results, the procedure of the trials being similar to that laid down by the British Admiralty, armament and all normal weights on board.

The full power forced draught trial of three hours' duration was made on the Clyde last Friday week, six runs over the Skelmorlie mile giving a mean speed of 20 575 knots, with a mean of 233·4 revolutions per minute, whilst the record for the three hours' continuous running was 20 56 knots, with a mean of 233·5 revolutions—this exceeding by one knot the guaranteed speed of 19·5 knots. Nothing could have been more satisfactory than the working of the engines and boilers, and the almost entire absence of vibration of machinery and in the ship.

The official natural draught trial was made in Liverpool Bay the week before, during boisterous weather and with a heavy cross sea, when, during eight hours' continuous steaming, 17·6 knots, and with 201 revolutions, during six consecutive runs over the base between the outer lightships, 17·915 knots was recorded. The ships are 8·1 knots apart, in exposed positions, and form necessarily a difficult course to steer accurately; the speed, however, was one quarter knot over contract. In order to test this a further natural draught trial was made on Friday last, when four runs were made over the Skelmorlie mile at 190 revolutions—which it was estimated would give 17·5 knots, the contract speed—with the result that 17·772 knots was recorded, with 11 revolutions per minute less than when running the trial in Liverpool Bay.

The Patria is a cruiser similar to the Halcyon and Harrier class, of which some half-dozen are being added to the British Navy, but, on the recommendation of Messrs. Laird, the Argentine Government decided to have the poop and forecastle joined, forming a complete spar deck, which adds much to the general comfort and seaworthiness, makes it possible to place the broadside guns fully 7ft. higher above water, and affords accommodation available for the carrying of troops or reliefs when required, whilst the larger engine power gives a knot per hour greater speed. The principal dimensions are:—Length, 250ft.; beam, 31ft. 6in.; draught of water, with armament and all normal weights on boards, 10ft.—the screws do not project below the line of keel—bunker capacity for 250 tons of coal, or 4000 knots range of action.

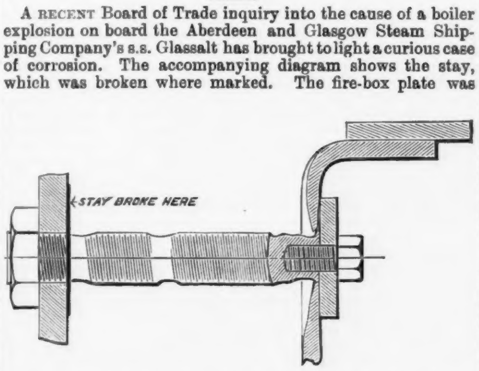
The machinery consists of two sets of tri-compound engines. The main condensers, evaporators, and distillers are of brass, and the auxiliary machinery and general arrangements are similar to the builders' well-known type of high-speed engine, of which the Rattlesnake was the original. The boilers are four in number, of the dry bottom locomotive type, worked on the closed stokehold system, the air pressure for full power not exceeding 2½in. Each pair of boilers and each set of engines are in separate compartments.

The armament is of the best and newest type. The guns are two 4·7in. of Armstrong's make, the four 8-pounder and two 3-pounders being Maxim-Nordenfeldt, carried on the spar deck, and two 1in. machine guns on the bridge, whilst the torpedo equipment consists of one bow tube and four broadside tubes carried on the main deck, worked through specially designed ports, the torpedoes being made by Whitehead, of Fiume, of the latest 18in. pattern. The completion of every detail of arrangement for the efficient and convenient working of this small but powerful cruiser reflects great credit on the builders, who designed all the details of the vessel and machinery, and adds another success to their well-earned and leading position as naval ship constructors.

There were on board during the trial Captain Manuel Barraza, Captain Diaz and Captain Lagos, and Mr. T. W. R. Hughes, representing the Argentine Naval Commission, Mr. John Laird, Mr. Bevis, and Mr. Bevis, jun., representing the builders, Mr. F. D. Hobbs, R.N., and Mr. W. T. Hocken, R.N., of Devonport Dockyard, and Mr. C. C. Scott, of Greenock.

## BOILER EXPLOSION.

A recent Board of Trade inquiry into the cause of a boiler explosion on board the Aberdeen and Glasgow Steam Shipping Company's s.s. Glassalt has brought to light a curious case of corrosion. The accompanying diagram shows the stay, which was broken where marked. The fire-box plate was also so corroded that the stay had no hold on it, and was consequently blown out, scalding the chief engineer, who was in the combustion chamber at the time, so severely that he died two days afterwards. The report says:—"As to the failure of the stay, it had much the appearance of having been cut at one time until nearly severed, and very little of the metal remained." "From evidence obtained," the report goes on, "it appears that on the passage to St. Malo there was a leakage from the centre fire-box of the boiler. On the vessel's arrival at her destination it was discovered that the leakage was coming from the stay second row from the bottom; this they repaired, in order to stop the leakage, by fitting a ⅝in. pin into centre of stay, and making a joint with a small plate or washer. On the morning of 29th March, while raising steam, water was observed coming from the centre fire-box. The chief engineer, when the pressure was about 45 lb. per square inch, went into the back in order to ascertain where the boiler was leaking, taking with him a hammer and two caulking tools. It is stated that he could not have been in over a minute when the explosion occurred. Whether he had been working at the stay or not, the fireman who was in attendance cannot say, as he states he did not hear him using the hammer."



No one connected with the ship seems to have been aware of the previous condition of the stay, and no evidence was obtained regarding its condition when it was first fitted. The boiler was built by Messrs. Hall, Russell, and Co., engineers and shipbuilders, Aberdeen, in the year 1883, under the inspection of Lloyd's Registry, and was last inspected in Elsinore, in May, 1893, by one of the Registry's surveyors.

## THE ARMOUR-PLATE SCANDAL.

Last week the Chairman of the House Committee on Naval Affairs submitted a preliminary report on the alleged frauds in the manufacture of armour-plates by the Carnegie Company. The charges are summarised thus:—"The plates did not receive the uniform treatment required by the specifications of the contract; that false reports of the treatment of plates were systematically made to Government inspectors; that bolts did not receive double treatment required; that specimens taken from the plates, both before and after treatment, to ascertain the tensile strength of each plate, were stretched, without the knowledge of the Government inspectors, so as to increase their apparent tensile strength when actually tested; that false specimens, taken from other plates, were substituted for specimens selected by Government inspectors; that the testing machine was manipulated by the order of the superintendent of the armour-plate mill so as to increase the apparent strength of the specimens; specimens selected by the inspectors were re-treated before being submitted to test; plates selected by inspectors for ballistic test were re-treated with the intention of improving their ballistic resistance, without the knowledge of the Government inspectors; that in violation of the contract, pipes or shrinking cavities, erroneously called blow-holes in plates, were plugged by the contractors and the defects concealed from the Government inspectors; that the Government inspectors' stamp was either duplicated or stolen and used without the knowledge of the inspectors, and that the Government inspector, in inspecting bolts, was deceived by means of false templets or gauges."

Concerning these the report states that the first charge, that the plates did not receive uniform treatment, is admitted, the explanation being that what was wanted was uniform *results.* The second charge, that of false reports, is held to be proved by the rough records of the company itself of over 700 plates and lots of bolts. Over 95 per cent. of the records examined show changes of the reports to be made to the inspectors, evidently for the purpose of deceiving the inspectors. The third charge as to the double treatment of the bolts is held to be proved. The fourth charge, as to preliminary pulling of the tensile systems, is admitted, but Superintendent Schwab says that it was done without his knowledge or sanction, although he would not have objected to it had he known it. The charge that false specimens were substituted is practically admitted, but held by Superintendent Corey to have been of small importance. The charge that the testing machine was "jockeyed" is also admitted, but it is claimed that the manipulation was legitimate. The charge of re-treatment of specimens is held to have been proved. Superintendent Corey admits that plates selected for ballistic test were re-treated without the knowledge of the inspectors, but says that this was done, not for the purpose of improving them, but as an experiment. The charge of plugging blow-holes is admitted, but it is claimed that the plates would pass the requirements of the ballistic test. The charge that the inspector's stamp was duplicated or stolen is not sustained, nor is the charge that the inspectors were deceived by false templets or gauges. The committee considers the Government inspectors to have been negligent in their duty, but not corrupt. It was recommended that the Secretary of the Navy be directed to remove certain specified plates now in place on various vessels and submit them to ballistic test, and that he be authorised to pay the costs of such tests from money heretofore appropriated for the increase of the navy. The resolution covering this point was adopted by the House.—*Railroad Gazette.*

Dividends in the Birmingham District.—A return which has been prepared of the dividends of public companies in the Birmingham district in respect of each half-year during the past two years is interesting reading. It shows that on the whole, though dividends have decreased, our local companies have stood their ground fairly well, and better than in some instances might have been expected, remembering that the period was one of constantly declining trade. Collieries have improved their position. The tube and metal rolling companies have fared badly. On the other hand, Muntz's Metal Company and the Mint maintain their distributions—the former at 10 per cent., and the latter at 7 per cent. The cycle manufacturing concerns, which formerly paid such handsome dividends, are nearly all down, the result of the excessive competition. Steel making and constructional engineering establishments also mostly tell an adverse tale. But the Horsely Engineering Company, Tipton, is a noteworthy exception. This firm has augmented its dividends of late years from 5 and 6 to 7 per cent. The principal changes in the railway rolling stock group are in a downward direction, but the Patent Nut and Bolt Company, Smethwick, maintains its reputation as one of the most wonderfully prosperous manufacturing concerns, not only in the Birmingham district, but in the whole country, by still declaring 10 per cent. dividends.

## HERMAN LUDWIG FERDINAND HELMHOLTZ.

On the 8th inst. died at Charlottenburg, Professor Helmholtz, in the seventy-fourth year of his age. The mere list of the papers which he has written would suffice to fill a page of THE ENGINEER. His reputation extended to every portion of the civilised globe. His father was a German, his mother an Englishwoman. He began his adult life as a physician, but at a very early period he turned his attention to the physiological mechanical side. The curing of those who were sick became a secondary matter when compared with the study of natural laws as exemplified in the structure and working of the human body. At the age of twenty-seven, he was appointed to a post in the Anatomical Museum of Berlin. When twenty-eight he was made Professor of Physiology at Konigsburg. In 1856 he held a similar post at Bonn. In 1859 he went to Heidelberg, and in 1871 he was appointed Professor of Natural Philosophy in the University of Berlin, which post he held until his death.

An adequate account of the life of Helmholtz and a satisfactory *résumé* of his work and his writings has yet to be written, and the writing will involve much labour, for the ground to be traversed is wide. The Professor did not spare himself, and his biographer will not get off easily. Here, now, we can do no more than indicate in a very general way what he did. In the present day everyone speaks glibly of energy, its development, and conservation. The fact that no one knows quite what it is, or how the word can be best defined, is a matter of secondary importance. But it must not be forgotten that all this popular use of the word is quite modern. In the days before Faraday, Tyndall, Joule, Thomson, and Grove, but little was known or taught or thought about the subject. Helmholtz wrote a short paper on the conservation of energy, which was one of the very first clear enunciations of the theory, and that paper beyond doubt had a most important effect in shaping and moulding scientific thought subsequently.

Helmholtz, above and beyond any physicist before him or with him, used the animal machine as a subject for study, induction, and deduction. While others dealt with the steam engine, he dealt with man, and accordingly we find that his inventions all took their direction from his bent of thought and specialised work. He wrote two remarkable treatises, one on "Optics" and the other on "Tone," but he dealt with both not from the abstract mathematical point of view only, but from the physiological as well; showing, indeed, the intimate relations which exist between physiological processes and the unalterable truths of mathematics. Thus he it was who first made it clear that the organism had to adapt itself to the laws of light, which it could in no way modify. He was the inventor of the ophthalmoscope, which materially modified ophthalmic surgery, and his studies in acoustics are almost monumental.

Helmholtz was appreciated, and honours were awarded him. The Copley medal of the Royal Society was awarded him in 1873, and in 1883 the German Emperor gave him a title of nobility. The proximate cause of his death was apoplexy. He had a preliminary attack some months ago, from the effects of which he only partially recovered, and he readily succumbed to the second. His temperament was calm, his method of thought wide and precise. He was a man of many friends and few enemies, respecting and respected. Emphatically a great man in the world of science, and one whose name will endure.

## LONDON ASSOCIATION OF FOREMEN ENGINEERS AND DRAUGHTSMEN.

The first meeting of this Association after the recess was held as usual in the Cannon-street Hotel, on Saturday, the 1st inst., at 7 p.m., when the President, Mr. Wm. H. Bale, and the Vice-President, Mr. R. J. Cook, occupied the chairs, and there was a good attendance of members.

After the general business was over, a paper was read by Mr. Jas. J. Pike, on "A Visit to the Scotch Coal Shale Mines." Mr. Pike briefly sketched the rise and progress of the American mineral oil trade from its first annual output of 2000 barrels to the present time, when the production is about 100,000 barrels per day. About the beginning of this period, say, in 1850, when the natural oil was beginning to flow freely from the American wells, Mr. Young, a Scotch chemist, was devising a method of distilling it from coal, and with other gentlemen established works at Bathgate, in the centre of the Torbanehill coalfield, for the manufacture of oil, &c., from cannel coal. Afterwards shale which had been often met with, but was looked upon as a mineral of no value, was used instead of coal, and with so much success that the oil industry developed at a rate almost unparalleled in the history of British manufactures, and although American competition in recent years has contracted it materially, the trade still survives, and is fuller of hope than at any time since 1885. There are at present in Scotland about sixty to seventy paraffin oil works in operation, and as in the case of the gas manufacture, the by-products are of as much if not more value than the oil.

Mr. Pike stated that the shale is found in seams like coal, and described the system of mining and bringing it to the surface, and then described the process of conversion, illustrating his remarks by a large assortment of samples of the various products. The shale is first crushed between rollers, then put into cast iron retorts and distilled at a low heat, somewhere about the melting point of plumbers' solder, when it evolves oil and ammonia vapours, which are collected and condensed separately into crude oil and ammonia water, which latter is converted into sulphate of ammonia and largely used as a valuable manure. The crude oil is re-distilled, washed with oil of vitriol and caustic soda, again distilled, when the lighter portion condenses into crude burning oil and the heavier into a heavy oil containing solid paraffin scale. The scale is cooled, pressed, placed on sloping shelves and heated nearly to the softening point. The softer portion gradually melts out and runs away, carrying with it the colouring matter and leaving nearly pure white wax. The heavy oil, after the hard scale has been extracted, is washed again with vitriol and soda and separated into different qualities of lubricating oils, which after further cooling to remove all the soft scale of low melting point, are finally washed again with chemicals, and so finished. The lighter portion of the crude oil, after several chemical washings and distillations, yields the finished burning oils of different grades.

Mr. Pike stated that the great chemist Liebig once said that it would be esteemed one of the greatest discoveries of the age if anyone could succeed in condensing coal gas into a white, dry, solid, and odourless substance, portable and capable of being placed in a candlestick and burned in a lamp, and it seemed as if this had now been attained in the production of the paraffin wax which is turned out by the ton and made into candles, &c. He also mentioned that it is largely used for preserving eggs, as having a low melting-point they are easily dipped into it, and when cold forms a thin air-tight coating round them which delays decomposition for a considerable time. A vote of thanks was given to Mr. Pike for his interesting description, and the meeting closed,

## RUSTLESS COATINGS FOR IRON AND STEEL.*

By M. P. WOOD, New York City, Member of the Society.

THE protection of iron and steel used in engineering, structural, and art work from the corrosive action of the atmosphere, as well as from air charged with the fumes of many industrial and chemical pursuits, and the fact that the usual coating with paint proves so ineffectual to guard from rapid decay, even when periodically renewed, has long attracted the attention of inventors and experimenters as well as the best efforts of many chemists and scientists. The latter, with all the resources of well-equipped laboratories, have not been much, if any, in advance of the less favoured experimenter who developes his ideas by main strength and awkwardness, though the fact or process once brought to light, the work of the savant is acceptable in proving the *rationale* of the same. Fredric S. Barff, of Kilburn, County of Middlesex, England, and George and A. S. Bower—father and son—of St. Neots, County of Huntingdon, England, were the first to practically coat wrought iron, steel, and cast iron with a magnetic oxide, forming at the cost of the metal itself the protective layer, which is usually formed from paint. This is the process known as the Bower-Barff that was developed in England about the year 1875.†

The process in brief consists of placing the articles to be coated in a muffle heated to approximately 1000 deg. Fah., and when they have attained this heat, either by extraneous firing of the muffle or by passing producer gas or the products of combustion through the muffle and amidst the articles contained, or by both methods named, steam superheated to the temperature of 1000 deg. Fah. is then admitted to the muffle, and the formation of magnetic oxide begins at once. The heat of the muffle decomposes the steam, setting hydrogen free, which can be utilised to assist in maintaining the heat of the muffle, the oxygen uniting with the iron to form $Fe_3O_4$, or magnetic oxide. The period of exposure is from five to twenty hours, according to the size of the articles and depth of coating required, which varies from $\frac{1}{100}$ to $\frac{1}{10}$ of an inch, and can be continued almost indefinitely, or until all moderate thicknesses of iron are resolved wholly into oxide. A very able presentation of the full process was made to this Society in a paper read by Mr. George W. Maynard, and found in "Transactions," American Society Mechanical Engineers, 1884, vol. iv., page 351. The colour of the magnetic oxide so formed is a dull blue-black: the coating is tenacious, though when broken through by drilling, shearing, or mechanical injury, oxidation of the injured surface proceeds more rapidly than in untreated articles.

The high heat and intermittent character of the process is destructive to the retorts or muffles, and the process is necessarily prohibitory to all articles requiring cutting qualities. Its application to fire-arms instead of the customary blueing or browning by acid was not a success, too much attention being required to prevent the springing or distortion of the barrels, and removing the deposit formed in the bore, though it has been employed to some extent in the fittings of fire-arms. Articles distorted in process can be reheated to a low red or black heat and re-straightened without injury to the coating. The process materially weakens the iron or steel articles coated, not only by the amount of material changed from a metal to a metallic oxide or metalloid, but suffers a further loss of strength, particularly in wrought iron, by the burning out of the cinder in articles long exposed to the heat, making what rollers and forgers call "dry iron." A further difficulty appeared in structural work held in place by rivets; the heat necessary to form the oxide caused the loss of set in the rivet. If riveted together after oxidising the parts, the rivet had no protection from corrosion, and Muntz or gun-metal connections became necessary. The coefficient of elasticity between the oxide and the metal from which it is formed, is so nearly the same, that railway bridge members and car truck frames are comparatively unaffected by long periods of service under compression, tension, and vibratory strains. The process applied to the pipes and iron work exposed to the action of mine, sulphurous, or acidulated and sea water, appears to give that protection from rapid decay so long desired by those who "churn" those liquids. The data concerning the cost of application of the process are very unsatisfactory. So much depends upon the size of the articles, depth of coating, whether the furnace or muffle is operated continuously or not; but it must be an expensive process per pound or square foot on account of the skilled labour and superintendence required, setting aside the expense of superheating the steam required to the necessary temperature of 1000 deg. Fah. None of the parties using the process appear to be at all anxious to recommend the adoption of their steam superheating device, or to flit their tales of woe about the same. Costs given range from 5 dols. to 20 dols. per ton of articles treated, but there are many situations in which the protection given by this process would bear an addition to these figures. The amount of steam required if used alone for the oxidising element and for coatings of a moderate thickness, is determined to be: for each pound avoirdupois gain in weight of iron oxidised to form the magnetic oxide, 232·9 cubic feet of hydrogen weighing 2 lb. was set free, making 3 lb. of steam or 75 cubic feet at or slightly above atmospheric pressure.

The above is the theoretical amount needed to furnish the oxygen; in practice from 25 to 33 per cent. more was passed through the superheater and muffle to get results. The deeper the coating the more steam was required. If 1000 square feet of surface was exposed for oxidation only $\frac{1}{64}$in. thick, it equalled 625 lb. of magnetic oxide, and would require at least 2500 lb. or 62,500 cubic feet of steam to be furnished in about six hours, or approximately 17-horse power per hour. The patents for the process, if not expired by limitation or by the non-use requirements of foreign patent laws, are rendered of small value except in special cases, by more recent improvements in the art by several inventors, one of which is a matter of record in this Society; and is of interest aside from its cheap and effective application by not being patented, the inventor by publication having given its use to the public.

The paper No. 180 presented to this Society by Wm. H. Weightman, "Transactions," A.S.M.E., 1886, vol. vi., page 351, embraces a report by Lieut.-Col. A. R. Buffington, Ordnance Department, National Armoury, Springfield, Mass., to the Chief of Ordnance, U.S.A., Washington, D.C., fully describes the process, which is peculiarly applicable to finished surfaces of iron and steel, notably fire-arms and kindred work; the process being conducted at so low a degree of heat as to not affect tempered parts of the arm. Finished surfaces of cast iron are given a bronze-coloured coating which sustains mechanical injury, such as a blow, without cracking the coating or affecting its protective power. The apparatus for armoury work consists of a common cast iron vessel or open-mouthed pot, deep enough to receive the longest piece to be treated—a gun barrel immersed vertically—and large enough in diameter to contain a dozen or more barrels arranged on a movable rack capable of being raised and lowered into the bath of melted nitre, which contains a small percentage of peroxide of manganese. A brick furnace is built around the nitre pot and a coal fire maintains the heat of the mixture, which is hot enough to ignite and maintain combustion in a pinch of sawdust scattered over the surface, or about 650 deg. Fah. The articles polished but not burnished or unduly raised in lustre are simply immersed and moved about in the bath for a given time or until the requisite colour is obtained, which can be ascertained by raising the articles out of the bath and re-immersing them any number of times until the colour is right; then they are removed, cooled in the open air to about the temperature of boiling water, then plunged into hot water to remove the nitre, and then into a sperm oil bath to complete the process. The nitre used must be refined, the commercial article not giving uniform results. Articles not taking the desired colour on the first application, or which bear a streaked or spotted appearance from some peculiarity in the metal, are corrected upon a second application. Care must be taken to prevent the introduction into the bath of water, oil, wood, or any carbon or combustible matter. The nitre mixture is not explosive, even when poured into the open fire, but in this case the arising fumes are suffocating and dangerous. The simple and inexpensive plant, the economy of time, labour, and material, the uniformity of product, and the beautiful colour mark this process an important advance in the art. I have been unable to learn of the application of the process to any large unfinished members of architecture or other structural bodies, but I see no reason why it should not be as effective in these cases as it is in the hundreds of small articles comprising horse furniture and saddlery fittings, general hardware, and articles made of malleable iron, wrought iron, and drop forgings, which are on sale nearly everywhere.

The *Journal* of the Society of Arts has a translation by Mr. Fredric W. North of a paper read before the Paris Société d'Encouragement, by M. Octave de Rochefort-Lucay, on the new Bertrand processes for coating with magnetic oxide, and enamelling iron and iron carburets, and on a new process of tinning for cast iron, that are of interest as being possibly more simple and effective than the Bower-Barff process, and are evidently based upon a new discovery in chemistry which may be thus stated. If a thin adhesive film of another metal is formed on a steel, wrought, or cast iron body, and this article be then heated to 1000 deg. Fah., and exposed to a current of oxidising gas, the oxygen penetrates through the film, oxidises the body metal, and forms magnetic oxide. The formation of this oxide continues indefinitely, the thickness increasing according to the period of exposure to the oxidising current, provided the temperature remains at about 1000 deg. Fah. The film of metal deposited in the first instance disappears in some obscure way, forming oxides which mingle with the magnetic oxide or volatilise according to the nature of the metal of which they are composed. M. Bertrand's experiments to find the best metal for depositing the primary coating led him to select bronze—a mixture of copper and tin—which gave perfect satisfaction, and for depositing it upon the articles to be coated with oxide, he uses electricity or wet baths, and sulphophenolic acid.

The following is the method adopted by M. Bertrand for an oxidation. The article cleansed—which is indispensable—is dipped a few moments in a bath containing a solution of sulphophenate of copper and tin, a slight coating of bronze is formed, the article is immediately washed in cold water and dried with sawdust, then placed in the furnace. Oxide forms, and at the end of fifteen or thirty minutes—according to the size of the article—it is sufficiently oxidised, the coating formed varying from one-tenth to one-fifth of a millimetre for these exposures; longer periods give thicker coating to any desired extent. M. Bertrand uses an electrical current to determine if the coating is of uniform and sufficient thickness. The wires leading from the poles of an ordinary galvanic battery are fitted with a bell arranged to ring when in circuit. If on application of the wires to the article being coated the bell rings, the current passes, showing the oxidation is insufficient; if the bell is silent, the oxide is of sufficient thickness to insulate the object and to practically protect it.

*Process for tinning cast iron.*—The coating of cast iron surfaces with tin is one of the most unsatisfactory processes connected with the mechanical arts. M. Bertrand also uses sulphophenolic acid to obtain a durable coating of tin on cast iron. A bath is formed of water and the acid, in which salts of tin is dissolved in the ratio of 1 per cent. of tin salt and 5 per cent. of the acid. The article to be tinned, previously cleaned, is dipped into this mixture, and is at once covered with an adherent coating of tin, which can be afterwards polished on ordinary buffing wheels of wire and cloth, and a result obtained which is at once cheap and effective.

(*To be continued.*)

---

* Presented at the Montreal meeting, June, 1894, of the American Society of Mechanical Engineers.

† See the United States patents—To Fredric S. Barff, No. 182,148, September 12th, 1876, protecting iron surfaces. Described in the *Official Gazette*, vol. x., page 443. To George and A. S. Bower, No. 234.524, November 16th, 1880, coating iron with oxide. Described in the *Official Gazette*, vol. xviii., page 1147. No. 270,004, January 2nd, 1883, depositing metals upon the surface of iron and steel coated with magnetic oxide. See *Official Gazette*, vol. xxiii., page 440. No. 270,005, same parties, same date, for a furnace used in connection with the process.

---

MORE MIDLAND CATS.—At the engine shed, Buxton, the men make a pet of a fine cat. On August 13th, it being known that the cat had a family somewhere around, search was made. *On the Line* says it was not until Wednesday afternoon that the kittens, five in number, were found in the trailing drag box, directly under the driver's footplate on goods engine No. 915. That day this engine had made a trip to Rowsley and back, thirty-two miles, besides shunting in the yard for several hours. The kittens were dry and warm, and as lively as could be.

DOVER HARBOUR.—After some little delays in the erection of the temporary timber staging at the new harbour at Dover, the first large submarine concrete block was satisfactorily set in position at the East Pier last week. The estimated cost of the East Pier and approach viaduct alone is some half-million sterling, and no doubt, when the whole scheme for the new harbour is completed, something over a million will have been laid out. The engineers for the work are Messrs. Coode and Matthews, the contractor for the whole of the work being Mr. John Jackson, of Westminster.

DEATH OF MR. JAMES TAYLOR.—We regret to announce the death of Mr. James Taylor, of Birkenhead, who was for nearly forty years one of the leading contractors for the Admiralty and other Government Departments. A native of Glasgow, where he was born in 1817, he became connected with Fox, Henderson, and Co, London and Birmingham, and in 1852 established the Britannia Engineering Works at Birkenhead. He was the inventor of the floating graving dock, and the inventor and builder of some of the largest steam cranes in the kingdom. Many of his inventions have been used in Her Majesty's dockyards.

A SUBSTITUTE FOR THE COMPASS.—The "Solarometer," invented by Lieutenant W. H. Beecher, U.S.N., is intended to supplant the compass, especially on iron and steel vessels, on which vessels the compasses would become practically useless if not frequently compared with some standard, owing to the deviation or variation due to the influence of the metal of the ship. Only one of these devices has yet been made—except the models—and this is to be tried on an ocean steamer by permission of the Secretary of the Navy. The instrument is floated in quicksilver contained in a vessel floated in the same material, and this latter vessel is hung in gimbals, so that the instrument will remain practically level in spite of the motion of the ship. A company has been organised to manufacture these instruments for naval and merchant vessels.

LABOUR AND WAGES IN BELGIUM.—THE ENGINEER ought to be accepted as an authority on the subject, and it roundly declares that the prevailing ideas as to the prosperity of the iron trade in Belgium are decided misconceptions. If we look for the fortunes made by individual Belgian ironmasters, it observes, we find that they are few and far between, and in scarcely any case will they compare favourably with those which have been made in this country by such men, for example, as the late Earl Dudley. The great companies do not pay their shareholders any extraordinary dividends. Indeed, taking all the circumstances into consideration, THE ENGINEER is disposed to say that making iron and steel in Belgium is not on the whole so profitable a business as making them in Great Britain. This is a strong statement, no doubt, but there is even more decided evidence on the subject. A representative of the American Government has conducted a comprehensive inquiry into the relative cost of production in the iron and steel trade in different countries. It was proved that the production of a ton of steel costs less in England than either in America—with its boundless iron ore and coal in close proximity, and its natural gas ready to be tapped for its blast furnaces—or in Belgium with its low wages and its long hours.—*Newcastle Leader.*

## RAILWAY MATTERS.

The Rhondda and Swansea Bay line is to be completed in about five weeks.

It is stated that the Russian Government has resolved upon the construction of a railway from Samarcand to the frontier of the Pamir region.

An application has been made to the Mayor of Palermo for a concession for the construction of four tram lines in that town to be worked by electric cars. It is proposed to erect the power station in the Piazza Ucciardone.

The report of the Statistician of the Interstate Commerce Commission for the year ended June 30, 1893, which has just been published, gives the railway mileage of the United States on June 30, 1893, as 176,461 miles. This shows an increase during the year of 4897 miles, being a gain of 2·80 per cent.

The Russian Government has recently received applications from several large foreign manufacturing firms for permission to build workshops in Russia, for the manufacture of rails and locomotives. It is represented that the establishment of foreign factories will obviate the paying, by the railway companies in Russia, of the existing high prices for home material.

The Illinois Central Railroad has been experimenting recently with a device for killing grass and other vegetation on the roadbed by electricity. The electric current was delivered from the generator through the blades of grass to the earth. The rate of movement of the outfit was about five miles an hour. The vegetation that was killed showed signs of distress at once, but it was found that some stalks escaped. On going over the same section a second time the remaining grass was killed, and that which had been killed at the previous passage was fired by the current. The experiments were so far satisfactory that it is probable that a new machine will be designed.

From the returns of Indian railways for the current financial year it appears that from April 1st to July 14th the increase in traffic, as compared with the similar period of last year, is most encouraging. The gross earnings have risen by nearly 34½ lakhs of rupees, and this in spite of a decrease on the Great Indian Peninsular system of close upon 14 lakhs. The East Indian, as usual, heads the list with over 10 lakhs; the Rajputana-Malwa is close on its heels with nearly 9½ lakhs; and the North-Western is a good third with 9¼ lakhs. The Oudh and Rohilkhund line has forged ahead with 5⅓ lakhs; the Eastern Bengal shows a welcome improvement of over 3⅓; and the Bombay-Baroda is 2,40,000 rupees to the good.

The signalmen employed on the passenger and goods stations of the Midland Railway between Millers Dale and New Wells, Derbyshire, have forwarded to Mr. W. L. Mugliston, the traffic superintendent, a petition for a reduction of hours of duty at the busiest boxes. They point out that some of the boxes in the district with fifty trains in twenty-four hours have recently been made second-class with ten hours, whilst on the main lines at the Junction station and intermediate boxes with two hundred trains passing in twenty-four hours still remain third and second-class ten hours. Mr. Mugliston has notified that their memorial is under his consideration. The traffic in this part of Derbyshire has greatly increased since the opening of the Dore and Chinley line.

The tenders for the work in connection with the construction of the Manchester, Sheffield, and Lincolnshire Railway Company's extension from Chesterfield to London have been given as follows:—To Messrs. Logan and Hemmingway, the first twenty miles from Chesterfield towards the south; to Mr. Lovatt, of Wolverhampton, the section from Loughborough to Aylestone, Leicester; and to Messrs. Topham and Co., of London, the section from Aylestone to Rugby; the fourth, between Rugby and Charwelton, is let to Mr. Thomas Oliver, of Horsham, while another London firm has secured the fifth and sixth sections from Charwelton to Brackley, and Brackley to Quainton, the firm being Messrs. J. T. Firbank and Co., of 15, Railway-road, London Bridge. The work will be at once proceeded with, and is expected to be finished in 2½ years. The total length of the railway is 112 miles, and the estimated cost 6½ millions sterling.

On Monday morning two goods trains came into collision outside Knottingley Station about nine o'clock. A Knottingley shunting engine in charge of a number of trucks while proceeding from the station to the depôt, ran into a special butter train on the Hull and Barnsley line, which was approaching on its way to Manchester. While crossing the upper south line to the down north line the butter train caught the trucks of the pilot engine, cutting its way through them, smashing up six wagons and strewing the line with *débris*. The driver and stoker of the butter train stuck to their engine and escaped uninjured, the wheels of the trucks through which their engines passed being piled on the top. The driver and fireman of the Knottingley engine contrived to keep their locomotive clear of the approaching train. Considerable damage was done to the permanent way, as well as to rolling stock, and it was afternoon before the line was again cleared.

The Godhra-Rutlam Line extension to Rutlam has been completed. Of the many extensions of this line which have been proposed, only one is in a somewhat forward state; this is the extension from Rutlam to Ujjain, where the broad gauge would meet the Indian Midland Railway. *Indian Engineering* says there is considerable probability of this extension being made at an early date. The project is now being considered by the Bombay Government, and will shortly go up to the Government of India, on whose behalf Mr. R. J. Bell, the new consulting engineer for State Railways, while in Bombay on his way to Simla, discussed the details of the scheme with the officers of the Bombay, Baroda and Central India Railway Company. That company's large scheme for connecting Bombay with the north without break of gauge is thus likely to be realised in a way. The company's proposals include also the construction of a loop line from Baroda to Godhra, which would shorten the through distance to Bombay by about twenty-five miles. As it is rumoured that the Secretary of State may be disposed to allow some portion of the accumulated cash balances in the Indian treasuries to be expended on remunerative public works, the extensions referred to will probably receive early attention.

While the discussion on the subject of "Light Railways" waxes merry, Mr. A. P. Heywood demonstrates the possibility of their construction in this country, even under the Board of Trade regulations at present existing, by exhibiting a 15in. gauge railway at Duffield Bank, near Derby. The line runs up a gradient varying from 1 in 10 to 1 in 12, about a quarter of a mile long, to a level 80ft. above, where the experimental course is laid out in the shape of a figure 8, so as to admit of continuous runs. This part, somewhat more than half a mile in length, has a level stretch of a quarter of a mile, the remainder consisting of gradients, of which 1 in 25 is the most severe. The minimum curve on the main line is 25ft. radius, but in the sidings some occur as sharp as 15ft. radius. The line is properly equipped with interlocked signals and points on a very simple plan, into the details of which it is hardly necessary to enter. There are on the railway three tunnels, two bridges, and a viaduct 90ft. in length and 20ft. high. At the exhibition two small locomotives, coupled all round, with flexible wheel-base and other improvements, were shown in steam; and closed and open bogie carriages conveyed visitors over the line. Dining and sleeping cars, together with goods wagons, vans, &c., conveying various loads, were shown at work; and also a dynamometer car, fitted with instruments to indicate the power and speed of the engines.

## NOTES AND MEMORANDA.

M. Le Chatelier, who has been making experiments concerning the magnetic properties of Hadfield's manganese steel, finds that the temperature of annealing should be about 1020 deg. Fah., and that from one to two hours suffices to effect the change.

A new photographic telescope with six cameras has recently been completed for the Yale Observatory. One of its applications will be for the purpose of taking six simultaneous photographs of meteors by closing electrical circuits at different points where single telescopes are erected.

The deaths registered last week in thirty-three great towns in England and Wales corresponded to an annual rate of 15·3 per 1000 of their aggregate population, which is estimated at 10,458,442 persons in the middle of this year. Huddersfield and West Ham were lowest with 10·1 and 10 5 respectively, and Liverpool again worst with 24 0.

In London 2369 births and 1175 deaths were registered, 275 births and 255 deaths below the average numbers in the corresponding weeks of the last ten years. The annual death-rate per 1000 from all causes, which had been 17·1, 15·4, and 14·4 in the preceding three weeks, further fell last week to 14·1. In Greater London 3224 births and 1511 deaths were registered.

Out of an area of 768,800 square miles in the French penal colony of New Caledonia there are, according to the report of the Belgian consul at Noumea, 307,500 square miles in which nickel ore is found, and one-tenth of this last-named area has been conceded to mining companies, who are now actively working 7688 square miles. The *American Manufacturer* says the ore occurs in the state of hydrated silicate of nickel and manganese, without the slightest trace of arsenic, and contains from 8 to 10 per cent. of metal, while some samples contain as much as 16 per cent. The mean value of the ore delivered at the port of shipment is about £4 per ton.

In a paper in the *Comptes Rendus* entitled "New Researches on Chromium," by M. Henri Moissan, the author states that chromium has been prepared in large quantity by means of the electric furnace. Pure chromium has the density of 6·92 at 20 deg. C. It is more infusible than platinum, and has, apparently, no action on a magnetic needle. It is practically unacted on in moist air, but burns at 2000 deg. C. in oxygen. It readily combines with silicon and carbon, to form very hard compounds; the silicide scratches the ruby. The pure metal is not nearly so hard, and readily takes a fine polish. It is hardly attacked by acids, resisting aqua regia, and is not acted on by fused potash, though oxidised by fused potassium nitrate, or chlorate.

A new solder for aluminium is being introduced by the Alsite Aluminium Company, 106, Liberty-street, New York. The surfaces to be soldered are cleaned by dipping in a hot solution of soda or potash, then dipped into nitric acid, rinsed in hot water, and dried. Sometimes the surfaces are cleaned by filing the edges to be joined. The parts to be soldered are heated as hot as can safely be done without melting, and a small portion of the solder is spread over the edges by means of a soldering brush, which should be kept heated during the process. The edges are then joined, and more solder is applied and spread evenly over with the brush. During the entire operation the metal is kept as hot as possible, and it is completed when the solder becomes distinctly white or the aluminium assumes a reddish hue.

An essential feature in the employment of aluminium for various industries is the power of that metal to resist the corrosive action of water. *Dingler's Polytechnisches Journal* recently chronicled experiments made on this subject at the Physical Institute of Berlin, which were attended with the following results:—A tube of aluminium was taken, found on analysis to contain ·58 per cent. of silicon and ·32 per cent. of iron, without a trace of lead or copper, also an aluminium plate containing 72 per cent. of silicon, ·50 per cent. of iron, and ·25 per cent. of copper. The experiments showed that aluminium, after immersion for 120 hours in water of varied composition, was corroded, this corrosion being strongest with hot water obtained from the town supply, and least with cold distilled water. The corrosion extended uniformly with the interior of the metal. Brass behaved much better. Although these trials show that the use of aluminium, from a chemical point of view, should only be resorted to under exceptional circumstances, they are none the less instructive with regard to the many other uses to which the new metal can be devoted.

At a recent meeting of the Vienna Academy of Science, Herr Bruno Piesch gave an account of his recent work on the change in the electrical resistance of aqueous solutions, and of the electric polarisation with change of pressure. The author has examined a large number of liquids, both acids and salt solutions. The apparatus—*Nature* says—was so arranged that the resistance and polarisation would be simultaneously measured. The high pressures used were obtained by means of a Cailletet's compression apparatus, and experiments were carried on up to a pressure of 600 atmospheres. The vessel in which the liquid to be experimented upon was placed was enclosed in the iron receptacle of the pump, being insulated by means of an ebonite plug. The following results have been obtained:—A change in pressure is always accompanied by a change in the electrical resistance, the resistance decreasing with increase of pressure. No definite connection is observable between the amount of the pressure change and the concentrate of the solution, but in the case of most of the substances investigated the change was greater in the case of very dilute solutions than in more concentrated ones. The magnitude of the change in resistance with change in pressure is very small, as is also the case with the change in the polarisation. In most cases an increase of the polarisation with increase of pressure was observed, but the irregularities were in this case greater than those observed in the resistance measurements. In conclusion, the author examined a solution of ammonium nitrate in alcohol, when he obtained changes in the same sense as in the case of aqueous solutions.

The photometry of arc lamps is a most unsatisfactory subject, more so, perhaps, even than of most lighting apparatus. Scientific determinations of the candle-power of arc-lamps are now generally made by measuring the mean spherical candle-power; and in instituting comparisons between the candle-power of arc lamps on alternate current circuits and on direct current circuits, to judge from the reports of experts, it is generally considered that this is the only fair method of making the measurement. As a matter of fact, however, so far as the commercial value of the light is concerned, this method is a somewhat misleading one, as in an alternating arc the rays are thrown as much upwards as downwards, and this distribution of light for illuminating a roadway, even where reflectors are used, is not so valuable as the downwardly directed rays from a direct current lamp. *Electrical Plant* says, recent determinations of the candle-power of arc lamps seem to go to prove, also, that there exists an enormous difference between different kinds of arc lamp carbons employed. Measurements of two 450-wall arc lamps, using different kinds of carbons, showed in one case—taking the mean spherical candle-power and employing direct current—only 500 candle-power, and in another, 1200 candle-power Mushrooming carbons with iron and other impurities have, we hope, long been discarded by practical men. It would seem, however, from the above determinations, that a regularity in burning and slow consumption are not only the only things to be thought of, and that carbons ought also to be tested for their illuminating capacity.

## MISCELLANEA.

Kingstown Harbour will shortly be deepened, to enable first-class battleships to anchor at low-water.

The Brighton Town Council have resolved to spend £47,000 in improving the sea front and in protecting the shore from the encroachments of the sea.

The Scarborough Town Council have voted for an expenditure of £70,000 for the construction of a new marine drive and sea wall round the castle foot.

The Mersey Docks and Harbour Board intend to erect a large new shed on the site of the central dockyard, Great Howard-street, supplying it with the requisite hydraulic machinery, roadways.

Messrs. Francis Morton and Co., Liverpool, have contracted for the supply and erection of the whole of the wrought ironwork in the extensive sheds at Hornby Dock, for the Mersey Dock and Harbour Board.

A boiler explosion on the French torpedo boat No. 120 at Toulon has resulted in the deaths of two sailors. An investigation has shown that the accident was caused through a leakage between the boiler and the furnace.

The Local Government Board have sanctioned the loan applied for by the Melton Mowbray Local Board, and approved of the scheme for improvements at the sewage works. The necessary additions include candy tanks, clarifiers, and polarite filters, and the work is to be proceeded with at once.

The Battersea Polytechnic has just issued its prospectus for the second session which opens for day classes on the 17th inst., and for evening classes on the 24th instant. The prospectus offers classes for both men and women in technical science, art, and commercial and general subjects, the number of classes being 133 in 71 different subjects.

The scheme proposed by Mr. J. F. Reade, A.M.I.C.E., London, for the supply of water to Kilkenny, has been selected by the Corporation of that city. Fourteen schemes were submitted, but the names of the other competitors have not been published, as the terms of the competition were strictly secret. It is estimated that the scheme selected will cost £21,500.

At the metallurgical works of Messrs. D. Cattro and Co., Italy, a firm giving constant employment to over 200 hands, although wages have increased by about 10 per cent. in the last three years, the average rates paid per day of 10½ hours are: To boilermakers, 2s. 3d.; ironfounders, 2s. 11d.; riveters, 2s. 11d.; turners, 3s. 2d. This is another striking instance of the lowness of Italian wages.

A correspondent of the *Echo de Paris* reports the invention of another new cuirass or breastplate, this time of hardened leather. It is said to resist absolutely sword and bayonet thrusts, and even a shot from the old-style revolver at 150ft. Another merit is its extreme lightness. A Mr. Lennard, of Brooklyn, has invented a bullet-proof shield, which measures 17in. by 13in., and is 1¾in. in thickness. At a trial of this cuirass held last month at Governor's Island, none of the shots fired succeeded in piercing the shield.

The chrome steel Chase-Gantt armour plate was subjected to a test at Sandy Hook proving grounds on August 24th, in the presence of a number of distinguished visitors. The plate was 5ft. by 6ft. and 10½in. thick, supported against a solid oak backing 36in. thick. The projectiles used were 300 lb. Midvale-Holtzer 8in. calibre. The first shot fired broke the plate in three pieces, some of which were badly cracked. A second shot was fired which broke the top section of the plate in several pieces and went into the sand butt.

Experiments with a new form of torpedo-net cutter are being carried out at the submarine mine station of Bramsnäs by order of the Danish Minister of Marine. The "torpedo scissors," as the appliance is called, are the invention of a Danish naval officer. They are fixed at the head of the torpedo, and their action depends upon its speed. Having effected a breach in the net the scissors fall aside and allow the torpedo to pass on and strike a ship's side. The *Times* says the experiments are so far successful, and the invention is regarded as hopeful.

Much trouble has recently been experienced with the underwater fittings in connection with the auxiliary circulating engine of H.M.S. Æolus, second-class cruiser. The vessel has since been docked at Malta, when it was discovered that the inlet and discharge valves had been fitted the wrong way, and that as a result both spindles were badly bent, and some of the fittings much corroded, while the valves, instead of being water-tight, have been leaking during the whole commission. As this work was done at Devonport, the Admiralty have instructed the officials at that port to ascertain who was responsible for this blunder.

There is to be an electrical exhibition at Ealing which will be opened on Wednesday, October 3rd. There will be, besides the exhibits of leading electrical firms, a loan exhibition, in which will be included many of the latest improvements in electrical science. Almost every known system of telegraphic and telephonic manufacture and manipulation will be shown. There will be delivered during the ten days that the exhibition is open lectures by men of eminence in the scientific world. Sir Frederick Bramwell, for instance, has undertaken to lecture on "Elementary Electricity;" Mr. H. Graham Harris will explain the exhibits and their application to various purposes; and Mr. William Lind will lecture on "Edison and his Inventions." All the public thoroughfares within the district of the Ealing Local Board are to be lighted with electricity. The cost of the installation has been about £30,000.

The following is the report as to the progress of the Manchester Ship Canal works made by Mr. E. Leader Williams, chief engineer of the company, for the half-year ending June 30th, 1894:—"The dredging of the canal to the full depth of 26ft. has been actively carried on and will soon be completed. Eight dredgers have been employed, working day and night. The deposit caused by sewage brought down into the canal by the rivers Irwell and Mersey has materially increased the amount of work to be done. The dock sheds that were in progress early in the year have all been completed. Three additional large three-storey sheds are now being erected, and will be completed this year. A 30-ton crane is now at work, and twenty additional hydraulic cranes are being constructed and will shortly be ready for work. The roads at the docks are in good working order, with the exception of those recently ordered and only now under construction. Good progress has been made with facing the slopes of the canal with stone. The construction of the Walton lock and the dredging of the river Mersey between that point and the Iron and Chemical Works, near Bank Quay, Warrington, are still in progress. The dredging is a troublesome matter, owing to the continued silting. These works had to be carried out in pursuance of clauses inserted in the Act of 1885, to enable large barges from Bank Quay and Warrington to use the Ship Canal during low tides when they could not pass down the river Mersey to Liverpool. The Ship Canal Company will receive a small toll on the cargo in these barges when the work is completed. Notwithstanding the fact that nearly all the steamers using the canal have not previously navigated a similar channel, the trade has been carried on in a satisfactory manner, steamers using the canal regularly by day and night. The hydraulic machinery at the docks, swing aqueduct, bridges, and locks, continue to work in a satisfactory manner."

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

F. G. W. (Helical Gear).—*A letter lies at our office for this correspondent.*

Kernel (Cocoanut Husking Machines).—*Letters lie at our office for this correspondent.*

A. W.—*We are unable to give you the information you require. You might perhaps obtain it by applying to the Chinese Embassy, 49, Portland-place, London, W.*

S. D.—*So far as we can see there is nothing particularly new about your diving apparatus. The use of water-tight sleeves protruded through the side of a diving bell has often been proposed, and, we believe, actually used.*

G. H. T. (Mildura).—*The only illustrated article on colonial pumping engines which appeared in our volumes in 1888 referred to engines made by Messrs. Allen and Co., Lambeth. We cannot call to mind any article which answers to your description.*

S. W. S. (Ampthill).—*The proportions vary with different engines, say about one of oil in 30,000. The temperature of ignition varies with the oil used, and with the same oil it varies with the compression. Ignition tubes are kept at a dull red heat in most cases, but for some oils and in some engines must be kept at a bright red.*

J. C. (Whitehaven).—*It is impossible for us to answer your first question in the absence of all information as to what you know already. As to the second question there are plenty of "grinders" and "coaches" who will give you information by correspondence. But we very much fear that you will not win a Whitworth Scholarship in that way. If you will state your age and give us some idea of what you know now, we shall be in a position to advise you further.*

## SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

| | |
|---|---|
| *Half-yearly (including double number)* .. .. | £0 14s. 6d. |
| *Yearly (including two double numbers)*.. .. | £1 9s. 0d. |

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

| | |
|---|---|
| **Thin Paper Copies—** | |
| *Half-yearly* .. .. .. .. .. .. .. .. .. | £0 18s. 0d. |
| *Yearly* .. .. .. .. .. .. .. .. .. .. | £1 16s. 0d. |
| **Thick Paper Copies—** | |
| *Half-yearly* .. .. .. .. .. .. .. .. .. | £1 0s. 3d. |
| *Yearly* .. .. .. .. .. .. .. .. .. .. | £2 0s. 6d. |

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

## ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

## DEATHS.

On the 30th ult., at Summerseat, near Philadelphia, John Humfrey Osborne, C.E.

On the 9th inst., George Cole Baker, C.E., drowned at Rossbehy, Co. Kerry.

On the 12th inst., in his 78th year, James Taylor, of the Brittannia Engineering Works, Birkenhead.

# THE ENGINEER.

*SEPTEMBER* 14, 1894.

### REPORT ON THE WALTHAM ABBEY EXPLOSION.

The Committee appointed to investigate the circumstances of the explosion at Waltham Abbey have now issued their report. The Committee consisted of Lord Sandhurst, Sir Frederick Abel, Colonel Majendie, and Major-General Lloyd. The chief interest that attaches to the question now is the light that it throws on the manufacture and use of cordite. Before dealing briefly with the report, then, we would point out the bearing and significance of the features brought out. An explosive may be dangerous in two distinctly different ways; it may be unsafe to use or unsafe to manufacture. Clearly the former is by far the more important matter, because danger attendant on the use of an explosive pursues it through its entire life, jeopardises the safety of every person and thing with which it is brought in contact, and the evil becomes aggravated whenever less care than usual is taken. On active service, in tropical climates, and in the hands of inexperienced men, any danger becomes specially formidable. On the other hand, a measure of risk attending manufacture may be grappled with. It is limited in time and confined to a certain spot, and concerns only a particular body of trained workers; nor should there be any liability to the accidents and irregularities that, in the nature of things, must arise on service. The first object, then, with an explosive is that it should be trustworthy and reasonably safe when issued for actual use. Safety in manufacture is quite a secondary question; but one to be duly considered in its place.

Naturally the repeated explosions which have occurred at Waltham Abbey have brought the character of cordite into question. Consisting as it does of nitro-glycerine and gun-cotton, compounds which have each caused death in notable instances, distinct assurance is needed to establish confidence in it. This assurance was obtained at the time of its adoption, and was based on thorough experimental investigation; but the question arises whether accidents, which in the nature of things show mistake or serious fault, upset the conclusions formed. It will be seen from the report before us that the safety of cordite as a fully manufactured article is not only not assailed by any evidence, but, on the contrary, is confirmed. There was a large store of 3000 lb. of cordite drying by hot air in a building only eighty-five yards from the spot where the explosion occurred. This cordite was actually injured by falling *débris* and fragments of the building which was crushed by the explosion, yet none of the cordite was either exploded or ignited, so that in fact it compared very favourably with either gunpowder or gun-cotton. As, then, no cordite was fired at all, and as the only part played by it in the occurrence was to resist explosion under severe trial, we may dismiss the more serious branch of inquiry, and pass on to that only concerned—namely, the danger attending the processes of manufacture of cordite, a question which is certainly a most interesting one to those concerned in the work and those living in the neighbourhood of a cordite factory.

It appears that the explosion took place at 4.8 p.m. on May 7th last, in the washing house and in the "nitro-glycerine store" of the Quinton Hill Factory. These buildings were sixty-one yards apart, and one explosion followed so quickly on the other that there was some difficulty in discovering which took place first. The bulk of evidence, however, went to establish the fact that the washing house was the point where explosion commenced, and that the store followed so rapidly that the effect must be ascribed to the actual shock or air wave of the first explosion. The Committee consider that the second action was far too rapid to be attributed to the effect of falling *débris*, and that there is evidence that the actual flash was not capable of such a result, certain buildings, "nitrating houses," and persons who were actually more exposed to the flash, not suffering from it. The superintendent suggested foul play; but the Committee, while admitting that the buildings were exposed far too much to public approach, cannot find any evidence to justify the idea of foul play. Concluding that the explosion began in the "washing house," it remains to see by what means it might have been brought about, and this, as in similar cases, resolves itself into a surmise as to which of certain unlikely but possible contingencies took place. The explosion was simply a double explosion of nitro-glycerine—that is, of about 1500 lb. in the process of washing, and 2200 lb. of stored nitro-glycerine.

The process of washing is that which has been followed for seven years at least at Nobel's factory at Ardeer. Two lead tanks, 39in. in diameter and 35in. deep, are used. The wash water consisted of a succession of warm soda solutions which were floated on the top of the nitro-glycerine, and ultimately drawn off by a lead skimmer suspended from the ceiling by a pulley and with an india-rubber pipe leading from its bottom to an earthenware tap at the bottom of the tank, the washing being effected by air agitation by means of a lead pipe. Here, then, must be sought the elements of danger. It appears that the soda solution was used at a temperature of 50 deg. Cent.—122 deg. Fah.—which is sufficiently high to render the nitro-glycerine sensitive and reduce the margin of safety in an undesirable way. This was done to facilitate and accelerate the purification of the nitro-glycerine to the rigorous standard required by the Government. Temperatures as high, or even higher, have been maintained in other factories, and the Committee do not think that blame is to be attributed on this account, but they recommend that a lower temperature be maintained in future. This element, then, undoubtedly favoured the explosion, while it could not in itself produce it. The actual provoking cause must be looked for in the handling of the articles mentioned above. The lead skimmer, if dropped on a film of nitro-glycerine on a hard surface, would explode it. It is difficult to see quite how this condition could here be produced, but the skimmer has been known to run down more rapidly than was intended, and if the pulley broke, or some accidental swing struck the skimmer against the side of the tank, an explosion is quite conceivable. Next earthenware cocks have been known to stick, and the application of force might then explode the nitro-glycerine. So the lead pipes and other loose articles might by their fall cause the accident. Further, the precaution necessary to prevent the carriage of grit into the houses on the boots of the men was not as strictly enforced as desirable. Consequently, the Committee see the most probable cause of explosion in the above elements. The accident occurred while the process of washing was in progress, and those engaged were killed, and everything happened, as unfortunately was to be expected, under such conditions that no further evidence is available. While attaching no blame to any of the staff of the factory, the Committee recommend that the buildings be divided and reconstructed in a different way. They consider that the premises and ground at Quinton Hill only afford scope for half the factory now existing; consequently they recommend that duplicate factories be established—one on Quinton Hill and one elsewhere. Further, they suggest that the nitro-glycerine be absorbed into gun-cotton, forming cordite, as fast as it is made, and that no store of nitro-glycerine should be kept. Finally, they recommend that the actual operations should be under the constant and immediate supervision of "a chemist of high standing and of long special experience in these departments of chemical industry." Taking it altogether, it may be said that the report is as satisfactory as could well be under the circumstances.

### LIQUEFACTION IN STEAM CYLINDERS.

Mr. Donkin's able paper read before the British Association and reproduced in our columns, supplies, when taken with correlative facts, an excellent illustration of the difficulties encountered in endeavouring to give shape and coherence to a theory of the steam engine. A correspondent last week asked Mr. Donkin for further information. It is more than doubtful if any one can supply what is wanted. Mr. Donkin has carried out with much care and skill a very elaborate series of experiments. He started with the thesis that the metal with which steam comes in contact at each stroke of the piston liquefies a portion of that steam; and he proceeded to ascertain how much liquefaction took place under various conditions, and what relation the liquefaction bore to the quantity of metal heated. The most important of his deductions, however, is that, by jacketing the cylinder liquefaction is very much diminished, and the economy of steam largely promoted. All this is quite clear, and sufficiently demonstrated. Again, everyone knows that steam is condensed in the jacket, giving up its heat to prevent liquefaction in the cylinder; and it is also pretty well understood that the principal reason why condensation in the jacket is not so wasteful as condensation in the cylinder, is that all the water formed in the cylinder must be re-evaporated therein, while that condensed in the jacket is discharged from it as water. In the first case every pound of water formed in the cylinder is evaporated twice at the expense of the fuel—once in the boiler and once in the cylinder, while steam condensed in the jacket produces water which has only been evaporated once in the boiler. So far all is clear.

The value of a theory lies principally in its capacity for practical use. If the theory does not work in practice it may be interesting, or amusing, or scientific, but its commercial value is necessarily very small. Applying this test to Mr. Donkin's investigations, it is easy to see that their pecuniary value is next to nothing. If they prove anything it is that jacketing is essential to economy in the use of steam. But there are plenty of examples available which prove quite as conclusively that exceedingly economical engines are at work which are not jacketed, and furthermore, that in these engines, turning steam into the jackets did not make them more economical but less so. How can this be? What is the explanation of the fact? There is no satisfactory explanation available, and yet the circumstance is one of value and importance. It affects every theory of the steam engine; it is radical; it goes to the very root of the whole matter. Until a satisfactory explanation is forthcoming there can be no theory of the steam engine framed which is worth the paper on which it is written. We have more than once called attention to the only fact which appears to be able to help in any way to a right conclusion. It is that in all the highly economical engines in which a jacket does no good, there is next to no compression in the cylinder, the leading corner of the diagram being almost a right angle. But this really enlightens us very little, and as we have of course not seen all the diagrams that have been taken from economical unjacketed engines, it is impossible for us to assert that they all have square admission corners. We can only give the results of our own experience; but it is at all events worthy of note that no one has contradicted our statement, or sent us diagrams proving it to be erroneous.

As matters stand at present, we have a very consistent theory of the steam engine, which is that a certain proportion of the steam admitted per stroke is expended in heating up the cylinder in the first instance during the admission period, and is subsequently re-evaporated mainly during the exhaust period, and never does any work whatever on the piston, or, at all events, very little. Mr. Donkin reduces this theory to particulars, and shows how much metal is concerned in doing mischief. There is no question of Mr. Donkin's accuracy; but it is impossible to accept his conclusions as universally applicable to the steam engine, because there are so many steam engines at work, which contradict them. Why do the exceptions exist? This is *the* question to which engineers and physicists should direct their attention. In what direction are we to search for the solution of the problem? The first point to be considered is this: On what does the power of the metal to condense steam depend? Obviously, on its capacity for taking up heat. Can it be shown that two different pieces of cast iron vary in this respect? Has the nature of the surface of the metal any influence? It was suggested not long since in our pages that a surface of metal dead smooth would be a worse absorber of heat than a rough surface. We have made some inquiries on this point, with wholly negative results. In highly economical engines no attempt has been made to polish the insides of cylinder covers or piston faces; indeed, in all cases it is known that these parts soon become dull, and coated with a thin layer of grease and dirt brought over by the steam. On the other hand, Mr. Donkin has proved that by putting plenty of oil into a cylinder condensation is diminished, just as it is by a jacket; and also that a thin coat of varnish has the same effect. The quantity of metal affected and affecting is in any case so very thin that it is nearly, so to speak, all surface, and it would almost appear that it is to some relation between the character of the surface and the steam that we must look ultimately for the solution of the problem; but when we have reached this conclusion we have advanced but a very little way. Then we have the remarkable fact that the efficiency of cylinder metal as a condenser is appallingly phenomenal. It is far superior in this respect to the brass tubes of a surface condenser through which cold water is flowing. Furthermore, it appears to be largely independent of difference in temperature. At all events, whether the range of temperature within a cylinder is large or small, the condensation seems to be about the same. This truth is beginning now to be accepted by those who for years strenuously opposed us when we directed attention to the results obtained in actual practice with triple, compound, and single-cylinder engines.

One point claims further investigation. What is the relation existing between the quality of the steam used and the amount of cylinder condensation? It will be remembered that the late Mr. Willans showed that most disastrous results as regards economy were obtained by permitting a tablespoonful or so of water to remain in a cylinder. It is well known that under certain circumstances pumping engines will not "come indoors" to the full length of the stroke if any water is allowed to remain in the cylinder. The views of Professor Zeuner and his disciples on the effect of water are too familiar to need reproduction here. Now, is it not possible that the key to the anomalies presented by steam engines in practice is to be found in the dryness or wetness of the steam? Is it not possible that much of the water said to enter the cylinder in the form of steam really enters it as water? We commend to our readers, as bearing on the subject, Professor Unwin's most valuable paper on priming which we have recently published. It was time that the subject was handled by a competent unprejudiced authority. We rise from the perusal of the paper with the conviction that a great deal of so-called dry steam is not dry at all, and that the much-vaunted salt test is of no value whatever. Not long since a case came under our notice in which the traps on a row of steam pipes delivered enormous quantities of water. These pipes were very carefully clothed. According to all existing data on the subject, the condensation due to radiation could not have produced one-tenth of the water coming from the traps. It amounted to from 12 to 14 per cent. of the feed-water. Tests were made in the usual way with the balanced water barrel, hose, and thermometer. These over and over again gave 10 to 12 per cent. of water in the steam. Then the salt test was tried, and it showed that the amount of priming was less than a fraction of one per cent. Here we have a case confirming the accuracy of Professor Unwin's conclusions. The first thing, it seems to us, to be done in all engine trials, of whatever kind, is to ascertain the percentage of water entering the engine with the steam. It would also be useful to ascertain the percentage of water in the exhaust steam, on its way to the condenser. As we have repeatedly pointed out, any water received from the boiler as such will find its way to the condenser as water. It will be augmented in quantity by the liquefaction due to the performance of work and to radiation, but the results obtained from the exhaust pipe would serve as a very useful check on those got from the steam pipe.

### A QUESTION OF VALUE.

SOME rather amusing reading is to be found in a printed document where it might be least looked for. The publication to which we refer is a Parliamentary Return just issued, showing the districts in England and Wales in which systems for treating sewage by precipitation are in operation, and stating "whether in such cases the precipitate is of a saleable value." Almost first on the list we meet with Aylesbury, where the sewage is dealt with according to "an expired patent of the Native Guano Company," and where the sludge is sold for a shilling a cartload. When the sewage was treated by the Company, the sludge was dried and ground, and was sold at £3 10s. per ton. Of course, unpressed sludge is nine-tenths water, but the Local Board appear content with a shilling for the sludge, and indisposed to seek the larger sum by the complete A B C process. At Kingston-on-Thames the process is in full working order, the sewage being treated by the Native Guano Company as lessees and contractors under the Corporation. The Company are described as disposing of the treated precipitate on their own account, the material being sold "under the name of native guano, and in the form of a dry powder." The Surbiton Commissioners have arranged "temporarily" for the transfer of their sewage to Kingston, whither that of Hampton Wick also goes, both to be merged in the A B C treatment. The Native Guano Company have fought a brave and prolonged battle on behalf of precipitation, yet the Parliamentary Return now before us lends little support to the idea that a chemical process can extract anything very valuable from sewage. If the Native Guano Company can achieve such a result, it would seem that nobody else can. A general abandonment of hope characterises the reports from the various localities where methods of precipitation have been brought into use. Buxton treats its sewage with "chalybeate water and lime," and passes the sludge through air compressers. Sometimes the farmers cart the product away, and sometimes, being busy, they leave the Local Board to cart it on to their own farm. The Buxton report concludes by saying, with respect to the sludge: "At present, however, it has no saleable value."

At Wolborough, in Devonshire, an alumino-ferric is used, and the sludge is dried in open bays, afterwards selling at half-a-crown per load, "which is about the cost of the forming the bay and drying the sludge." The Prestwich authorities consider "there is a distinct manurial value in the sludge, but hitherto the Board have not sold any." The farmers are good enough to take possession of the stuff, and the Board are willing to let it go. At Melton Mowbray, where lime is employed, the precipitated material "cannot even be given away." What becomes of it we are not told. At Sheffield, the question whether the precipitate from the sewage is of any value meets with the reply: "Not to the Corporation, as they are put to a large expense in disposing of it." At Golcar, it is said: "The Board have not been able to find a purchaser, but there can be no doubt that the product is of some value." In proof that the sludge possesses fertilising properties, it is mentioned that "trees and bushes planted therein have thriven well." At Ealing, in Middlesex, most of the precipitate is used for getting up steam, being burned with the house refuse in the destructor. If we remember rightly, the late General Scott used part of the Ealing sludge for fuel, in order to make cement of the rest. The Finchley report enters rather fully into detail, but acknowledges "there is no sale for the precipitate." It is found to be of some service on heavy land by disintegrating the soil and increasing its porosity, so that the land has absorbed quite 10 per cent. more sewage than before, without in any way affecting the quality of the effluent. At Taunton a sodium process is employed, and there is said to be a "great demand for the sludge in the district, for agricultural purposes." But we are not informed that the Corporation get a single penny in return. All through the list of towns there is the same failure to gain any commercial advantage by the chemical treatment of sewage. Not only so, but the receipts are so ridiculously small, where any are obtained, that the pecuniary result is practically nil. The Native Guano Company may get a price, but it has to spend largely in order to get it, and the system only operates in very few cases. Simpler methods yield an infinitesimal revenue.

The sewage from the district of Polegate, in East Sussex, is treated on what is known as the "Taunton system" of precipitation. The population of Polegate is doubtless small, and so indeed is the receipt from the sale of the precipitate, the sum total in about six years being one pound sterling. At Esher and Ditton, in Surrey, sometimes a little of the precipitate is sold at a shilling per load, but the greater part is "gladly given away." A curious report from Pontefract states that precipitation is effected by "lime and salt water and filtration," and that the product "finds very ready sale;" but the price is not named. Ambleside is happier than Polegate, for it has sold a year's precipitate by tender for £9 5s. But this is only about a penny per head on the population. South Crosland, in Yorkshire, "cannot say" whether the precipitate is worth anything or not. This they know. "No person has been willing to purchase," and the Board are said to be glad to get the article removed without receiving anything "therefor." In the Birmingham, Tame, and Rea drainage district there is partial treatment of the sewage by precipitation with lime in tanks, but the product has no saleable value. Coventry sold 4367 tons of its sewage product for £188 "only," being a little more than 10d. per ton. Stoke-upon-Trent obtained 1s., but there was not a ready sale "even at that price." Lichfield could get little or nothing. Manchester, recently making use of lime and sulphate of alumina, has "not yet had much experience as to the disposal of the precipitate." Salford treats its sewage with a mixture of lime and chemicals, and has many thousand tons of wet sludge, concerning the disposal of which "the Corporation are about to establish a system." Atherton is peculiarly unlucky, having sometimes to bear part of the cost of carting the sludge "in order to induce farmers to take it away." Burnley gets 10d. per ton "after treatment by filter presses and disintegration." Bolton, Blackburn, and Rochdale declare that they find no value in the precipitate obtained from the sewage; Leeds and Bradford announce the same.

While it is evident that the precipitated product of sewage, unless under the auspices of the Native Guano Company, is practically a drug in the market, yet there is some variety in the scale of prices, though the range is limited. Zero obtains in several cases, and something below zero, where money has to be paid to get rid of the "fertiliser." But why should Uxbridge, in Middlesex, get 3s. per ton, and yet be so dissatisfied that "a new system is about to be inaugurated." Hitchin, treating its sewage with sulphate of alumina, gets 2s. 6d. per load. Hereford, by a method not specified, gets the same price. At Leyton, in Essex, the sludge is pressed, which is so much in its favour, yet the Board must needs pay for its removal. Pressing is adopted at Colchester, reducing nearly 18,000 tons of liquid to a little more than 3500; but the average price obtained is only 1s. 6d. per ton, though a return of £260 seems exceptionally good. At Saffron Walden sludge-pressing machinery is employed, but the article produced has hitherto proved unsaleable, though it is thought quite possible that when the product has been tried for a longer period, "some one may consider it worth buying." At Adlington, in Lancashire, the alumino-ferric treatment has been tried, the precipitate selling at 8d. per ton. The system introduced by the International Water and Sewage Precipitation Company is at work in some places, or about to be commenced. At Daventry the sewage is treated by this system, and the results are said to be satisfactory, but the price obtained is only 1s. 6d. per load. The method pursued consists in the use of ferrozine and polarite. But at the root of all the various methods there is this consideration, that sewage has to be treated so as not to be a nuisance; and the pecuniary result, so far as the public are concerned, is altogether a subordinate question. There was a time when sewage was considered capable of yielding a handsome revenue. Irrigation was entered upon with the most sanguine expectations, and precipitation followed suit. But irrigation has its difficulties, though decidedly of service in the raising of certain crops. Precipitation offers a more facile, and a less expensive system, but it is burdened with sludge, and it throws away in the effluent the most valuable of the manurial properties which sewage contains. How to get rid of the sewage at the least cost seems to be the practical question. How to get any money out of it remains an unsolved problem. London is content to let its effluent go into the river, while the sludge is cast into the German Ocean, thus affording the most gigantic example of seeming waste to avoid a greater loss.

◆

### THE CLYDE MEASURED MILE.

THE Clyde "measured mile" at Skelmorlie promises to become more and more the area over which high-speed steamers of all classes, emanating from shipyards all over the kingdom, and even on the Continent, must show their paces and satisfy contractors' stipulations as to speed, turning power, &c. The Naval Construction and Armaments Company of Barrow has just received permission from the Admiralty to run the official trials of the torpedo boat destroyer Sturgeon, launched July 21st, on the Skelmorlie course; while during the past month or six weeks as many as four vessels, built by Messrs. Laird and Company, of Birkenhead—No. 97 first-class torpedo boat; the torpedo cruisers Ferret and Lynx, and the Argentine cruiser Patria—were tested for speed, &c., on the Skelmorlie mile. At Liverpool the measured mile is unsuited for these high-speed vessels; the Lynx, for example, having attained a maximum speed, for some distance, of 27·61 knots. The course at Skelmorlie is well sheltered and exceptionally well suited for securing trustworthy and uniform results. The water is deep—about forty fathoms, and the depth of water, it is generally conceded by experts, should not be less than from ten to fifteen times the draught of the vessel. If less than this the speed will be seriously interfered with. The Admiralty knot at Stokes Bay, from this cause, is almost totally useless for vessels of deep draught or high speed. Attention having been drawn to this subject by Dr. W. H. White at the Institution of Naval Architects two years ago, it is not surprising, therefore, that the Admiralty should readily agree to the trials of vessels built north of the Thames taking place at Skelmorlie, and it may even become the standard testing ground for most of the naval vessels produced in the dockyards of the south. Both the Leopold II., built by Messrs. Denny and Brothers, of Dumbarton, and the Marie Henriette, by the Cockerill Company, now running on the Ostend and Dover route, were tried on the Skelmorlie measured mile, and it is a condition of the contract for a new channel boat now building by the Cockerill Company at Antwerp that it shall try the vessel, when completed, on the Clyde.

### CLYDE SHIPBUILDING.

THE cessation of new orders which has marked the record of Clyde shipbuilding during the past month or five weeks has been agreeably broken in upon—so far, at least, as the artisans of Greenock and Port Glasgow are concerned—by the announcement of fresh orders from the P. and O. Company and others. It has been known for some little time that this enterprising company was in the market for four new steamships, and Messrs. Caird and Co., who have already built very largely for the company, have been entrusted with the building of two of these, the most costly. Messrs. A. Stephen and Son, of Linthouse, and a North of England firm—Messrs. Raylton Dixon and Co., of Middlesbrough—have each received an order to build one of the remaining vessels. The latter are stated to be two passenger and cargo or "intermediate" steamers similar to those on the stocks in Messrs. Caird's yard. The two vessels to be built by the latter firm consist of a first-class passenger steamer of 7500 tons, a duplicate of the Caledonia, also another first-class passenger steamer, 20ft. longer than the Caledonia, which is at present the largest of the company's numerous fleet. This latter vessel, it is also believed, is to be of the twin-screw type. Messrs. Murdoch and Murray, Port Glasgow, who have at present in course of construction three steamers for the Amazon passenger river traffic, have just booked an order for a fourth of similar dimensions.

## LITERATURE.

*The Theory and Practice of Modern Framed Structures.* By J. B. JOHNSON, C. W. BRYAN, and F. E. TURNEAURE. J. Wiley and Sons, New York; and Kegan Paul, Trench, Trübner and Co., London. 1893.

THIS book constitutes the most serious and elaborate attempt yet made and published in the English language to treat completely the subject of bridges, roofs, and kindred structures. It professes to be suitable for the use of students in the technical colleges and of practical engineers as well. In England of late years there has been a veritable flood poured out continuously from our chief publishing sources of so-called technical literature intended to assist in the development of instruction in our new technical schools. To a large extent these schools are misnamed, because their operations are mainly confined to the teaching of very elementary pure science, and venture a very few steps indeed into the domain of real technics. But everything must have an historical beginning, and it may very reasonably be hoped that before another decade has passed, these schools will have so far developed that a commencement to real technical education will have been made.

But this cannot be done generally until the pupils and teachers of these schools have abandoned their present apparent appetite for untruthful and slovenly translations into bad grammar of misunderstood passages culled from the classics of natural philosophy and accepted blindly without personal experimental test and without any effort of mental assimilation except of the most fantastic and careless description. All these must be swept into the rubbish destructor, and for them must be substituted more genuine guides written and taught by men who possess both real knowledge of things and also the power of accurately and clearly imparting their knowledge in intelligible language. There exist already a few such books of the most excellent kind for the use of the advanced students of our technical colleges. The one at present under review is an example of this class. It is written by a combination of men who have experience in what they write about, who are fairly familiar with the experimental facts and with the details of actual professional practice, and who are too well educated in reasoning power and in mathematical facility to be at all blind to the current mistakes in contemporary practice, or afraid to expose them and to recommend improvements deduced by more complete and careful theoretic investigation. It is not intended to assert that the book is without faults, and contains no errors; but it covers a very large range of subject with both theoretical and practical treatment, it goes into a perfectly sufficient amount of detail, and throughout it bears evidence of very honest and laborious endeavour to discover and describe what is true and best. It also proves the authors to possess quite an extensive acquaintance with the special literature in various languages bearing on their subject. Another merit deserves to be noticed—namely, the foot-notes, &c., in which very complete and frank acknowledgments are made of the sources from which theoretic and practical information has been derived.

The book consists of over 500 quarto pages. It is in good print, and is abundantly illustrated by clearly-engraved diagrams. It is divided into two main parts, in accordance with its title. The first part is mainly theoretic; the second mainly descriptive of practice. It is distinctly an American book; the practice described is American, and the theory expounded bears chiefly on American practice. Its distinctive origin is somewhat amusingly illustrated by the extreme brevity of its only allusion to the Forth Bridge, namely, one of half a line's length. In fairness it should be stated that similarly brief reference is made to several important American bridges.

The first ten chapters of Part I. deal with the "historical development" of the truss, general statics of frame structures, roofs, bridges under uniform loads and under wheel loads, conventional loadings used for purposes of design, cross-bracings, beams and girders, struts, and secondary stresses. Then comes a chapter on the statical analysis of suspension bridges; another on swing bridges, two more on cantilever and arch bridges, and the last, or fifteenth chapter, deals with deflections and with the distribution of stresses in redundant structures.

Part II. contains fourteen chapters and three lengthy appendices. These deal with style, choice of site, and the fulfilment of the conditions imposed by site; with fatigue in metals; with general constructive details; details of plate girders, roof trusses, railway and highway bridges, the design of a single-line railway bridge being worked through in full detail; the Howe truss, swing bridges, elevated railroads, æsthetic design, standpipes and tanks; and a chapter on iron and steel mill buildings. The appendices contain examples of detailed specifications, and a description of American methods of erection which will be interesting and instructive reading to those English engineers not already acquainted with these methods.

This statement of the contents shows that the work covers nearly all, if not quite all, the ground indicated by its title. The title-page bears the names of the three leading authors, but the work is really the production of ten different writers. The extensive treatment given to swing bridges is due to Mr. J. W. Schaub, a pupil of C. Shaler Smith. The two lengthy chapters on this subject form an excellent special treatise, but viewed simply as an item in a book upon bridges and roofs generally, they certainly seem to give this part of the whole an altogether undue relative importance. The chapter on æsthetic design, of which more will be said below, is by Mr. D. A. Molitor. It is refreshing to have testimony that the æsthetics of engineering receiving from some Americans that attention which they deserve, and which they do not get in any fair measure in any quarter of the globe.

It might have been advantageous if the first few pages of Chapter I., devoted to elementary explanations, had been written more carefully. Thus the first sentence is ungrammatical; lower down it is stated, somewhat incomprehensibly, that the external forces "are always concentrated or applied at the joints before they can come on the structure as a whole;" also that stress "can only exist in solid or plastic bodies when *unconfined*," and that "the external forces and internal stresses stand in the relation to each other of action and reaction in mechanics." This last statement is made quite generally, not confined to cases of static equilibrium, whereas it is strictly untrue during the oncoming of a load and the consequent generation of vibration, and also during the breakage or collapse of a structure. Again in a work devoted to the use of structural iron and steel, it is surely a superfluous inaccuracy to assert that the limit of constant proportionality between stress and strain is coincident with the limit below which no plasticity appears, *i.e.*, the limit beyond which permanent set begins.

The sketch of the historical development of lattice bridges is meagre in the extreme. The idea given to the reader is, that no one except Palladio, an Italian of the sixteenth century, and certain Americans, ever attempted anything in the way of bridge building. Whether this is intended as a display of American humour, or is meant seriously, it is impossible for an English critic to determine.

Chapter II., dealing with the statistics of equilibrium by the algebraic method, shows less of the above faults; but here again we find it stated that the mechanical conditions of equilibrium "in general fully determine the external forces, provided not more than three are unknown." This is just three times as much as these same conditions are really capable of determining. Each force requires three elements to determine it, and of the nine elements wanted for the full determination of the above three external forces, the conditions of equilibrium supply only three. It is a pity that careless statements of the most important fundamental propositions should appear in a work of this merit and completeness; the more so that it is proved to be mere carelessness in writing by the fact that the immediately following examples display as clearly as possible that it is only three out of the six elements needed to determine the ordinary two supporting forces that can be calculated from the mechanics of equilibrium alone. The glaring inconsistency between the examples and the teaching of the general proposition can hardly fail to confuse the student—if, indeed, it does not lead him to put a lower value upon the book as a whole than it deserves. Again, Example 4 in this place, which is not worked out, sets the student to solve a problem which it is impossible to solve without making as many as three perfectly arbitrary assumptions. It seems inadvisable to encourage students at the very outset to form the habit of solving difficult problems by the easy but often entirely misleading process of assuming this, that, and the other. The same mistake is carried forward into the next chapter, which treats the same subject graphically, where, on pages 23 and 24, it is boldly stated twice over that if the two ends of a structure be fixed to the abutments, the abutment reactions must be parallel, a peculiarly unfortunate error to teach to students.

This part contains, on page 24, a very neat solution of the problem "to draw an equilibrium polygon through three given points." Bow's nomenclature of graphic diagrams is mentioned, although without giving Bow the credit of it; but, unfortunately, it is used very little throughout the book. We notice here and there diagrams borrowed without acknowledgment from Bow and others.

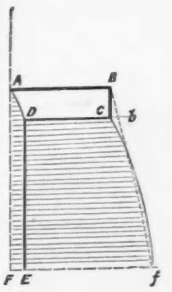
In the next chapter the weight of a roof is estimated as proportional to the square of the span. For railway bridges, in the following chapter, the dead load is taken as the sum of two terms in the first and second power of the span. These rules, although commonly followed, are not at all accurate through any large range of span. It is easy to frame a much more rational formula, which is quite as simple and easy to use. 30 lb. per square foot only is allowed for wind pressure, but on the other hand, on pages 36 and 37, a steep-pitched roof is worked out on the assumption that the *maximum* snow-load is to be *added* to the *maximum* wind-load. In our climate a roof would be cleared of snow by the wind before it rose to hurricane force. We cannot say what would happen in the United States. In Fig. 65 some confusion is produced by the wrong marking of one of the radii of the arch. Several excellent examples of roof stresses are worked out in more or less detail; but we must express our regret that the authors have seen fit throughout the book to give the + sign to compressions, and the − sign to tensions. Since by no conceivable convention is it possible to call the shortening that accompanies compressive stress a positive change of length, or to call the change of length accompanying tension a negative one, it is quite evident that it is inconvenient to adopt the above signs, or rather, the effect is a displeasing want of logical harmony in the nomenclature. Although little practical inconvenience arises, superfluous difficulty is introduced into every theoretical proposition of any considerable generality.

In the two following chapters a careful and able investigation of moments, shears, chord stresses and web stresses, produced by uniform and by rolling wheel loads, is given, the results being explained for a variety of patterns of lattice girder. In considering wheel loads, what are called "influence lines" are extensively and cleverly utilised. These are the invention of Professor G. F. Swain. An "influence line" is a diagram showing the effect produced at one constant section by a passing load of unit magnitude as this load moves from point to point along the bridge. The measure of the effect at the given section produced by the unit load when placed in any position is plotted vertically to scale at this position of the load; and through ordinates thus obtained for all possible positions of the load, the "influence line" or diagram is drawn, the whole of this diagram referring, however, to one particular section. The effect thus plotted may be a bending moment, or a shear, or a stress in one particular bar, &c. This conception is extremely fruitful in useful results, and it is a pity it is not more clearly and simply explained by the author of this part. Many results are obtained, but the obscurity of the method of reasoning leads sometimes to incorrectness in the conclusion, as, for example, in Equation (5), page 76, where a wrong, and, in fact, an unmeaning rule is stated. A capital form of diagram is given on page 85, Fig. 131, to enable the positions to be found for two heavy engines and tenders to give maximum moments and shears.

Chapter VI. is devoted to a discussion of five systems of conventional loading for use in designing, one of which, a new one proposed by the authors, seems to possess considerable advantages over the others.

In discussing the moment strength of beams in Chapter VIII., what is called a "rational formula" for the breaking strength is developed, which no doubt gives a much closer approximation to the real breaking strength than does the ordinary elastic formula. There ought, however, to be now-a-days no risk of the elastic formula being applied without modification to find the breaking strength by any intelligent engineer. Moreover, it ought to be borne in mind more constantly that the calculations of engineers have really seldom anything to do with breaking strengths, but are solely concerned with safe working strengths. For these latter the common elastic formulas for beams are sufficiently accurate. In this chapter again we have to complain of inaccuracy of language. For instance, the author here and elsewhere seems to be haunted by a strange belief that the equations of mechanical equilibrium are applicable only to "*rigid*" bodies. He also says that "within the elastic limit a normal section of a beam which is plane before bending is a plane and nearly normal after bending." Now the actual large variation of shear stress across the section clearly prevents it remaining *plane*, and it also necessarily becomes *not* normal in proportion to the average intensity of shear stress; so that both statements here made are strictly untrue. They are not approximately true because, although the deviations from flatness and normality are small, so also are all other strains considered in the problem, and these deformations are *not* of a minute magnitude compared with the others dealt with. Moreover, it is entirely unnecessary to assume flatness and normality in order to deduce with rigid accuracy the ordinary simple formulas of elastic bending.

The tabular statement of moment quantities contains a very useful column which, although it has been used privately for several decades past, we have not before seen printed in a text-book; the column, namely, of maximum deflections in terms of maximum stresses. The question of variation of shear stress across the section is also more fully treated than is usually seen except in purely scientific treatises. But we cannot agree to the contention that appreciable error is never made by assuming that, in the case of flanged sections, the whole shear load is uniformly distributed over the web section alone, the web receiving no help from the flanges. The numerical example taken to prove this is one of extreme dimensions, the height being 66 times the flange thickness, and the flange width being 32 times the web thickness. "Most economical" values for these ratios can be calculated. This is not done in the book under review, and the above stated ratios are far from being among the most economical. The accompanying diagram shows a very neat and easily drawn, and at same time closely approximative construction showing the variation of shear stress across the section of an equal flanged beam I section. A F and F *f* are centre lines giving the quarter section A B C D E. Set off C $b = \frac{1}{2}$ F E $= \frac{1}{4}$ the web thickness. Draw B *f* straight through *b*. C *f* should be a parabolic arc, which can be well enough approximated to by sketching, and A D is also a parabolic arc, but so nearly straight that a straight line may be drawn for it. The diagram A D C *f* measured from the centre line A F shows the relative variation of shear stress intensity across the section. To the scale of this diagram $\frac{1}{2}$ F E is the average shear stress on the flange, but it must be remembered that this comparatively small stress is exerted over the comparatively large flange section; so that in many cases, at any rate, the flange really bears a very appreciable share of the whole shear load. A rough approximation to this share is a little less than the depth of one flange divided by the depth of the web.



(*To be continued.*)

## BOOKS RECEIVED.

*Department of Science and Art of the Committee of Council on Education, London, S.W., Directory—revised to June,* 1894—*with Regulations for Establishing and Conducting Science and Art Schools and Classes.* London: Printed for her Majesty's Stationery Office by Eyre and Spottiswoode. 1894.

*Stresses in Girder and Roof Trusses for both Dead and Live Loads by Simple Multiplication, with Stress Constants for* 100 *Cases.* For the use of civil and mechanical engineers, architects, and draughtsmen. By F. R. Johnson, Assoc. M. Inst. C.E., civil engineer. Part I., *Girders;* Part II., *Roofs.* London: E. and F. N. Spon. 1894.

*The Water Supply of Towns and the Construction of Waterworks.* A practical treatise for the use of engineers and students of engineering. By W. K. Burton, Assoc. Memb. Inst. C.E. To which is appended a paper on the effects of earthquakes on waterworks. By Prof. John Milne, F.R.S. With numerous plates and other illustrations. London: Crosby Lockwood and Son. 1894.

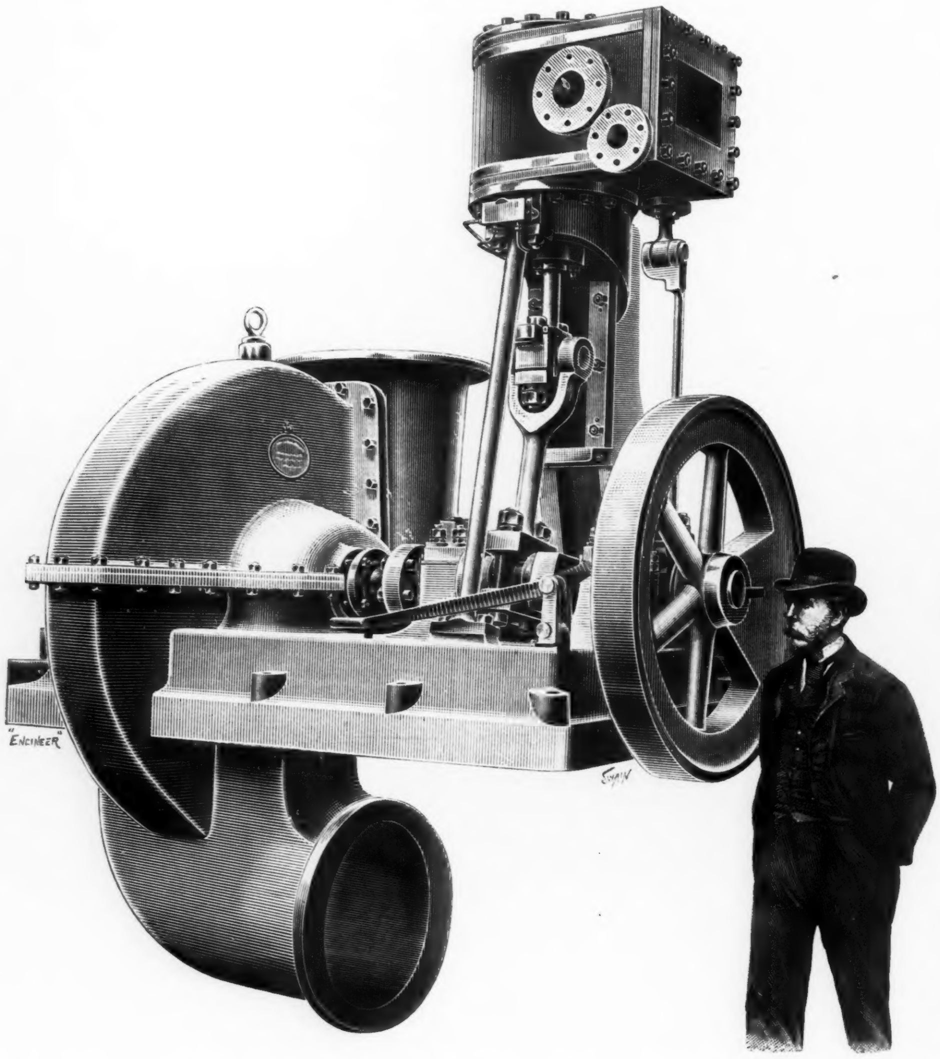
*The Gas, Water, and Electric Lighting Companies' Directory,* 1894. Revised to March 31st, 1894. With a specially written summary of the leading events of the year in the gas, water, and electric-lighting industries, and lists of associations of engineers and managers of gas, water, and electric lighting undertakings in all parts of the world. London: Hazell, Watson, and Viney. 1894.

NAVAL ENGINEER APPOINTMENTS.—Fleet engineers; Peter Colquhoun, to the Achilles, and Edward R. Vine, to the Nile. Engineers: John W. Ham, to the Achilles, and George G. Wright, to the Nile. Acting engineer: Victor de Paris to the Benbow. Assistant-engineers: Alfred T. P. Reed and Arthur Olver, to the Nile. Probationary assistant-engineers: Ernest E. Pethick and Francis Magrath, to the Nile, and G. W. Wooldridge, to the Collingwood.

PROPOSED MEMORIAL TO MR. JOSEPH HALL.—A suggestion has just been put forward that some memorial, either in the shape of a tablet upon the Birmingham Exchange, or some other form of permanent recognition, should be erected to the memory of Mr. Joseph Hall, an early Staffordshire ironmaster of the historic firm of Bradley, Burrows, and Hall, and now deceased some forty years or more. By the invention of the cinder or oxide bottom for puddling furnaces instead of the sand bottom, Mr. Hall is said to have done for iron manufacture what Sir H. Bessemer did for steel. The sand bottom had always been injurious to the making successfully of wrought iron, and the change marked an important era in the improvement of the quality of British iron. Moreover, the invention facilitated the introduction of pig iron made from weaker ores, and thus revolutionised the mixtures of the charges of iron for the puddling process.

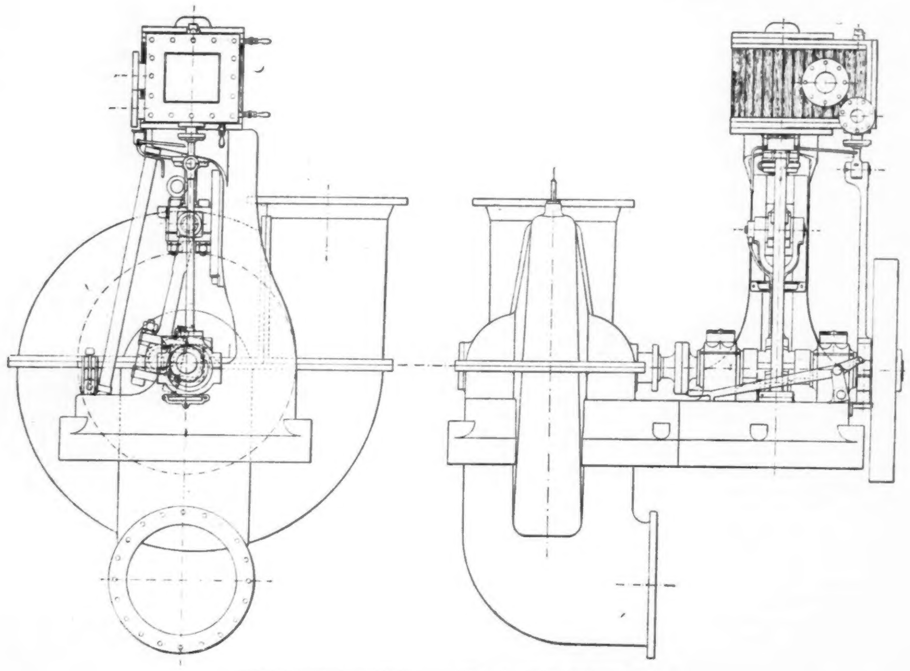
# CIRCULATING PUMPS, P. AND O. S.S. CALEDONIA

MESSRS. GWYNNE AND CO., LONDON, ENGINEERS

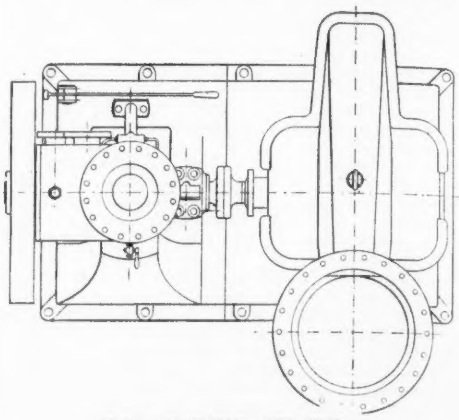


## CENTRIFUGAL CIRCULATING STEAM PUMPS.

Messrs. Gwynne and Co., Brooke-street Works, Holborn, London, E.C., have supplied the circulating centrifugal steam pumps to the Peninsular and Oriental Steamship Company's new vessel Caledonia, built by Messrs. Caird and Co., Greenock. These pumps—one of which is shown in front and side elevation in the accompanying illustrations—are intended for circulating the cooling water through the condensers, and are of large size, having inlet and outlet branches 24in. internal diameter. The pump discs are of gun-metal 4ft. 6in. diameter, keyed on steel spindles cased with gun-metal. The upper portion of the pump casing is made in two parts with flanges for bolting together, with a view to facilitating the removal of the bearings or shaft without disturbing the pipes. The engine cylinder is 15in. diameter by 12in. stroke, has an ordinary D-slide valve, and is bolted to the main casting, the working steam pressure being 170 lb. per square inch. With this pressure, and with a speed of between 180 and 190 revolutions per minute, the output of the plant is 11,000 gallons of water per minute. All the bearings are of special bronze, the working surfaces being of extra large dimensions to minimise wear. The pump bearings are 12in. and 7in. long by 4½in. and 4¾in. diameter respectively; the engine bearings being 10in. long by 4½in. diameter, the crank pin 8in. long by 4¾in. diameter, while that of the crosshead is 6in. by 3in. All the forged parts are of steel, and the construction generally is plain and substantial. The floor space occupied by each unit is 8ft. by 7ft., and the height above the floor 8ft. Special care has been devoted to the continuous automatic lubrication of all parts while the engine is running. A simple barring arrangement is also provided. The engines are made right and left-hand, arranged together compactly on one side of the engine-room. One alone is able to do the work of circulating through the main condenser, the other being a stand-by kept ready for emergency. Each pump and engine weighs about seven tons. They are designed to maintain a vacuum of 28in. when the steamer is going through the hot waters of the Red Sea.



CIRCULATING PUMPS, P. AND O. S.S. CALEDONIA



PLAN OF ENGINE AND PUMP

## THE PENINSULAR AND ORIENTAL STEAMSHIP CALEDONIA.

We illustrate this week the most recent addition to the fleets of the Peninsular and Oriental Steamship Company. We have already given some particulars of this splendid ship in our impression for May 25th of the present year.

She is 486ft. long, 54ft wide, and 37ft. deep, 11,000-horse power, and 7500 tons displacement. She was built and engined by Messrs. Caird and Co., Greenock. She will carry 320 saloon and 150 second cabin passengers, and 1500 tons of cargo. She has a single screw. She will sail on her maiden voyage on October 5th.

## CATALOGUES.

Lumley, Son, and Wood, Limited, West Grove Works, Halifax. Wrought Iron and Steel Welded and Riveted Boilers for Heating Apparatus on the low-pressure hot water, and low-pressure steam systems; Kitchen Range Boilers, Vertical Steam Boilers, and Hot-water Valves. This is a carefully prepared and well executed catalogue of a very large number of different forms and applications of the boilers above mentioned and their applications. The heating power of all the boilers is given in actual quantities of 4in. pipe that they are calculated to heat under average conditions, instead of the maximum quantity which it has been customary to give, based on Hood's rule of 50ft. of pipe for every foot of direct heating surface, from which about 30 per cent. should be made to secure efficiency. The catalogue contains a good index, and useful information on heating. It will be valuable to those who are concerned in the heating of buildings of all kinds.

Lea and Sons, Shrewsbury. Electric Light Fittings. Descriptive and illustrative of artistically designed fittings. This is one of the most artistic catalogues we have ever received. Not only are the designs of the pendants of various forms, and numbers of lights, and the brackets and table lights all of pleasing design, but they are nicely engraved, and every one coloured by hand. Messrs. Lea, Sons, and Co. should have a large demand for their fittings, as they undoubtedly will for this catalogue, although its price accords with the high character of its finish.

Isaac Hill and Son, Derby. Flush Side Cold Sawing Machines for various purposes.

Dewrance and Co., London. Catalogue of Engine and Boiler Fittings, Antifriction Metals, and Bronze. This is a nicely prepared and well executed catalogue of the firm's well-known fittings of various kinds, and illustrations of the application of these metals. It has a very complete index, is bound in cloth, and has the name on the back.

Russell and Co., London. Complete Catalogue of Electrical Engineering Requirements, commencing with steam engines and boilers, combined engines and dynamos, including steam, turbine, and dynamo combinations, machine tools, pumps, fans, &c., worked by electric motors, transformers, accumulators, and electrical fittings generally. A well executed quarto catalogue.

Leeds and London Electrical Engineering Company, Limited, The, Leeds and London. Lowrie-Hall Electric Converter, Station Main Fuse, Converter Fuses, High-pressure Fuse, Station Main Switches, &c.

Leeds Forge Company, Limited, Leeds. Morison Suspension Boiler Furnaces.

Drake and Gorham, Victoria-street, London. Electric Lighting Plant and Accessories.

Fleming, Birkby, and Goodall, Limited, Halifax, Yorks. Belting. A useful catalogue of various kinds of leather and leather link belting, woven beltings, methods of driving, leather ropes for driving of triangular and other sections, cotton driving ropes, belt fasteners and clamps, leather pickers and buffers, shuttles and tongues, canvas and other hose, and rubber mats.

Buchanan and Son, James, Liverpool. Sugar Making Machinery. Brick, Tile, and Pipe Making Machinery, including all the machinery and apparatus necessary for both these industries.

Hayward Tyler and Co., London. Complete Installations for the Electric Lighting of Houses, Factories, Mines, Ships, &c. All fittings amd requisites for electric light work.

Brown and May, Devizes and London. Portable and Semi-portable Steam Engines, High-pressure Undertype Engines, Horizontal, Fixed, and Stationary Engines and Boilers, Pumps, Sluices, Winding Machinery, Gravitation Battery for Wet Crushing and Grinding Mills.

Taylor and Challen, Limited, Birmingham. Shafting, Shaft-fittings, Pulleys, &c.

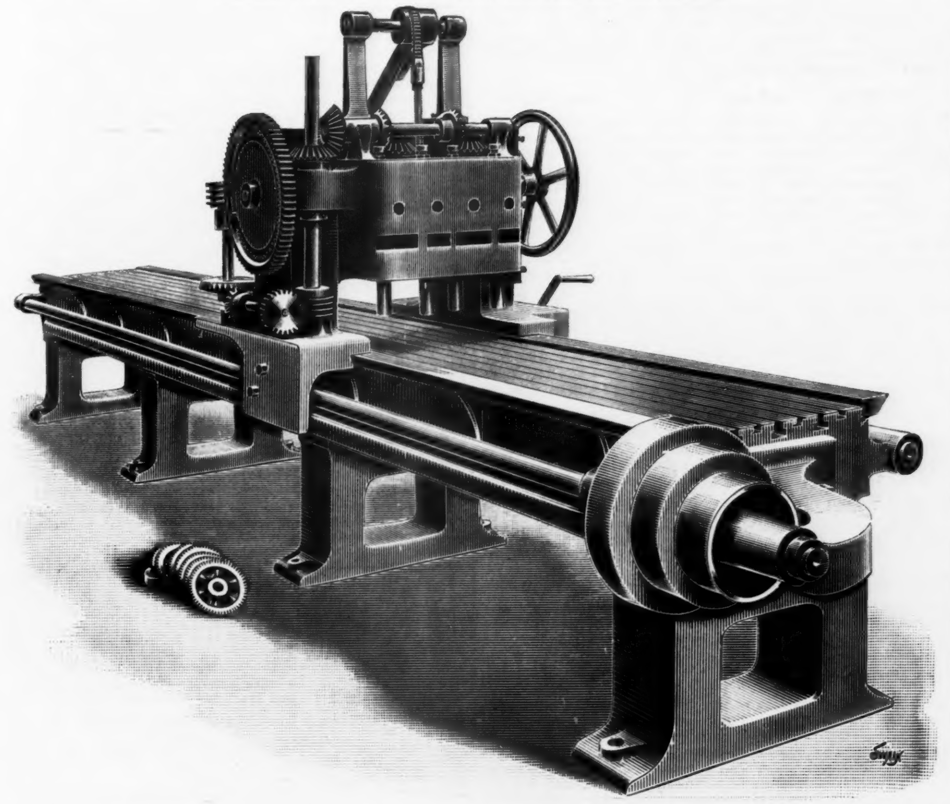
Davies and Son, John, Derby, London, and Cardiff. Mining, Surveying, Engineering, and Mathematical Instruments, Miners' Safety Lamps, Meteorological Instruments, and anemometers.

Cradley Boiler Company, London, and Cradley Heath. Second edition of their second 1894 catalogue of Lancashire, Cornish, Locomotive, Marine and Vertical Type Boilers, Flues, &c.

Ernest Scott and Mountain, Newcastle-on-Tyne. A complete and copiously illustrated catalogue of Electrical Plant and Accessories, Steam Engines, Boilers, Pumping Machinery, &c. Electric Specialities in the shape of Cranes, Capstans, Coal Cutters, Machinery for Electric Welding, &c., all lend to the usefulness of this catalogue.

## MULTIPLE DRILLING MACHINE

MESSRS. CUNLIFFE AND CROOM, MANCHESTER, ENGINEERS



## IMPROVED MULTIPLE DRILLING MACHINE.

WE give an illustration of a four-spindle drilling machine, specially designed and constructed by Messrs. Cunliffe and Croom, of the Broughton Ironworks, Manchester, for drilling spindle rails used in the manufacture of winding frames, in connection with cotton preparation machinery, where it is absolutely necessary that the holes should be drilled exact distances centre to centre, and the rails interchangeable. In this machine, which is of course applicable to many other purposes where accurately pitched holes are required, the drill spindles can be arranged a definite distance centre to centre, as shown in our illustration, or, by the introduction of adjustable quadrant brackets to carry the spindles, the distance can be varied, the driving gear being always in correct pitch in any position of adjustment. The headstock carrying the drill spindles moves in angle bearings vertically, being counterbalanced by a lever and weight, and is provided with self-acting down-feed and automatic disengaging motion to throw out the feed—which is adjustable in any position of the vertical traverse—and return the headstock and drill spindles to the starting position ready for the attendant to traverse the head along the bed for the next series of holes to be drilled. The gear is of sufficient strength to drill four 1in. holes at one operation, and the depth of self-acting feed is variable. The bed is provided with bolt grooves planed from the solid, and also with longitudinal clearance slots to avoid the drill entering and disfiguring the bed after passing through the work when drilling the full depth of the traverse. The illustration shows a machine with a bed 18ft. long to drill four holes at once, 5in. apart centre to centre, transversely in rails up to 15ft. in length—four rails at once—and to clear 20in. between the uprights, to admit and drill rails 8in. deep. The spindles—which never leave their bearings, but descend bodily with the headstock, thus ensuring accurate work—are bored up to receive 1in. taper shank twist drills. The pitch of the holes longitudinally can be varied to anything desired by means of a guide screw, revolving nut, dividing box, and suitable change wheels.

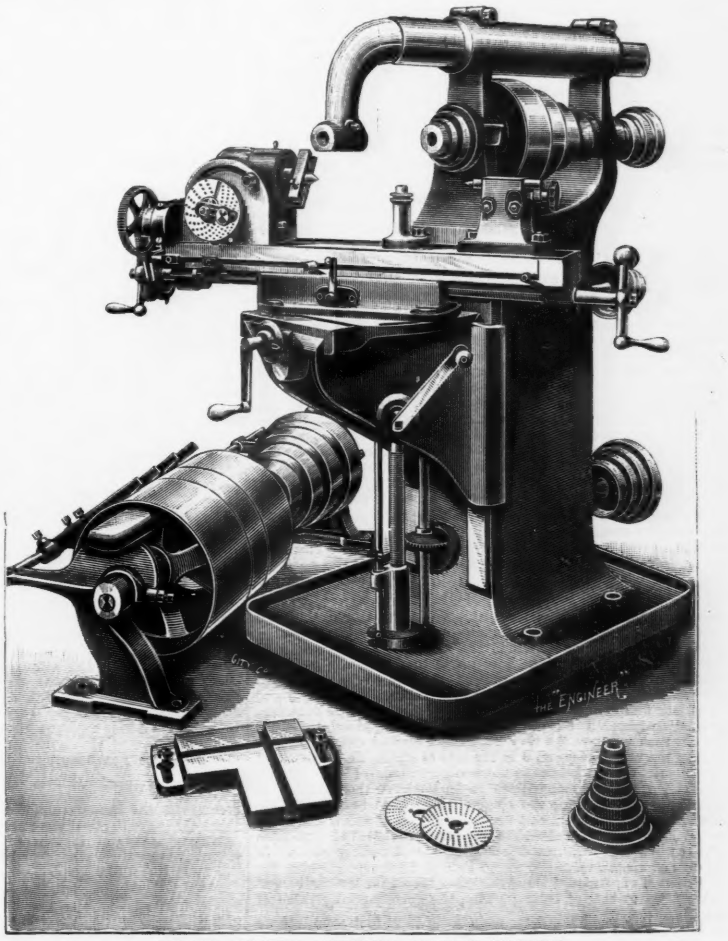
## PROGRESS AT THE CESSNOCK DOCKS, GLASGOW.

THE annual inspection of the harbour of Glasgow by the members of the Clyde Trust took place last week, and in no direction was more satisfaction felt than in connection with the forward state of the Trust's new docks at Cessnock, and the thorough character of the works, in so far as they are completed. Roughly speaking, about three-fourths of the entire undertaking—inaugurated in 1890—have now been accomplished. The scheme, it will be remembered, involves the formation of four basins and a new graving dock, which latter, when finished, will be the largest in the world. The total area occupied by the docks is about seventy-five acres; thirty-five acres being taken up by water space and forty acres by quayage and dry dock. Of the four basins—one an outer canting basin 1100ft. long, and three inner basins, each 1200ft. long—the north basin of the latter group—the basin nearest the river—has been complete for about ten months, and for the greater part of that time has been bringing in a revenue to the Trust. The centre basin will have its quayage complete in about a month's time, and four months subsequently the basin will be dredged out and ready for the reception of shipping. In this way 9000ft. of additional quayage accommodation will be available at the harbour of Glasgow. The quay wall forming the west boundary of the group of basins is now also complete, and sheds are being erected upon it, as well as the foundations for the Trust's new 130-ton crane recently ordered from Messrs. Cowans, Sheldon and Co., of Carlisle. The remaining, or "south," basin has also been begun, and about two years is the period allowed for its completion. The depths of water secured, and being allowed for, in the several basins are likely to be fully adequate to modern requirements either as regards large mail steamers, heavy deadweight carriers, or ships of war. In the completed north basin there is a depth at low water of 20ft., and at high water of 31ft. The centre and south basins are to have a low-water depth of 25ft., and a high-water depth of 36ft. In the outer or canting basin, through which approach is had to the several other basins, the depth is to be as much as 28ft. at low water, and 39ft. at high water, and thus afford ample depth for the clear berthing of the heaviest men-of-war. The several quay walls, which are constructed on the concrete cylinder principle, are founded in sand mostly at a depth of from 55ft. to 58ft. below the cope level. On the top of the concrete cylinders is a superstructure of granite, 20ft. in height, faced with concrete and granolithic. For the working of cranes, capstans, dock gates, &c., a hydraulic power station will be laid down at the east end of the central basin, the contract for the hydraulic machinery involved being in the hands of Messrs. Fullarton, Hodgert and Barclay, of Paisley. Work at the docks has been kept going night and day, the number of men employed being about 600. The plant constantly in use includes four locomotives, twenty steam cranes, ten portable engines of various kinds—for stone breaking, concrete mixing, pumping, &c.—three powerful dredgers, the largest of which has a lifting capacity of 600 tons per hour, and 16 hopper barges employed in conveying the dredged material to Loch Long, the largest of which carries 1200 tons. Since the beginning of operations, two and a-half millions of cubic yards of earth have been dug out, and mostly removed, and it is estimated that three million cubic yards more will have to be dug and removed ere the works are complete. The new graving dock, which is being formed immediately to the south of, and parallel to, the Clyde Trust's present graving docks, is well under way, attention, however, being meantime confined to the entrance end. It is to have a total length of 900ft., a width at the entrance of 83ft., and a depth of water on the sill at high water in spring tides of 27ft. The body of the dock will be 115ft. wide at top, 74ft. wide at bottom, and have a depth of 28ft. from average high-water springs to floor. The length of dock from inside face of caisson will be 880ft., and it is intended to divide this length into two by gates, placed at a suitable point, and with the full width and form of entrance maintained in wake of the masonry at and near the gates. The two present graving docks are only 560ft. and 575ft. in length respectively, and 72ft. and 65ft. across the entrance, with a depth of water of 23ft. The floor of the new dock, being founded on running sand, the laying of a satisfactory foundation is proving a matter of difficulty and painstaking care. To secure a dry bottom for the reception of the concrete, three rows of 9in. fire-clay pipes are laid upon a bed of gravel, and are covered over with a further layer of gravel 1ft. deep. Through the latter the water percolates to the pipes, the joints of which are left open so as to admit the water freely, which then finds its way to the temporary pumps. This was the system adopted with success in the construction of the present adjoining dock, and the concrete foundations being put down after this preparatory process in the case of the new dock promise to be equally successful. The total cost to the Clyde Trustees of the Cessnock Docks works is expected to amount to £1,250,000, which will bring up the total expenditure on the harbour of Glasgow since 1770 to approaching £15,000,000. The constructive and engineering operations at the docks are being carried out by the Clyde Trustees' own workmen, under the able direction of Mr. James Deas, civil engineer to the Trust, and his assistant, Mr. A. Hamilton.

## UNIVERSAL MILLING MACHINE.

THIS machine is an entirely new design, and made from new patterns throughout. The aim has been to embody all the most desirable working features and to make a heavy tool capable of doing the most accurate work as rapidly as possible. It is adapted to a great variety of uses; fluting milling cutters of every description, twist drills, taps and reamers, nut and bolt head finishing, die-sinking, cam cutting, cutting teeth in spur, bevel and worm gears, and automatically cutting spirals.

The column is cast solid with the head and supports for the overhanging arm. It has a flanged base and a cupboard for tools. The spindle is hollow, running in bronze bearings, and is hardened and ground. The outer end is threaded. The bearings are arranged with means for compensation for wear, and are self-oiling. The overhanging arm is in one piece. The table is of extra depth and slides in long bearings. It has a central feed, automatic in both directions and trips at any point. It can be worked automatically at any angle up to 45 deg., and can be operated by hand from either end. The spiral head is designed to be as compact and rigid as possible. It is arranged to take up very little room when being worked in a perpendicular position. Aside from the divisions obtainable through the worm and gears, it has an extra plate on the spindle for indexing directly when fluting taps, twist drills, reamers, &c. The tail stock centre has an angular adjustment. The knee is very stiff and extra strong, and its weight is taken on ball bearings. Its vertical adjustment is operated through a bearing which projects at an angle, so that the traverse and vertical adjustment can be operated simultaneously. Adjustable dials, graduated to $\frac{1}{1000}$in., are provided for both movements.



LUDWIG LOEWE'S UNIVERSAL MILLING MACHINE

The machine is made in four sizes, and is furnished with chuck and vice, set of change gears for cutting different spirals, three index plates, and a double countershaft. In model 1, the table is 33in. long, $6\frac{1}{4}$in. wide, and has a working length of 17in. Adjustment parallel with spindle is $6\frac{3}{4}$in., and vertical adjustment $17\frac{3}{4}$in.; the height of universal centres is $5\frac{5}{16}$in., with a maximum distance of 14⅜in. between them; four grades to cone, $3\frac{5}{16}$in. wide, and weight 1700 lb.

The machine is made by Messrs. Ludwig Loewe and Co., of Berlin, represented in this country by Mr. H. F. Orcutt, of Cannon-street, E.C.

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### VALUES OF $\gamma$ AND J.

Sir,—As my letter on the values of $\gamma$ and J was the *fons et origo* of the lengthy correspondence which has, I think, effectually cleared up the fantastic mysteries of *fin de siècle* thermodynamics, and by so doing conferred an inestimable boon on engineering students, it is the most fitting title to my valedictory contribution to the discussion on thermodynamics. I wish to make a summary of, and advance a few more arguments in favour of, the views I have advocated. I must begin by acknowledging that in my criticism of the law of Boyle and Marriotte I committed the error of mixing together the scale in which equal differences of temperature correspond with equal differences of volume with the scale in which the coefficient of expansion per degree of temperature is constant. In the tables the value of a constant coefficient of expansion is given, which is equal to the total expansion between the thermal states of melting ice and boiling water, divided by the difference between the number of degrees which denote these two temperatures. This coefficient, therefore, only gives the correct expansion per degree of temperature on the Boyle and Marriotte scale at the temperature of melting ice. In the equation $p\,v = a\,(k + t)$ the value of $k$ is constant for all ranges of temperature, and represents the temperature on the Boyle and Marriotte rate of the zero of the scale to which it refers. On a Boyle and Marriotte scale equal increments of volume correspond with equal increments of temperature, so that the value of $a$ is constant. If, therefore, equal increments of volume correspond with equal increments of heat the value of $\gamma$ is constant and the correct equation of relation between the temperatures and pressures is

$$k + t_2 = \left(\frac{p_2}{p_1}\right)^{\frac{\gamma - 1}{\gamma}} (k + t_1)$$

The correct value of the work done in adiabatic compression is also $\frac{p_2\,v_2 - p_1\,v_1}{\gamma - 1}$. If the value of $\gamma$ is not constant these formulas are only approximately true, and the value of $\gamma$ corresponding to the mean between the two temperatures ought to be used. The coefficient of expansion is equal to $\frac{1}{T}$, where $T = k + t$. If the coefficient of expansion per degree of temperature is constant, the equation of relation between pressures, volumes, and temperatures is

$$p\,v = p_0\,v_0\,(1 + a)^t$$

where $v_0$ represents the volume at pressure $p_0$ when $t = 0$. The zero of the scale may refer to any assigned thermal state. If equal increments of heat correspond with equal increments of volume, the value of $\gamma$ on this scale is also constant, and the same as that on the Boyle and Marriotte scale. The equation of relation between the temperatures and pressures is

$$\left(\frac{p_2}{p_1}\right)^{\frac{\gamma - 1}{\gamma}} = e^{(t_2 - t_1)\log.(1 + a)}$$

If the coefficient of expansion per increment of unit of heat is constant, the value of $\gamma$ increases as the temperature increases.

Whether equal increments of volume correspond with equal increments of heat or the coefficient of expansion per increment of unit of heat is constant, can be set at rest by a very simple experiment. The apparatus consists of a receiver fitted with an air-tight piston, which can be moved freely up and down, so as to keep the pressure constant when the temperature of the air in the receiver varies, and a heating apparatus capable of giving out constant quantities of heat per unit of time. If the temperatures of the contained air are carefully noted by an ordinary thermometer graduated with equal intervals, and the times at which the observations are taken carefully noted, the differences between the temperatures will be found to vary very nearly with the differences between the times, if equal increments of heat correspond with equal increments of volume. If they are not found to do so, the temperatures on a scale on which the coefficient of expansion per degree of temperature is constant can be calculated from the observed temperatures, and their differences compared with the differences of the times. Theoretically the differences in the temperatures on a Boyle and Marriotte scale ought to vary exactly as the times, but not exactly on a scale in which the coefficient of expansion is constant, because the specific heat at constant pressure increases as the temperature rises.

The zero of the Boyle and Marriotte scale has nothing to do with the zero of the absolute scale. The zero of the Boyle and Marriotte scale corresponds with the total disappearance of the operative substance of the thermometer. If, therefore, this coincided with the zero of the absolute scale, total deprivation of heat would mean total annihilation of matter, but the mass of a body is unaffected by changes of temperature. Its physical form only suffers change. The difference between the zero of indicated and absolute temperatures must be less than $k$. It has yet to be proved that a body can be totally deprived of heat.

In a former letter I determined the values of J, on the assumption that the specific heat of steam is equal to that of water, by calculating the work done by the expansion of 1 lb. of steam, on the basis that it is equal to the work done in adiabatic compression. For this purpose I used the tabular values of the temperatures, pressures, and volumes of saturated steam, and the value of $\gamma$ from the formula $p\,v^\gamma$ = constant. To justify this method it is necessary to prove that the relations between the temperatures, pressures, and volumes given in the tables agree approximately with the adiabatic relations between them. If it can be shown that when the volume of dry steam is substituted for that of the saturated steam, the absolute pressure, volume, and Boyle and Marriotte temperatures are connected by the adiabatic equations of relation founded on the law of Boyle and Marriotte, it is evident that we have the very best experimental data for determining the values of $\gamma$ and J in the case of steam, since in making the experiments only simultaneous observations of the volume, pressure, and temperature have to be made, without having to make any allowance for the conduction of heat to and from the steam. Air, hydrogen, and probably all gases which obey the law of Boyle and Marriotte have the same coefficient of expansion between the temperatures of melting ice and boiling water. In the case of air the value 460·6 deg. Fah. of $k$ corresponds with the coefficient of expansion ·3654 of the volume from the temperature of melting ice to that of boiling water, the corresponding value of $\frac{p\,v}{t}$ on the Boyle and Marriotte scale being 53·21 foot-pounds if we adopt Regnault's value of $p\,v$ for 1 lb. of air at 32 deg. temperature and 14·7 lb. pressure, viz., 26,214 foot-pounds, for which value the volume of 1 lb. of air at the same temperature and pressure is 12·383 cubic feet. This is the value adopted by Rankine; Maxwell—"Theory of Heat," pages 49, 50—states that this coefficient is probably a little less than ·3665, but probably not less than ·366. Corresponding to ·3665 the value of $k$ is 459·13 deg. Fah., and of $\frac{p\,v}{t}$ is 53·38. If $a$ is the coefficient of expansion per deg. Fah. corresponding to the coefficient ·3665, we have

$$(1 + a)^{180} = \cdot3665 \quad a = \cdot001736.$$

If $t$, $\theta$, represent temperatures indicated by an air thermometer graduated with equal intervals, and an air thermometer in which the coefficient of expansion per degree is constant respectively, and the freezing temperature is in each case indicated by 32 deg., $t$ and $\theta$ will be connected by the equation

$$(1\cdot001736)^{\theta - 32} - 1 = \frac{\cdot3665\,(t - 32)}{180} = \cdot00204\,(t - 32).$$

In calculating the volume of dry steam corresponding to the volume of saturated steam, the coefficient of expansion for dry steam has been taken to be the same as that for air, and the tabular volume of saturated steam at 212 deg. Fah. to be equal to the volume of the same weight of dry steam. It certainly seems reasonable to assume that the weight of the moisture contained in a pound of newly generated steam is independent of the pressure. If this be so the ratio of the volume of the moisture to the combined volume of the moisture and steam must increase as the pressure increases. Thus if R be the ratio for newly generated steam at a pressure of 14·7 lb., its value for steam at 45 lb. will be about 3 R, and at 150 lb. about 10 R. Since the volume of saturated steam at 14·7 lb. pressure is about 1600 times the volume of an equal weight of water, calculations based on the assumption that the tabular volume is equal to the volume of the same weight of dry steam cannot be appreciably affected by the difference between the values. If then $v$ is the volume at 212 deg. Fah., the volume at any other tabular temperature $t$ will be equal to $(1\cdot001736)\,v^{\theta - 212 \text{ deg.}}$ multiplied by 14 7 lb., and divided by the tabular pressure corresponding to $t$. The following table gives the tabular values of the temperatures and volumes corresponding to the pressures 14·7 lb., 45 lb., 150 lb., and 200 lb., and the corresponding values of $\theta$ and of the volumes of dry steam. The values of $\gamma$ from the equations $p\,v^\gamma$ = constant and $k + t_2 = \left(\frac{p_2}{p_1}\right)^{\frac{\gamma-1}{\gamma}} (k + t_1)$, of $k$ from the equation $p\,v = a\,(k + t)$, and of the expression $\frac{p_2\,v_2 - p_1\,v_1}{\gamma - 1}$ given in column I. are calculated from the tabular temperatures, pressures, and volumes of dry steam given in columns I. and II. Those in column II. from the same data in columns II. and III., and those in column III. from the same data in columns III. and IV. The value of $J_1$ is equal to the value of the expression $\frac{p_2\,v_2 - p_1\,v_1}{\gamma-1}$, divided by the difference between the tabular values of the temperature $t_1$ the value of $\gamma$ used being constant and equal to the value at 212 deg., viz , 1·087, so that it is the value of J on a scale graduated with equal intervals, if the specific heat of steam is equal to the specific heat of water, on the assumption that equal increments of heat correspond with equal increments of volume. The value of $J_2$ is equal to the value of the expression $\frac{p_2\,v_2 - p_1\,v_1}{\gamma-1}$, divided by the difference between the value of $\theta$, the value of $\gamma$ used being that in the same column, so that $J_2$ is the value of J on a scale in which the coefficient of expansion per increment of unit of heat is constant. Columns V. and VI. give the values deduced from Mr. Harrison's data.

The calculated volume of dry steam at 45 lb. pressure is about 2½ per cent. greater than that of saturated steam, at 150 lb. about 6½ per cent., and at 200 lb. about 8 per cent. A result which proves that the coefficient of expansion for dry steam is the same as that for air, and that the weight of water in a pound of saturated steam is about the same *cæteris paribus* at all pressures. A very slight alteration in the volume, pressure, and temperature would make the calculated value of $k$ agree with that for air. In calculating the value of $\gamma$, the value $k = 459$ has been used. The values of $\gamma$, calculated from the equations $p\,v^\gamma$ = constant and $t_2 + k = \left(\frac{p_2}{p_1}\right)^{\frac{\gamma - 1}{\gamma}} (t_1 + k)$, are so nearly equal, and the values of $J_1$ so nearly constant, that it is clear that the relations between the tabular pressures and temperatures and the calculated volume of dry steam agree with the adiabatic equations of relation founded on the law of Boyle and Marriotte. I have already pointed out that if equal increments of heat correspond with equal increments of volume, the value of $\gamma$ is constant, both on the scale graduated with equal intervals and the scale in which the coefficient of expansion per degree of temperature is constant, but that it is not in either case if the coefficient of expansion per increment of unit of heat is constant. Corresponding to a rise in the value of $\theta$ from 125 deg. to 126 deg., and of $t$ from 118 deg. to 119 deg., the increment of volume is the same on both scales, and therefore the specific heat and the value of $\gamma$ the same, whether equal increments of heat correspond with equal increments of volume or the coefficient of expansion per increment of unit of heat is constant. If this coefficient is constant the specific heat at constant volume on the Boyle and Marriotte scale decreases as the temperature rises above and increases as the temperature falls below that value. Since the value of $\frac{p\,v}{t}$ is constant therefore the value of $\gamma$ increases as the temperature rises. Although in both scales the value of $\gamma$ rises if equal increments of heat do not correspond with equal increments of volume, as the temperature rises for other thermal states than that represented by the value 124 deg. of $\theta$, the value of $\gamma$ will not be the same on both scales, but within the limits of temperatures selected the difference between the two will not be appreciable. The gradual increase, therefore, in the values of $\gamma$ derived from both the adiabatic formulas proves that equal increments of heat do not correspond with equal increments of volume.

The mean of the four values of $J_2$ is 1132. If the pressures in II., III., and IV. are altered to 44·75, 149·21, and 199·11 lb. respectively, the value of $J_2$ will be equal to about 1132 foot-pounds in each case. The mean value of $J_1$ is 978 foot-pounds. Now the value of $J_1$ is the actual quantity of heat required to raise the temperature of one pound of steam one degree on the scale of Boyle and Marriotte, on the assumption that equal increments of volume correspond with equal increments of heat, and $J_2$ is the actual quantity of heat required to raise the temperature of one pound of dry steam one degree on the constant coefficient scale, if the coefficient of expansion per increment of unit of heat is constant. If, then, the specific heat of steam is less than the specific heat of water, the value of J must be greater than $J_1$ if the first assumption is true, and greater than $J_2$ if the second assumption is true. But the value of $J_1$ is greater than the highest of the values of J obtained by experiments to ascertain the heat required to raise the temperature of one pound of water one degree. If, then, the result of these last experiments is to be relied upon, the specific heat of steam is greater than the specific heat of water. If the results obtained from experiments to determine the specific heat of steam can be relied on to prove that the specific heat of steam is not greater than that of water, and the results of the experiments to determine the specific heat of water that it is not less, it follows that the specific heat of steam must be equal to that of water. The close agreement of the values of $\gamma$ obtained on the assumption that the coefficient of expansion per increment of unit of heat is constant, that the specific heat of steam is equal to the specific heat of water, and that J is equal to 1132 foot-pounds, with the values determined from the adiabatic equations, must be regarded as a proof that the two first assumptions are true, and that the true value of J must be about 1132 foot-pounds. The results of direct experiments like those performed by Joule cannot be relied upon for these reasons. It is necessary to know the exact specific heats of the various substances of which the apparatus is composed, which we do not know, and to allow for heat dispersed into the air, which can only be guessed at. An excessive amount must have been allowed under these heads. In the case of Regnault's experiments to ascertain the temperatures, pressures, and volumes, no allowance of any kind had to be made.

We have now to examine whether the results arrived at in the case of steam are confirmed by dealing in the same way with the data in the case of air. Now the heat required to raise the temperature of 1 lb. of any gas 1 deg. is equal to the work done in adiabatic compression when the temperature is raised 1 deg. If equal increments of heat correspond with equal increments of volume, this is equal to

$$\frac{p_2\,v_2 - p_1\,v_1}{\gamma - 1} = \frac{p_1\,v_1}{t_1\,(\gamma - 1)} \text{ on the Boyle and Marriotte scale,}$$

$$= \frac{p_1\,v_1\,a}{\gamma - 1} \text{ on the constant coefficient scale,}$$

where $v_2\,v_1$ represent the volumes of 1 lb. of the gas at the pressures $p_2\,p_1$, and the temperatures $t_2\,t_1$ on one scale and $\theta_2\,\theta_1$ on the other. If $v$, V, represent the volumes of 1 lb. of air and 1 lb. of steam respectively at the same pressure and at the same temperature on either the Boyle and Marriotte or constant coefficient scale, the ratio $\frac{v}{V}$ is constant for all temperatures so long as the pressure remains constant. If then the specific heat of steam is equal to the specific heat of water, and $S_v$ represents the specific heat of air at constant volume, and $\gamma_a\,\gamma_s$ the values of $\gamma$ in the case of air and steam, we shall have the following equation of relation:—

$$\frac{(\gamma_s - 1)\,v}{(\gamma_a - 1)\,V} = S_v \;.\;.\;.\;.\;.\;.\; (1).$$

Now for the temperature of 212 deg. and pressure 14·7 lb., $v$ = 16 93 cubic feet, V = 26 27 cubic feet. If, therefore, we put $\gamma_s = 1\cdot086$, its value for 212 deg., we get

$$(\gamma_a - 1)\,S_v = \cdot0554 \;.\;.\;.\;.\;.\;.\;.\; (2).$$

Since the difference between the specific heats at constant pressure and constant volume multiplied by J are equal to the work done in expansion by 1 lb. of air when its temperature is raised 1 deg., we have

$$(\gamma_a - 1)\,S_v\,J = \cdot0554\,J = p\,v\,a \text{ on the constant coefficient scale.}$$

$$= \frac{p\,v}{t} \text{ on the Boyle and Marriotte scale.}$$

The following table gives the values of $v$ and of $p\,v\,a$ for the temperatures $\theta$ = 125 deg., for which $\frac{p\,v}{t} = p\,v\,a$ and the temperature 212 deg. and the corresponding value of J in foot-pounds.

| | | | | |
|---|---|---|---|---|
| Temperatures .. .. .. .. .. .. .. .. | 125 deg. | .. | 212 deg. |
| Volume of 1 lb. of air in cubic feet at 14·7 lb. pressure .. .. .. .. .. .. | 14·53 | .. | 16·93 |
| Value of $p\,v\,a$ in foot-pounds .. .. .. .. | 53·38 | .. | 62·2 |
| „ J „ „ .. .. .. .. | 964 | .. | 1123 |

Since the value of J has been determined by the same value of $\gamma_s$ as $J_1$ and $J_2$ in the table for steam, viz , its value at 212 deg., the value of J from this table at the temperature 125 deg. should be equal to that of $J_1$ and at 212 deg. to that of $J_2$. The slight differences are clearly due to errors in experimental data. If we use the value of $\gamma_s$ for steam at 118 deg. tabular temperature, the value of J at 125 deg. should agree with the value of $J_2$. It does so, if we put $\gamma_s = 1\cdot074$. Corresponding to this value we get for the value of $p$, the pressure at 118 deg. from the formula

$$(k + 212°) = \left(\frac{14\,7}{p}\right)^{\frac{\gamma-1}{\gamma}} (k + 118)$$

$p = 1\cdot7$ lb., which agrees with the value in the steam tables. Can any candid man doubt the truth of the conclusions at which I have arrived?

It is stated in the "Encylopædia Metropolitana," that Laplace demonstrated that the ratio of the adiabatic electricity of a perfect gas to its isothermal electricity is equal to the ratio of the specific heat at constant pressure to the specific heat at constant volume, but the demonstration itself is not given. Maxwell—"Theory of Heat," Chapter. IX—attempts to prove that these ratios are equal, but he commits errors identical with those I pointed out in his attempts to prove the truth of the four thermodynamic relations alleged by Clausius to exist, but which do not exist, between the pressure, volume, temperature, and entropy. The error committed in one step is counteracted by another in the next. For the proof of this I must refer your readers to my letter on "The Four Thermodynamic Relations of Clausius," in your issue of June 27th, 1893. That these two ratios are equal may be demonstrated in a very simple way. The elasticity of a given weight of gas is equal to the product of its volume multiplied by an indefinitely small increment of pressure and divided by the corresponding indefinitely small decrement in volume. Let $v$ represent the volume of a given weight of gas subject to the pressure $p$ at any assigned temperature, $\delta p$ an indefinitely small increment of pressure, and $\delta v$ the corresponding indefinitely small decrement in volume. If the changes are isothermal, and we neglect squares and products of $\delta p$ and $\delta v$, we get

$$p\,v=(p+\delta p)(v-\delta v) \qquad \frac{v\,\delta p}{\delta v}=p.$$

If the changes are adiabatic we have

$$p\,v^{\gamma}=(p\,t\,\delta p)(v-\delta v)^{\gamma} \qquad \frac{v\,\delta p}{\delta v}=\gamma\,p\;.\;.\quad (B)$$

We have therefore

$$\frac{\text{Adiabatic elasticity}}{\text{Isothermal elasticity}}=\gamma=\frac{\text{Specific heat at constant pressure}}{\text{Specific heat at constant volume}}.$$

Equation B is only true if $\gamma$ is constant, which it is not, if equal increments of volume do not correspond with equal increments of heat. For indefinitely small changes of volume and pressure its value may, however, be regarded as constant, and therefore this proof of the equality of the ratios for the same temperature of the gas as strictly true. We have then a means of determining a value of $\gamma$ without reference to the specific heats of the gases. Rankine attempted to do so from the approximate formula $v^2=\gamma g h$ for determining the velocity of sound worked out by Laplace, in which Laplace attempted to make allowances for the changes of temperature in the wave of sound, based on the assumption that the value of $\gamma$ is independent of the temperature. The terms and factors which he had to leave out in order to arrive at this simple equation are, however, of such importance that the formula is of no use for determining the values of $\gamma$ from observed velocities of sound; although subject to the assumptions as to the intensity of the sound, &c., on which it is based, it gives values of the velocities approximately equal to the observed velocities. Rankine has, however, given a demonstration of the exactness of this formula, which has received the approval of Maxwell and is given at length in his work on heat, Chapter XV., "On the Propagation of Waves." In a letter published in your correspondence columns, dated May 16th, 1891, I analysed Rankine's demonstration, and proved that it is full of errors. As none of my opponents attempted to find any flaw in my proof of the utter worthlessness of Rankine's demonstrations, I am justified in regarding their silence as an acknowledgment of their inability to do so. Corresponding to Regnault's values of $h$, at 32 deg. and 14·7 lb. pressure, when $g=32{\cdot}2$ft., and the velocity of 1090ft. per second of sound at this temperature, deduced from observed velocities of sound at other temperatures, we get $\gamma=1{\cdot}408$. Rankine adopted this as the constant value of $\gamma$ on the Boyle and Marriotte scale, and with the value 53·21 foot-pounds of $\frac{p\,v}{t}$, we have

$$S_v\,J=\frac{53{\cdot}21}{{\cdot}408}=130{\cdot}4 \text{ foot-pounds, and } S_p\,J=183{\cdot}6 \text{ foot-pounds.}$$

Adopting 772 foot-pounds as the value of J, Rankine obtained $S_p={\cdot}2378$. This calculation was published by Rankine in 1850. The value of the specific heat of air at constant pressure, determined by direct experiments on air by Regnault, and published in 1853, is ·2379—Maxwell's "Theory of Heat," Chapter XI. If in equation (2) we put $\gamma=1{\cdot}408$ we get $S_v={\cdot}1358$, $S_p={\cdot}1912$. Now, in accordance with the assumptions on which Rankine's own calculations are based, equation (2) is stictly true, and therefore Rankine's value of $\gamma$ does not agree with Regnault's value of $S_p$. If we adopt Regnault's value of $S_p$ we have from equation (2) $S_v={\cdot}1825$ $\gamma=1{\cdot}304$. If in equation (1) we put $\gamma_s=1{\cdot}074$ its value for $\theta=125$ deg. we get

$$(\gamma_a-1)\,S_v={\cdot}0472\;.\;.\;.\;.\;.\;.\;.\;.\quad (3)$$

With Regnault's value of $S_p$ we get from this $S_v={\cdot}1907$, $\gamma=1\,243$. As the temperature of the air during Regnault's experiments was probably on an average not very different from 118 deg., this may be regarded as a nearer approximation to Regnault's value of $\gamma$. According to Berard and Laroche $S_p={\cdot}256$, and we get from (3) $S_v={\cdot}2088$, $\gamma=1{\cdot}226$.

Subsequent to the publication of Laplace's formula, Clement and Desormes experimentally determined the ratio of the adiabatic elasticity of the air to its isothermal elasticity to be equal to 1·3492. This result was published in 1819 in the *Journal de Physique*. A full account of the method adopted is given in the "Encyclopædia Metropolitana." The formula velocity for this value is 1064ft., or less than the accepted observed velocity by only 27ft. Laplace, calculating from the experiments of Messrs. Walter and Gay Lussac, subsequently obtained a still nearer approximation to the observed velocity, the difference amounting to less than 10ft. On the results of these experiments, Herschel, the writer of the article, makes the following grave comment—a comment which ought to be read, marked, learned, and inwardly digested by all who may have placed confidence in the "joiner's fits" of the *fin de siècle* scientists: "In inquiries of such delicacy, and where *the effects of minute errors become so much magnified*, it seems hardly candid to desire a more perfect coincidence." As Clement and Desormes' experiments were made to test the approximate truth of Laplace's formula, we shall not be showing any disrespect to those gentlemen in assuming that the value 1·3492 was in their opinion a maximum value. With the lowest value, $\gamma=1{\cdot}243$, deduced from Regnault's value of $S_p$, the calculated velocity is 922ft., sufficiently near to prevent us from concluding that $\gamma=1{\cdot}243$ is wrong. If we put Clement and Desormes' value of $\gamma$ in Equation (3), we get—

$$S\,v={\cdot}1323,\quad S\,p={\cdot}1795.$$

In my criticism of "Student's" letter, which contained a demonstration of the truth of the formula on which Professor Alexander based his demonstration that the scale of the constant pressure air thermometer graduated with equal intervals is the same as Thomson's absolute scale, I simply pointed out that the equation on which he based his proof, $J\,d\,Q=d\,E+d\,W$, is wrong. If heat and work are convertible, the correct equation is—

$$d\,Q=d\,E+d\,W.$$

In accordance with Carnot's theory of heat, the correct equation is

$$\frac{J\,d\,Q\,(T_2-T_1)}{T}=d\,E+d\,W,$$

in which $d\,Q$ represents a quantity of this heat substance, each unit of which at temperature T possesses one J, and $T_2-T_1$ represents the fall in temperature corresponding to the work $d\,E+d\,W$. I have since carefully investigated his demonstration and give you the results, which are well worthy the careful study of all who are called in the jargon of the day technical students. "Student" states that in the mechanical theory of heat we have as characteristic equation of a body $F\,(p\,v\,t)=0$. He next states that we may select any two as independent variables, and selects $v$ and $t$. The first three equations, of which I need quote only one,

$$dQ=\frac{d\,Q}{d\,v}\,.\,d\,v+\frac{d\,Q}{d\,t}\,.\,d\,t$$

affirm that $d\,Q$, $d\,E$, $d\,W$, are each equal to the double of itself. If "Student" had written the equation $J\,d\,Q=d\,E+d\,W$, in the form

$$J\,Q=E+W \qquad (1)$$

he would have escaped making an egregious blunder, and could have obtained at once by differentiation the equations

$$J\,\frac{d\,Q}{d}=\frac{d\,E}{d\,v}+\frac{d\,W}{d\,v} \qquad (2)$$

$$J\,\frac{d\,Q}{d}=\frac{d\,E}{d\,T}+\frac{d\,W}{d\,t} \qquad (3)$$

By differentiating (2) with respect to $t$, and (3) with respect to $v$ and subtracting, "Student" arrives at the following equation:—

$$J\left\{\left(\frac{d}{d\,t}\right)_v\left(\frac{d\,Q}{d\,v}\right)_t-\left(\frac{d}{d\,v}\right)_t\left(\frac{d\,Q}{d\,t}\right)_v\right\}=\left(\frac{d}{d\,t}\right)_v\left(\frac{d\,W}{d\,v}\right)_t-\left(\frac{d}{d\,v}\right)_t\left(\frac{d\,W}{d\,t}\right)_v \qquad (4)$$

"Student" then puts $d\,W=p\,d\,v$ and arrives at the equation—

$$J\left\{\left(\frac{d}{d\,t}\right)_v\cdot\left(\frac{d\,Q}{a\,c}\right)_t-\left(\frac{d}{d\,v}\right)_t\cdot\left(\frac{d\,Q}{d\,t}\right)_v\right\}=\left(\frac{d\,p}{d\,t}\right)_v \qquad (5)$$

which is supposed to be identical with the equation.

$$J\left\{\left(\frac{d\,M}{d\,t}\right)-\left(\frac{d\,N}{d\,v}\right)_t\right\}=\left(\frac{d\,p}{d\,t}\right)_v \qquad (6)$$

accepted by Professor Alexander and believed by him to be accepted by all scientists as true. If N, the specific heat at constant volume is independent of the temperature, $\frac{d\,Q}{d\,t}=N$, but otherwise not. If therefore $\frac{dQ}{d\,t}=N$ we have $\frac{d\,N}{d\,v}=0$. If M is the heat absorbed per increment of unit of volume by unit of mass during isothermal expansion, $\frac{d\,Q}{d\,v}$ is not equal to M, because the so-called latent heat of expansion does not vary as the increment of volume. M, $d\,Q$, and $d\,v$ are connected by the equation

$$d\,Q=\frac{M\,[\log.\,(v+\delta v)-\log.\,v]}{\log.\,(v+1)-\log.\,v}$$

Since Q may be represented by the product $p\,v$, $\frac{dQ}{d\,v}=p+v\,\frac{d\,p}{d\,v}$ and therefore $\frac{d\,Q}{d\,v}$ represents a pressure, not a quantity of heat. Now "Student" obtained equation (4) by putting $\left(\frac{d}{d\,t}\right)_v\left(\frac{d\,E}{d\,v}\right)_t=\left(\frac{d}{d\,v}\right)_t\left(\frac{d\,E}{d\,t}\right)_v$ which is quite right, but how is it that "Student" has overlooked the fact that the same differential coefficients of Q and W are also respectively equal to each other? If we put $d\,W=p\,d\,v$, the first term of the right-hand member of equation (4) is equal to $\left(\frac{d\,p}{d\,t}\right)_v$, but it is beyond my capacity to differentiate $d\,v\,\frac{d\,p}{d\,t}$ with reference to $v$. If "Student" had put $W=p\,v$, he would have found that the right-hand member of equation (4) is equal to zero. Equation (4) is of the form $0=0$.

I have demonstrated that the equations of relation alleged by Clausius to exist between the temperature, pressure, volume, and entropy do not exist; that in fact, whether the zero of the Boyle and Marriotte scale does or does not refer to the same thermal state as the zero of the absolute scale, entropy has nothing to do with the thermal state of the body, and therefore nothing to do with the science of thermodynamics; that the second law of Clausian thermodynamics is not true, and that the formula—which is evidently regarded by Professor Alexander, and all fashionable *fin de siècle* thermodynamicians as one of the groundworks of the science—is not only based on a false assumption, but is arrived at by calculations full of errors of analysis. What more is needed to prove the utter falsity of the whole system of *fin de siècle* thermodynamics?

When I adopted the profession of engineer, I at once commenced to study Rankine's "Applied Mechanics" and "Prime Movers." I found, however, that I could not make head or tail of either; and, as I found at the same time the contents were not likely to be of much use in my profession, I threw the books aside. Having subsequently to carry out an installation of turbines, I again tackled the subject of water power, and soon found the reason why I could not understand one section of Rankine's work on "Prime Movers," the validity of which has been admitted by Professor Alexander. About eight years ago it became necessary for me to thoroughly investigate the question of transmission of power by compressed air and high-pressure water; and, in the course of my study calculated the value of J by means of the adiabatic formula and experimental data in the case of air. The result obtained was within a few decimals of a foot-pound equal to 772 foot-pounds, the hitherto accepted value of J. This result would not have been obtained if all the data had been arrived at by independent experiment, but it was not till some time after that I found out that the value of the specific heat of air at constant volume had been calculated from Regnault's value of the specific heat of air at constant pressure by means of the value 772 foot-pounds of J!! This discovery caused me again to study the question of heat, and to try to get at the root of *fin de siècle* thermodynamics. This time I took up Maxwell's work on heat. To my surprise I found therein the same difficulty that I had found in the case of Rankine's works. I could not understand Maxwell. After repeated attempts to overcome the difficulty I met with, especially on the subject of entropy, persevered in from belief that the University of Cambridge would not lend the sanction of her authority to a work full of errors, in what may be regarded as mere matters of analysis, however patronising or tolerant she may deem it advisable to be of the advocacy of fantastic untenable theories, I came to the conclusion that Maxwell must be wrong, and set about finding out the errors. The result of my investigations have already been published in your correspondence columns. Your readers must judge for themselves the measure of the success I have obtained by adopting this method of getting to understand *fin de siècle* scientist writings. It is abundantly clear that the passing of examinations with glowing honours affords no proof that the successful examinees understand the subjects in which they have been examined. Such could not be the case if the examiners themselves were masters of the subjects in which they have to examine. The modern system of education is rotten from its rind to it core. It has been developed by teachers, who have utterly ignored the only sound principles of education. *Non multa, sed multum. Non omnes omnia possumus.*

During an epoch of crazes in scientific and literary life, which happily appears to have reached its climax and to be on the wane, of geniuses in research and hunters of all types after ephemeral notoriety, the quickest and easiest way to achieve success has been proved to be, to write either catching trivialities or oracular absurdities, which neither the writers themselves nor anybody else can understand. Some writers have the faculty of describing correctly, parrot fashion, scientific processes, which they are themselves quite incapable of understanding. For a period of more than forty years, poor Bacon's spirit must have suffered tortures at the outset unspeakable, and of ever increasing intensity. Star-eyed science indeed! How copiously during all those years must the grove of Academus have been watered with the tears of its nymphs.

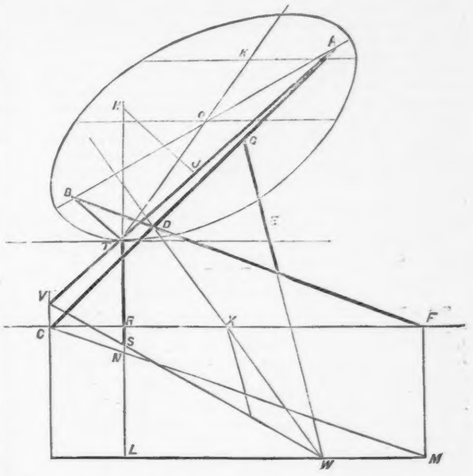
## THE GRAPHIC STATICS OF A DECK CHAIR.

SIR,—By a very curious coincidence I have this week been working out for my own amusement the very interesting problem which "Canvas Back" propounds for your readers' benefit. The solution I arrived at is as follows:—It is first necessary to know the directions along which the forces exerted by the canvas on the cross-pieces act. These would be easily found by graphic construction if (1) we knew the precise distribution of pressure on the canvas; (2) we could be sure that the whole weight of the sitter came on the canvas. Neither of these conditions, however, can in practice be fulfilled. With regard to (2) it is obvious that a considerable and variable portion of the weight is taken directly by the bar B, and is not transmitted by the canvas at all; also that the pressure of the sitter's feet on the ground cannot possibly be estimated. Without further data, therefore, the problem is quite indeterminate. In order to arrive at any definite result it is therefore necessary to make some assumptions with regard to the distribution of the weight.

If the whole of the sitter's weight is taken by the canvas it is obvious that the resultant of the two end-tensions must be vertical, and that therefore given their directions and their resultant—*i.e.*, the weight of the man—they can be completely determined by the parallelogram method, and this quite independently of variations of local pressure on the canvas. These latter are integrated, as it were, by the canvas, and are completely taken account of by the direction which the ends of the canvas take up. If, therefore, we are given these directions, we have all we require, and can find the line of action of the weight on the chair.

The simplest assumption of all is to imagine that the sitter is a very good business man, that is to say, he must be very acute and very slippery, so that he may be replaced by a very small roller of his own weight placed transversely on the canvas. It remains to determine graphically the position taken up by the "acute" portion or roller. This is shown in the diagram. Describe an ellipse with foci A and B, whose major axis = length of canvas. Draw a horizontal tangent at T, and determine the precise point of contact by means of the conjugate diameter K O T. T B and T A are then equally inclined to the vertical T R through the point T. (The *rationale* of this construction will be obvious to anyone who knows the elements of co-ordinate geometry.) T will therefore be the position taken up by the roller. Of course the two tensions T B T A must be equal, since our sitter is slippery. These tensions can be found by setting off T H = 160 units, and drawing H J parallel to B T. T J is then the tension in the canvas.



The pressures at C and F must now be found. This may be done by setting off R L = 160, and completing the parallelogram C M as shown. R N is then the pressure at F, and N L that at C. All the remaining stresses, *i.e.*, the shear at D and the compression in E, may now be found in one operation, *i.e.*, by considering the equilibrium of either the piece B D F or A D C. Both give the same result, as may be proved.

It is now to be noted that the strut E can only exert a definite force in the direction of its length, and that the pin D can only exert a "force of constraint" in a definite direction at present unknown. We have therefore the body A D C acted on by four forces—(i.) The tension along A T known in magnitude and direction; (ii.) an upward force at C likewise completely known; (iii.) a force along E G whose direction is known; (iv.) an unknown force through D. Of these (i.) and (ii.) being produced meet in V and have a resultant = S V in magnitude and direction. We know, therefore, since the body is in equilibrium, that the resultant of S V and the force along E must pass through the point D. These forces meet in W. The resultant, *i.e.*, the upward pressure on D, is in direction W D and of magnitude W X.

This completely determines all the doubtful stresses. The bending moments, &c., in the members can easily be found by applying the ordinary rules.

ARTHUR H. BARKER.

Norwood, Pontefract, September 7th.

SIR,—In the ingenious problem set by "Canvas Back," a great difficulty is introduced by supposing a person to sit in the chair. He will assume various positions. To simplify matters I suggest that instead of a man we suppose that a small cask, say a foot in diameter, be placed in the chair.

I have been working at the question, but I am puzzled to find that there is no vertical component of the load at the forward end of the canvas. In a chair in which I have tried the experiment, I find that the pull of the canvas lifts the front end of the seat up, tending to cause it to turn round A in the direction of the arrow. How is this to be dealt with?

## THE THEORY OF THE STEAM ENGINE.

SIR,—With reference to Mr. Maurice Cross's letter in your last issue, his remarks as to a supposed difference between saturated steam and other gases in their behaviour under free expansion are either obscure or absolutely invalid. A comparison of the behaviour of saturated steam and air when near its point of liquefaction has, so far as I am aware, never been attempted, and it is at this point that the comparison must be made, if it is to have any direct force.

As a matter of fact, we know that the temperature of saturated steam is not lowered below that corresponding to its terminal pressure after free expansion. On the contrary, steam is superheated by free expansion—that is, expansion taking place absolutely without the performance of external work. The free expansion of ordinary nearly perfectly gaseous air results in the lowering of the temperature—small in amount, but still sufficient to be clearly obvious when a proper amount of experimental skill and knowledge are brought to bear in carrying out the operation. Joule and Thompson's experiments in this direction are now historical and quite conclusive.

On those experiments I based the statement I made in your columns some years back, that "the energy of a pound of air is slightly increased by a reduction of pressure, provided its temperature remain unaltered." For this statement I was assailed by several of your correspondents, notably Dr. Lodge—*ex cathedrâ*, as usual. He, however, was finally compelled to admit, somewhat ungraciously, the accuracy of my statements. Experiments on air at ordinary temperatures and pressures, however, are not to be taken as applying to air when so near its point of liquefaction as is saturated steam. Henry Cherry.

21, Festing-road, Putney, S.W., September 11th.

Sir,—Mr. Donkin in his most interesting paper does not appear to have worked out any law of condensation in relation to the difference in temperature between the cylinder and the steam. May I ask him if he thinks that such a law exists and can be worked out? Thus, for example, will the condensation per square foot of surface be greater in the high than in the low-pressure cylinder of a triple-expansion engine? J. P.

Doncaster, September 11th.

### TRADE MARKS IN GERMANY.

Sir,—It may interest your readers to know that a new German Trade Mark Law comes into operation on October 1st next. According to the present law British marks are registered at Leipzig, but under the new law all previously recorded marks must be entered on the Imperial Register at Berlin. The sooner this is done the better, as the first applicant secures priority, and marks previously registered at Leipzig, unless re-registered, will be disregarded by the Berlin officials when dealing with new applications. Owners of trade marks entered on the Imperial Register will be officially informed of any applications for similar marks for the same goods. Infringers of registered marks will be liable to fine and imprisonment, and also to pay an indemnity to the registered proprietor.

Any further information respecting the above can be supplied by this office. Reginald W. Barker, F.I. Inst. F.S P.A.

British Trade Protection Office, Monument-chambers, E.C.
September 7th.

### HOUSE COAL IN LONDON.

Sir,—The following figures may interest many of your readers:—Good to best house coal at the pits, 11s. to 13s. 6d.; railway to London, north of the Thames, 8s. 9d. per ton; railway to London, south of the Thames, 10s. 3d. per ton; wagon hire, 1s. per ton, north or south; total cost of a ton of coal, 20 cwt., in the truck at the coal merchant's siding, best coal, North London, 23s. 3d. per ton; South London, 24s. 9d. There is little or no profit on this class of coal. The competition among coal merchants is now very keen, and if it were not that they can make favourable contracts, and get the long ton of 22 cwt., they could not make a living. Seaborne coal is nominally much cheaper, but there is 30 to 40 per cent. of small, which keeps it level with railway carriage. If the breakage could be reduced, the price of coal in London would fall. A Consumer.

Clapham, September 11th.

### FORTIFYING PORTSMOUTH.

Sir,—My excuse for troubling you is my country's need, and sometimes simple ideas are overlooked. There is a scheme for fortifying Portsmouth. I think that the best plan may be to build on each side of the fairway towers, with engines in them; so that cables may be hung across the fairway and stretched or lowered, as the case may require. The engines could light the towers.

Gong Gong, Ballarat, Victoria, Australia. John Liddes.
August 4th.

### ALUMINIUM BOATS.

Sir,—Seeing an account of aluminium boats in your issue for 7th inst., where allusion is made to one exhibited recently at the Grafton Gallery, perhaps I may be allowed to point out that the framework was made by this company, and that Messrs. Swain and Kirby, who are represented as being the makers, merely covered it with aluminium for the Berthon Boat Co., Ltd.

Romsey, Sept. 11th. E. P. Berthon, Manager.

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*Tramcar fenders.*—The increased speed of street cars, due to the widely increasing use of cable and electric motive power, has led to so many accidents that numerous devices are being tried to prevent people when struck from falling under the car and being run over. Many of these work well with stuffed figures, bundles of hay, &c., in experiments, but fail in actual service, for while an inanimate object will always fall in a certain way when struck in a certain way, there is no knowing how a man may fall, according to his position when struck and his endeavours to avoid a fall. Owing to the oscillations of the car, fenders projecting beyond the ends must be placed so high that they may easily pass over a child or even a man lying on the track.

*Sea channel and breakwater.*—At Block Island, R.I., a channel is to be made to connect Great Salt Pond with the ocean, the channel being dredged through a sandy strip of land, and the ocean end protected by sand-tight breakwaters. The mean rise and fall of tide is $2\frac{1}{2}$ft. in the sea and 6in. in the pond. The channel will be 300ft. wide at the top, 250ft. wide on the bottom, with a depth of 15ft. of water at mean low tide. The breakwater jetties will consist of a row of piles 12ft. apart, driven 10ft. deep, connected by two stringers or waling pieces, and sheathed on one side with grooved oak planks 3in. by 10in., driven 3ft. deep, with the top 5ft. above low water and fastened by 6in. galvanised spikes, making a sand-tight barrier. These will be carried out to 11ft. of water. The piles will be of white or yellow oak with the bark left on, at least 12in. diameter at the butt and 7in. at the top, inside the bark. On each side of the barrier will be deposited a core of broken stone or "rip-rap," consisting of chip stones 3ft. wide placed 18in. on each side of the planks. The foundation of the breakwater will be a single layer of stones 2ft. thick, and not less than half a ton in weight, laid on the largest surface and placed as close together as possible, the spaces between them being filled by smaller stones. The stone used must be of angular shape—not boulders—weighing at least 140 lb. per cubic foot. Excavated material will be measured in the scows or barges, the capacity of each scow or barge being determined beforehand; and in making deductions for deficiencies in loading, or for dredging below the specified depth, four yards *in situ* will be taken as equivalent to five yards in the scow.

*Notes on permanent way.*—Some extracts from notes made during a recent professional trip may be of interest to railway readers of The Engineer. The Lehigh Valley Railroad is an important line with an enormous coal traffic. It is double line all the way from New York to Buffalo, 458 miles, this being its main line or "backbone," and the main tracks are laid with 80 lb. rails, spliced by heavy 30in. angle fish-plates of the Sayre pattern, with six bolts spaced 5in., 4in., 4in., 4in., and 5in. centre to centre. The bolts have button heads outside the rail and hexagon nuts and spring nutlocks inside. The rail ends are cut at an angle of 45 deg., this being about the only road which now follows this practice to any extent, and while the track rides easily and the rail ends show an even wear, these results are almost certainly due to the stiff and heavy joint fastenings rather than to the angle-cutting of the rail ends. The rails are laid with broken suspended joints, and there are 16 ties to a rail length of 30ft. The joint spacing of the rail ends is irregular, and during the hot weather of June, while many of the joints were quite closed, others had a space or $\frac{1}{2}$in. to $\frac{5}{8}$in. measured on the square. There are very heavy grades on the mountain division crossing the Alleghanies. The Western New York and Pennsylvania Railroad has a network of main and branch lines aggregating about 640 miles. The main line is laid with 67 lb. steel rails, and while English-made rails of this weight lasted well for twelve years' service without battering of the ends, the newer American rails have been much less satisfactory. This has been the experience of several railways, and while no doubt due in part to the increased wheel loads and increased traffic, it is certain that the average steel rails to-day are of decidedly inferior quality to those made more carefully at a time when higher prices prevailed and more care was taken in the manufacture. There is no trouble in making good rails in the United States now if only the railways will insist upon getting them, and will recognise the economy of a good price for a good article, as some railways have already done. The rails are $4\frac{1}{2}$in. high and $4\frac{1}{2}$in. width of base, with flaring sides to the head, $\frac{11}{32}$in. top corner radius, and 11in. top radius. They are laid with broken suspended joints, spliced by 26in. angle fish-plates with four $\frac{3}{4}$in. bolts spaced 6in., $6\frac{1}{4}$in., and 6in. centre to centre. The plates weigh $42\frac{1}{2}$ lb. per pair, the bolts and nuts $87\frac{1}{2}$ lb. per 100, and the Goldie sharp pointed spikes 60 lb. per 100. The bolts have square nuts $\frac{3}{4}$in. by $1\frac{1}{4}$in. The ties are mainly of white oak, costing about 60 cents each, and are spread only just far enough apart for shovel tamping, giving generally sixteen ties to a rail, with the joint ties spaced 10in. between the edges of the top faces. The ballast is of coarse and rather dirty gravel, with a considerable admixture of large rounded pebbles. Bridge sleepers are 6in. by 8in. section and 10ft. long, spaced 4in. apart, and the bridge floors have outside wooden guard rails and inside iron guard rails, the latter being brought to a point on the approaches. One large iron bridge has a solid floor of built-up rectangular troughs, with sleepers 8in. by 11in., and no ballast, as it is considered better to keep the ironwork free for inspection and painting. The Buffalo and Susquehanna Railroad is principally a lumber line, tapping the timber resources of the Alleghanies. There are five or six "switchbacks" or "reversing stations," and the maximum grades are $2\frac{1}{2}$ per cent. in getting through the mountains by a steep and winding location. The permanent way is of 60 lb. and 70 lb. steel rails, spliced generally with 24in. four-bolt angle fish-plates, but in some places larger six-bolt angle fish-plates are used. On the older rails the 24in. plates have bolts spaced 5in., 8in., and 5in. centre to centre, while the bolts of the heavier rails are spaced 6in. centre to centre. There are plenty of ties, and the ties are of ample width, but not stripped of bark as they should be. On heavy curves bridle rods are sometimes used, three rods being used to a rail length. This is on account of the great strain due to the heavy engines.

*Tramway track.*—A committee appointed to report upon the best type of rail for the street railways of Detroit recommended the use of either girder or grooved girder rails. The former should weigh at least 60 lb. to 70 lb. per yard, and be $5\frac{3}{4}$in. high, with the paving bricks or blocks—shaped to fit the web of the rail—level with the top of rail head on the outside and $\frac{1}{2}$in. below it at the inside of the track. The grooved rail should weigh not less than 70 lb. to 80 lb. per yard. The city of Port Huron uses ordinary flange rails of 45 lb., laid on pine stringers 5in. by 5in., which rest on cross sleepers 3ft. centre to centre. Oak or pine strips 2in. by 2in. fill the space under the rail head. The grooved girder rails used in Detroit weigh $77\frac{1}{2}$ lb. per yard, with the guard side of groove not more than $\frac{1}{4}$in. below the running side. The rail is $6\frac{1}{4}$in. high and 4in. wide, spiked to white oak ties, 3ft. centre to centre, the gauge being maintained by tie-bars 1in. by $1\frac{1}{2}$in. at intervals of 8ft. The paving—asphalte, granite, brick, and wood—is laid close against the rail head, and the space against the rail web filled with cement grouting. At Toledo the old flat side-bearing rail is used, with paving level with top of rail, so that there is a groove $1\frac{1}{2}$in. wide and 1in. deep, which is very objectionable. At Chicago the rail specified by the Public Works Department is a girder rail 5in. to 6in. high, with a running head 3in. wide, so as to carry wagon wheels and avoid rents alongside the rail head. At Columbus, flange rails, 62 lb. per yard, are used, and have electrically-welded joints.

*Mails and goods on electric railways.*—The advantages derived by country electric railways in carrying goods and parcels traffic has more than once been referred to, and the latest example is at Brooklyn, N.Y., where mail cars have been put on to run to Coney Island, a summer resort about ten miles distant from the post-office and situated on the Atlantic coast. The electric railway in connection with the post-office department has put on two mail cars, having the forward part fitted up with pouches and pigeon holes for letter sorting, while at the rear end is a passenger compartment for smokers only. The cars are 28ft. long, painted white with gilt lettering, like the standard U.S. railway mail cars, and cost 2000 dols. each. Several stops are made and pouches delivered and taken on along the route. The first stop is at Fifth-avenue and Twelfth-street, where a pouch is delivered to a collector for Station V and mail is received. At Fifth-avenue and Thirty-sixth-street the mail is transferred to another car, which runs over the Brooklyn, Bath, and West End route to Coney Island. Mail is delivered and received at West Brooklyn, Blythebourne, Bath Beach, Van Pelt Manor, Unionville, and Coney Island, and sorted on the way. The trip from the post-office to the West End station in Coney Island is made in sixty-six minutes, and the return trip in sixty-two minutes, the same stops being made. When the system is in complete operation four daily trips will be made. Considerable saving, both in time and money, is effected by the new system. The electric railway is proving a great factor in opening up suburban districts—as people do not have to live up to a time table as they do if they take the steam railway—and in connecting country towns; but in some states the charters only give the right to carry passengers. If this is changed to allow baggage, parcels, and freight to be carried, such electric railways will become even more valuable properties, as proved by experience on roads where such traffic is carried. Suburban roads generally follow the roads—but not always, especially on long lines—but country lines are very generally located and built on their own land like ordinary railways. The cost of construction and equipment is, of course, very much less than where steam locomotives have to be carried.

*Irrigation.*—A proposition has been made by a California irrigation company for irrigating the Pecan Valley, Texas. It is proposed to construct a system of ditches, for the sum of 3·30 dols. per acre for ten years, if the people will take up 50,000 acres of irrigated land. The Mitchell Canal in Nebraska is to be extended about fifteen miles, crossing the "bad lands," and will be enlarged to greater capacity. The canal will then be nearly fifty miles long. The Saticoy Irrigation Company, in California, is having surveys made for a pipe line thirty miles long, to bring water from the Santa Clara River. Perkins County, Nebraska, has voted to issue bonds for 90,000 dols., to assist in the construction of a canal sixty-five miles long, which will cross that country.

*Railways.*—No large projects are under way, but there is some activity in small line, particularly in lumber districts. In Maine the Wiscasset and Quebec, 24in. gauge, has twenty miles of grading completed, forty miles under way, and fifteen miles not yet cleared. The reason for adopting this gauge is not clear, as the road bed is of standard width, and the line crosses two standard gauge roads, with which connection will sooner or later be required. When completed there will be about 150 miles of 24in. gauge road in this state. In Canada the Canada Atlantic Railway is pushing work vigorously on its line west from Ottawa to Parry Sound, a port on Georgian Bay, and this line is all the way through a timbered country. A large number of subsidies has been granted by the Dominion Government. The Coast Railway of Nova Scotia has let contracts for a line ninety miles long, extending from Yarmouth to Lockport. The Port Arthur, Duluth, and Western Railway will extend its line in Canada to the recently-discovered gold mines of the Rainy Lake region. A new and important route between Buffalo and Pittsburg will be effected by the construction of seventy-five to one hundred miles of connecting links between the lines of three companies, and a double-track line into the city.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

Business in the manufactured iron and steel trades maintains the improvement recently noticeable, and prices of sheet and bar iron are kept fully up to the quotations given last week. The general attention which is being paid just now to the subject of Belgian competition has led to the disclosure of some remarkable instances. Certain classes of steel hoops are being landed in London from Antwerp at £1 per ton less than Staffordshire makers are quoting; and in some sorts of girders for contractors' purposes, both steel and iron, the difference is even greater than this.

Gasholder engineers are among the latest sections of the community in this district to benefit by Belgian cheap labour and long hours. For in addition to rolling, as they have long done, iron and steel girders and joists for building, the Belgian ironmasters have now begun the manufacture of sectional steel for gasholder engineers. Midland buyers who have given Belgium a trial state that the particular sections of steel they have ordered successfully bear all tests, and that the material is far cheaper than that of British make. By laying down special rolls the Belgians are indeed beginning to cultivate a trade in this and somewhat similar classes of steel which they are likely to find decidedly lucrative. This further information as to Belgian competition enforces the lessons which iron and steel masters, returned from the meeting of the Iron and Steel Institute at Brussels, bring, of the necessity for increased vigilance by our own manufacturers, if we are to keep pace with Belgium. The opinions of these authorities, which have been expressed this week and last, have occasioned great interest among iron and steel masters in this district.

It is matter for satisfaction that though the total exports of galvanised sheet iron from this district to foreign markets are not just now much increasing, yet as regards Australia and the Cape, the purchases of both these colonies are steadily going up. In the past month the buying by Australia was of the value of £46,612, against £41,455 this time last year; and the purchases of the Cape were worth £24,445, against £18,174 a year ago. The other chief customers of this district were India, the Argentine, and miscellaneous markets. The total exports to all markets for this year, so far as it has run, are of the value of £1,293,223, against £1,356,847 in the first eight months of 1893.

American orders have been received in this district since the passing of the tariff for special qualities of tinned sheets worth £24 10s. per ton. Midland makers doubtless contributed to some extent to produce the improvement of 3341 tons of tin-plates which went to the States last month in excess of the same month a year ago; the newest total being 19,123 tons. Most of the Midland manufacture lies, however, in best sheets for deep stamping purposes rather than the ordinary run of tin-plates for transatlantic canning services.

The steelmasters are better employed than for a long time past. Orders are arriving from both British and foreign customers, and the converters and cogging and rolling mills are decidedly busy. Prices are strengthening. Bessemer tin-plate bars are quoted £4 2s. 6d.; boiler tube strip, £6 10s. to £6 15s.; bridge plates, £6 15s.; boiler plates, £6 5s.; and plating bars, £5 2s. 6d.

Pig iron rules firm at 38s. 6d. for Staffordshire cinder sorts; 41s. 6d. to 42s. for Northamptons; 42s. to 43s. Leicestershire and Wiltshire; and 51s. to 52s. 6d. for Welsh hematites.

The bridge and roofing makers have a good deal of home railway work in hand just now; one of the most recent contracts received being for as much as 16,000 tons of ironwork. Steel bridge work is also under execution for Japan, India, and other Eastern markets. Hot water engineers are busier than recently upon the manufacture of heating apparatus for public institutions.

The mechanical engineers and locomotive builders of the Midlands are gratified to find that the British export trade, though apparently on a retrograde plane as regards most of the industries of the country, is yet still progressing in the great departments in which they are chiefly interested. They are glad to see an advance in the value of steam engines of 14 per cent. for the month, and 2 per cent. for the eight months; and in machinery of 10 per cent. and 5 per cent. respectively. Our August exports of steam engines were of the value of £316,729, as against £275,525; and those for the eight months were worth £2,090,807, compared with £2,048,120. Machinery for August rose from £875,620 to £971,347, and for the longer period from £6,931,174 to £7,344,756.

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester.*—Although a quieter tone has come over the iron trade so far as further buying of any weight is concerned, the recent spurt of business has left behind it a better feeling in the market, and the advance in prices has been maintained. The position, however, as regards the large iron-using industries, still shows no really appreciable improvement. In this direction no materially increased activity is reported, nor does the present outlook indicate any large volume of trade coming forward in the immediate future.

Only a moderate business was being put through on Tuesday's Manchester Iron Exchange, but prices were firm at the full rates quoted last week. Lancashire makers, who have not moved at all in the way of advancing their list rates, still report a moderate business doing at about 40s. for forge, to 42s. for foundry, less $2\frac{1}{2}$ at the works, representing about 42s. 6d. for forge, to 44s. 6d. and 45s. for foundry, delivered Manchester or district. In some of the district brands where makers have not put up their prices to quite the same extent as those who are so fully sold that they are indifferent about booking further orders, some fair transactions are being put through at about 39s. 6d. for forge, to 40s. 6d. for foundry, net cash delivered Manchester; in other cases, however, 40s. for forge to 41s. for foundry, net cash, is being held for, but these prices check further buying, consumers, who have satisfied present requirements, preferring to wait. For Derbyshire foundry iron quotations remain at about 45s. to 46s. net cash, delivered Manchester, but no business of any moment is reported. For outside brands offering here prices continue exceedingly firm at, if anything, slightly above last week's quotations. Good-named foundry brands of Middlesbrough are scarcely obtainable under 45s. 4d. net cash, delivered Manchester, whilst for the very small quantities of Scotch iron now in the market prices continue to harden, and it would be difficult to buy Eglinton under 49s., whilst 51s. has been paid for Glengarnock, net prompt cash, delivered at the Lancashire ports.

Finished ironmakers still report no appreciable improvement in this branch of trade. Some of them are perhaps rather better off for orders than they have been recently, but they are still short of work to keep forges anything like fully going, and the only extent to which they are in any really better position is that buyers are not pressing for such excessively low prices, and makers are able to maintain something like their quoted rates. Lancashire and North Staffordshire bars are firm at £5 7s. 6d. to £5 10s.; Lancashire and Staffordshire sheets, £7 to £7 5s.; and Lancashire hoops, £5 17s. 6d. for random, and £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

Nut and bolt makers report business coming forward rather more freely, but no better prices ruling.

A considerably increased weight of business is reported in some quarters as being put through in the steel trade during the past week or so, and for hematites better prices have been obtainable, ranging from 53s. to 53s. 6d., less $2\frac{1}{2}$, for good foundry qualities, delivered Manchester. Ordinary basic billets are still obtainable about £4 net cash delivered here. With regard to manufactured material, bars are quoted at £6 and steel boiler plates at £6 7s. 6d. to £6 10s. delivered in the Manchester district, but these figures are not at all readily obtainable.

In the metal market the downward tendency in raw material has quite put a check on further buying in manufactured goods at the recent advance on list rates, but these remain without change.

Here and there rather more work is reported to be stirring amongst engineers, but the position generally does not show any real improvement, and for the most part establishments continue but moderately supplied with orders with low cutting in prices to secure any business coming forward. The reports issued by the engineering trades union organisations also show no material change in the position. The Amalgamated Society of Engineers return a slightly lessened number of out-of-work members on the books, but this still remains at nearly 10 per cent. of the total membership. In the Manchester district, owing chiefly to suspensions at one of the large engineering establishments, there has been a further increase of unemployed members during the month, and there are now about 9½ per cent. of the local membership in receipt of donation benefit. The reports from the various districts connected with the Association show no improvement in the outlook as regards industrial prospects, but it is hoped that the settlement of the strike of moulders on the north-east coast, which has not yet made itself felt as regards the present returns, will tend to improve the position of the society, and that the report for the next month may show a considerable decrease in the number of out-of-work members. The returns issued by the Steam Engine Makers' Society show no appreciable change as regards the number of out-of-work members, which still represents more than 5 per cent. of the total membership on donation benefit, whilst the reports as to the condition of trade show no improvement.

The quarterly meeting of the Manchester Association of Engineers was held on Saturday, Mr. T. Daniels, the President, in the chair. The business was entirely of a formal character, relating chiefly to financial matters, and the nomination and election of members. Messrs. A. J. Bailey, of Sir Wm. H. Bailey and Co., Salford; J. E. Hobson, of the Engine, Boiler, and Employers Liability Insurance Company, Manchester, were elected honorary members; and Mr. J. R. Ingham, of Kendall and Gent, Salford, an ordinary member of the Association. Arrangements have been made for opening the ensuing session on Saturday, October 13th, on the afternoon of which day there is to be an inspection of the Manchester hydraulic and electric installations.

The considerably increased pressure at which boilers have now to be worked, as compared with what was considered requisite or possible a few years back, has of necessity compelled special attention to improvements in steam fittings, and it will be interesting to notice several new designs in this direction recently introduced by Messrs. Fletcher Bros., of Ashton-under-Lyne. One of these is a patent blow-off cock, specially designed for high-pressure. Hitherto the method of compressing the plugs and packing has been to first compress the packing, which in turn compresses the plug. As the compression of a mass of packing is objectionable in large cocks, Messrs. Fletcher have introduced a new arrangement with a patent cover gland, which, upon compression, acts directly upon the plug, metal to metal, and also compresses a loose ring, which acts upon the vertical and horizontal slots of asbestos, so that by screwing the bolts the four slots and the top and bottom packing, along with the plug, all become compressed. A patent triple safety valve is another improved fitting specially adapted for Lancashire boilers working at 200 lb. pressure. In this valve, instead of having one hanger, as usual, for the low-water arrangement, the boiler-plate is cut to a special plan, and two bolts are hung from the boiler shell. This arrangement brings the action of the valve much closer to the fulcrum, so that a dead load of 7 cwt. can be raised. Another important feature is that all the valves are mounted on one riveting base, thus saving extra holes in the boiler. In the old easing gear, when loaded up for 200 lb., the difficulty has been that with the boiler pressure low it has been found almost impossible to move the easing lever, but in Messrs. Fletcher's design this difficulty is avoided by mounting the valves with loops or stirrups and the easing valve with excentrics, so that the easing can now be done with two fingers of the hand, although there may be no assisting pressure in the boiler. The two high steam valves and the low-water valve are all mounted on the one casing, and the steam issuing from the low-water valve is conducted away by a separate branch. Amongst other new designs which the firm are introducing is a patent steam-reducing valve. In the old system of lever and weight good results could not possibly be obtained when reducing from 200 lb. to 17 lb. with one valve. The cut-off ports in the old valves were always placed closed to the corresponding ports for receiving the pressures, so that at the slightest motion the valve was open and passing steam, but in the new deadweight system designed by the firm the inner ports are carried a considerable height up the casing away from the ports taking in the pressure, so that plenty of lap or bearing is obtained when the reducing valve is required to cut off steam. This valve, which is very simple in construction, having no levers, links, or pins, has a piston packed with asbestos, and waste condensation water is entirely dispensed with. For marine purposes a spring takes the place of the deadweight.

The coal trade still shows no appreciable improvement, except, perhaps, some increasing inquiry for the better qualities, which of course is looked forward to at this season of the year. Common round coals, however, continue in very limited local request for iron-making, steam, and general manufacturing purposes, and engine classes of fuel remain quite a drug in the market, with prices, if anything, a trifle easier since the break-up of the Coal Sales Association, and excessively cheap supplies still come in from other districts. Pits for the most part are not working more than four days per week, and supplies of all descriptions of fuel are in excess of requirements. The average market rates remain at about 11s. for best Wigan Arley, 10s. for Pemberton four-foot and seconds Arley, 8s. for common house coal, 7s. to 7s. 6d. for steam and forge coal, and from 3s. 6d. to 4s. for common slack to 4s. 6d. and 5s. for medium up to 5s. 6d. and 5s. for the best qualities.

There is still a fair amount of activity in the shipping trade, but with the prospects of an early settlement of the Scotch strike buyers are more cautious about placing orders, and there is some pressure for lower prices than have been ruling. There is, however, no quotable change, and delivered at the Garston Docks, or the High Level, Liverpool, ordinary Lancashire steam coal remains at about 8s. 9d. to 9s., and engine fuel at about 5s. 6d. to 5s. 9d. per ton.

*Barrow.*—There is a very quiet trade doing in hematite qualities of pig iron, and the week's business has not been an improvement in any sense on recent experiences. Makers are booking but few new orders either for Bessemer or ordinary hematite, and the foreign and continental demand is exceptionally quiet. On home account very little is being done, and were it not for the pig iron which is used in the district for steel-making purposes, very little business would be done. Prices are rather higher at 44s. 11d. buyers of warrant iron net cash, and makers are asking 45s. to 46s. for parcels of mixed Bessemer numbers net f.o.b. There are only thirty-three furnaces in blast, compared with thirty-four in the corresponding week of last year. Stocks of pig iron have been reduced during the week 257 tons, and now stand at 158,066 tons, being an increase since the beginning of the year of 63,443 tons.

Iron ore is selling very badly. The Scotch trade, owing to the strike, has been reduced to a minimum, and very little ore is at present being shipped out of the district. Local smelters are not using much. Prices are steady at 8s. 6d. for ordinary, and 12s. to 14s. for best sorts, net at mines.

Steel makers report a slight improvement in tin-plate bars, but a quiet tone in all other branches of trade except that of steel plates for shipbuilding purposes. Makers are fairly off for orders in this department. Steel rails are especially quiet, and very small parcels only are inquired for. The winter's outlook in nearly every department of the steel trade is cheerless. Prospects do not improve as the season proceeds.

Shipbuilders and engineers do not report any new orders, but several good inquiries have recently come to hand which it is hoped will lead to business. Some preliminary trials have been made this week with H.M. ship Sturgeon, one of the three torpedo boat destroyers building here for the Admiralty, and very satisfactory results are reported. The new sand dredger built at Barrow for Kingstown Harbour has been completed and delivered to her owners at Dublin. Satisfactory trials of her working capacity have been made.

The coal and coke trades are very quiet, and deliveries are necessarily small. Prices are steady at 17s. for East Coast coke delivered at West Coast furnaces.

Shipping is still indifferently employed. During last week the exports of pig iron from West Coast ports represented 3513 tons, and of steel 6605 tons, compared with 2110 tons of pig iron and 8636 tons of steel in the corresponding week of last year, an increase of 1403 tons of pig iron and a decrease of 2031 tons of steel. The aggregate shipments for the year so far have been 254,061 tons of pig iron and 283,343 tons of steel, compared with 190,111 tons of pig iron and 355,846 tons of steel in the corresponding period of last year, being an increase of 63,950 tons of pig iron and a decrease of 72,521 tons of steel.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

House coal continues to be in fair demand, and the tonnage forwarded to London is about an average. Although the season is advancing there is no forward buying, merchants apparently still clinging to the belief that there will be a fall in prices. Silkstones at present make from 9s. 9d. to 11s.; Barnsley house coal, 8s. 6d. to 10s. 3d.; lower grades about 1s. to 1s. 6d. cheaper. In steam coal the Humber ports are still taking a good weight, business being up to the average. Barnsley hards are from 7s. 9d. to 8s. 9d. per ton. Secondary qualities from 7s. per ton. Gas coal is in better request at from 7s. to 8s. per ton. The depressed business in wool and cotton manufacturing districts prejudicially affects the demand for slacks, which are easily obtainable at 4s. to 5s. per ton, smaller coal being as low as from 2s. The owners of house coal pits complain of the cost of the carriage of coal to London, the reduction of the railway ton of 21 cwt. to 20 cwt. making an additional cost of fourpence a ton in carriage. The owners say that the consumer is not paying it, and that it was unwarranted at the first; they therefore are agitating to have it removed. It is said that the Coal Trade Association is about to test the right of the railway companies to make this alteration in the rates of carriage for coal, which practically means an advance of 5 per cent. Coke is now making from 8s. 6d. to 10s., which represents an advance of fully threepence per ton on the fortnight. The tone of business is more hopeful.

Messrs. Newton, Chambers, and Co., Thorncliffe collieries, who send an enormous tonnage by rail to London—probably the heaviest weight sent by any English colliery company—are now quoting house coals as follows:—Best Mortomley, 16s. 6d.; Mortomley brights, 13s. 9d.; best Mortomley nuts, 14s. 6d.; seconds do., 11s. 6d.; thin seam, 15s.; brazils, 13s. 6d.; Tankersley house, 12s.; Parkgate softs, 10s. These are the prices at Sheffield per 20 cwt. They are the lowest summer rates, which will be raised, it is expected, 1s. a ton in October, when there is generally an advance made in values. In the iron trade a general improvement is reported. An advance of 2s. per ton in pig iron is encouraging the blowing-in of other furnaces. These, by increasing the output, will probably check an advance in values. Hematite pig iron is now making from 51s. 6d. to 54s. per ton, according to the brand; forge iron from 39s. to 40s., delivered at Sheffield. Iron is being generally stocked in expectation of better business. Bessemer billets are about £5 10s. per ton; bar iron £5 10s. to £5 15s. at makers' works; common wire rods £5 5s.; rope rods and high carbon rods, £8 8s. At present there is no improvement reported in the shipbuilding trade, the moulders' strike in the North interfering very considerably with that important industry. All round, however, there is a more cheerful tone and very considerable accessions to business may shortly be expected.

The official returns of the Hull Chamber of Commerce and Shipping for the month of August exhibits the tonnage of coal imported and exported at the chief Yorkshire port, and is particularly interesting on account of its being the first month in which the coalowners have realised the benefit of the 10 per cent. reduction in wages. August is also the anniversary of the first month of the great struggle of last year. The figures, of course, show a great advance over the trade done twelve months ago, but they still justify the fact that business once lost is difficult to win back. The whole of the Yorkshire collieries sent to Hull last month 181,896 tons of coal, as compared with 83,248 tons in August of 1893. This weight, it will be seen, is more than double the business done twelve months ago, but it is still considerably less than the tonnage of August, 1892, when the weight amounted to 213,672 tons. For the completed period of eight months the weight was 1,328,200 tons, as compared with 1,006,485 tons in the corresponding period of 1893, and 1,520,592 tons for the eight months of 1892. South Yorkshire still holds the first position. Denaby Main continues to head the list with 21,696 tons sent during the month, and 156.664 tons during the eight months. New Sharlston, a West Yorkshire colliery, takes second place for the first time with a weight of 10,560 tons for the past month; Monk Bretton is third with 10,192, and Aldwarke Main fourth with 8744. Five South Yorkshire collieries sent 56,144 tons, or 30 per cent. of the whole. In West, as in South Yorkshire, large collieries also took the trade. Thirteen South Yorkshire collieries sent half of the whole amount, and after them seven collieries in the West accounted for a third of the balance. The exports to foreign countries reached 113,060 tons, against 37,849 tons in the same month of last year, and 99,374 tons in August of 1892.

The manufacture of cotton ties for the United States was for years an important Sheffield industry, from twenty to twenty-two thousand tons being sent annually to that market. The McKinley Act completely killed business, not a single tie having been sent into the States since 1890. Although the duty has been largely reduced by the new tariff, from 100 per cent. to 30 per cent., it is not expected that the relief will be sufficient to revive the trade, the value of the ties having gone down largely of late years. They are now supplied at £6 7s. 6d. free on board at Liverpool, and the duty on that price still remaining at £2, is simply prohibitory. The Americans are making ties of basic steel cheaper than of iron, the cost for puddling iron in America being 16s. 6d. per ton against 7s. 6d. per ton in this country. The American steel ties are now almost universally used by the cotton growers to bind their bales. Petroleum hoops are also affected, but this has been a diminishing business for some time, owing to the freer use of pipes for the conveyance of the oil from the wells to the tank steamers, in which the petroleum is now largely conveyed abroad. Our tie manufacturers are finding the Australian trade considerably better. There the ties are used for binding the bales of wool sent to this and other countries.

The exports of hardware and cutlery for the month of August are somewhat discouraging, there having been a continuous decline during the three years. The value sent last month was £151,178 against £166,983, and £185,326 for the corresponding months of 1893 and 1892. The principal decreasing market has been the United States; but as the settlement of the tariff question has again resulted in the re-opening of business, the exports to the United States from Sheffield having doubled, a marked improvement will be looked for in the official return for September. For the eight months of the year the value of hardware and cutlery exports was £1,197,494, against £1,385,878 and £1,450,641 for the similar period of 1893 and 1892. In steel unwrought there is a gratifying advance to be reported, the value of exports last month having been £183,717, against £157,757 and £149.280 for August of 1893 and 1892. Russia, Germany, and the United States have all taken largely increased values. Russia has risen from £13,934 to £38,219, Germany from £22,776 to £39,548, and the United States from £24,986 to £38,240. Decreases, on the other hand, are reported from Sweden and Norway, Denmark, Holland, British East Indies, and British North America. For the eight months the value is £1,247,403, as compared with £1,158,412 and £1,140,987 for the similar completed periods of the two previous years.

Proof still continues to be afforded of the disastrous effects of the seventeen weeks' stoppage in the coalfield. The Staveley Coal and Iron Co., one of the largest concerns in this district, points to its balance sheet as showing the effect of that calamity on its operations, which reduced the dividend for the year. The Sheepbridge Coal and Iron Company report that its works were suspended for a considerable period during the strike, "which caused a heavy loss to all concerned." The directors report that they have brought into the current account the sum of £11,448, carried last year to the strike reserve fund, and have debited the loss caused by the strike to the profit and loss account of the financial year just closed. The hope is expressed that the newly-formed Conciliation Board will do much to make such trade conflicts impossible in the future.

One of the best of our distant markets at present for Sheffield productions is South Africa, which is taking tools, files, and cutlery in quantities which are continually augmenting every week. There is rather more doing also with the Argentine Republic, while the Australian markets are reported to be recovering so very slowly.

The South Yorkshire Colliery Enginemen's Association, which comprises five branches—Sheffield, Hoyland Common, Swinton, Wombwell, and Barnsley—are resisting the reduction of 10 per cent. decreed by the Conciliation Board. They state that as they were not represented on that Board they decline to be bound by its decisions, and demand that no reduction should be made in their wages. The secretary of the South Yorkshire Colliery Owners' Association has acknowledged receipt of the letter, and the Council of the South Yorkshire Colliery Enginemen have given it to be understood that, unless their demand is complied with, complications and unpleasantness will result.

Mr. Charles Henry Bingham, of the well-known silver-plating and cutlery establishment of Messrs. Walker and Hall, electro works, Howard-street, Sheffield, was duly installed on the 6th inst. as Master Cutler of Sheffield. Mr. Bingham is in partnership with his brother, Lieut.-Colonel J. E. Bingham, J.P., who has twice held that office with equal ability and acceptance. It was during his second tenure of the post that a most successful Handicrafts Exhibition was opened at the Cutlers' Hall by H.R.H. the late Prince Albert Victor, who was the colonel's guest. The other partner in the firm is Captain A. E. Bingham, son of the Master Cutler's brother. The new Master is a gentleman who has taken an active interest in questions affecting the social and material welfare of his native city, and has been a leading member of the Sheffield Smoke Abatement Association, which has already done substantial service in brightening the conditions by cleansing the atmosphere in which some 340,000 people pursue their daily avocations.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

A general improvement in the iron and allied industries can fairly be reported, and the tone of manufacturers' forecasts has quite changed from what it was a few weeks ago. They are no longer "down in the dumps," but all speak hopefully of the future, and express belief that the revival of trade, so long looked for, has set in. Consumers are evidently of the same opinion, as they are prepared to buy for delivery over a considerable period at the present prices, which would hardly be the case if they had reason to believe that the current improvement was nothing more than a spurt. Speculators are also taking hold more of pig iron, and have no hesitation in operating, especially in pig iron, as they think that they will be able to speculate profitably, for prices are more likely to advance than to fall back. For some years they have not touched iron, as they could employ their money to better advantage by operating in other metals. People also are inclined to put more faith in an improvement which sets in during the autumn months, for an autumn start has usually meant a revival which has lasted for a considerable period. It is, however, probable that business may not be very lively this year, but still there is much more doing than there has been at any time this year, and better prices are generally being realised, not only in the pig iron but also in the finished iron and steel trades.

As yet the ironfounding and engineering industries have not experienced any of the revival, but both these still feel acutely the effects of the long strike of moulders, and the dulness that continues in the shipbuilding industry. The strike is over, it is true, but comparatively few of the workmen have been able to resume their employment, because the work is not there for them, and it may be weeks before the masters will be in a position to give them work. The cessation of the strike has not meant the simultaneous resumption of employment, except for a very small proportion of the men who were on strike, because their action has driven away to other districts, and even to the Continent, a large proportion of work which would have in all probability been executed in this district if there had not been any strike; and the outlook for the winter for them is not encouraging, because the shipbuilding industry is so depressed, and it is hardly likely that many new orders will be given out, because profitable employment cannot be found for a large number of the steamers that are now running, freights being so low—in fact they are to many ports lower than were ever before known; and many vessels are laid up on our rivers. Thus ordinary shipowners find they have enough to do to manage steamers already running, without ordering more steamers, and thus increase the glut, and the difficulty of making the property pay. Probably never was the difficulty greater of making ends meet in the shipping trade, and it would be better for the owners if more steamers were laid up. Many builders have idle berths, indeed on the Tyne more than half the berths are unoccupied. In face of this it is hardly likely that the moulders can succeed before the Conciliation Board in obtaining any advance of wages such as they have been obtaining during the last six months, and it seems more probable that wages will be reduced. Probably if they had not struck they might have been able by this to secure even more than they asked in March. But their action did much to paralyse business, and it may be some time before a recovery of their trade is experienced. The pattern-makers have not seen their way to follow the example of the moulders, but still remain on strike, and for the original amount, viz., 10 per cent. on piece prices, and 3s. 6d. per week on time wages. Efforts have been made this week to induce them to have the dispute settled, like that of the moulders, by arbitration or conciliation, but the men reject the offer.

The demand for Cleveland pig iron increases, and prices now are better than they were last week. In No. 3 Cleveland G.M.B. a little business was done early in the week at 36s. 3d. per ton for prompt f.o.b. delivery, but the sales were made by second hands, and were practically of odd lots. The producers have generally held out for 36s. 6d., which they have been able to realise; indeed, some firms have obtained 37s. where their brand was particularly needed, and where it could not be bought from merchants or the public warrant stores. As a matter of fact there are several brands of pig iron that never find their way into the public stores, the makers stipulating when they sell the iron that it must not go into the stores, and it is bought on that understanding. Several makers are badly off for No. 3, because their furnaces have not worked well since August 11th, and the roportion of No. 3 made has fallen below the average, so that producers have not in all cases been able to fulfil their orders as promptly as required. Cleveland warrants have been moving upwards this week, and have reached the best price that has been quoted since the improvement commenced. This rise has brought in more speculators, and there is a likelihood of a lively time in the warrant market. On Wednesday the closing price was 36s. 8d., cash. The stock of Cleveland pig held by Messrs. Connal and Co. on Wednesday night was 91,061 tons, or 672 tons increase this month. It might have been expected that as No. 3 is so scarce, the stock in the public stores would be more largely drawn upon. But deliveries are quiet on export account, and the shipments of pig iron from Middlesbrough this month have reached only 25,370 tons, against 27,413 tons last month, 42,965 tons in July, and 34,045 tons in September, 1893, all to 12th.

The lower qualities of Cleveland pig iron are in improving request, and makers look for a large demand when the Scotch miners' strike collapses, as it is expected to do shortly, because the Scotch mills, forges, and foundries will recommence operations directly the strike is over, but will not be able to get supplies of the necessary pig iron from the local works, and will have to procure it from Cleveland. The stoppage of the Scotch furnaces has been very complete, only two remaining in operation. For Cleveland No. 4 foundry pig 35s. 3d. is quoted, and for grey forge 34s. 6d., and there is not much to be had under these figures. East Coast hematite pig has this week at last shown some improvement, and M. Nos. have been put up to 43s. 6d., though in some cases business has been done at 43s. 3d. Foreign ore is somewhat dearer, and as consumers are willing to buy for delivery over the next six months at the present price, it may be inferred that lower rates are not expected.

Business is more active in nearly all branches of the finished iron and steel trades, and the advanced prices are maintained. The steel rail makers have raised their quotation for heavy rails to £3 12s. 6d. net at works, not so much because of a better inquiry as because the cost of production has increased. Still there is more doing, and orders are expected to be more freely distributed this autumn than in any period of this year. The steel plate and angle manufacturers are maintaining their advanced rates, but buyers are chary about paying them, as they can hardly secure a corresponding advance from their customers. Steel ship-plates are at £5 2s. 6d. and angles at £4 17s. 6d., both less 2½ per cent. and f.o.t., but there are sellers at less. Palmer's Shipbuilding and Iron Co., Jarrow-on-Tyne, have secured an order for a 6000-ton steamer for the Peninsular and Oriental Steamship Company. It is only great companies like these that can afford to order new vessels at the present time. Common iron bars are sold at £4 17s. 6d. less 2½ per cent.; they have not moved for months, but there is now some improvement appearing. Bridge builders are somewhat better off, and have more encouraging prospects.

The directors of Bolckow, Vaughan and Co. state that the results of their operations during the first half of the year were fairly satisfactory, but they do not recommend the payment of an interim dividend, preferring to wait until the end of the year, when the results of the full year's working will be known. This was the course they pursued last year.

A committee of the Middlesbrough Town Council have visited the electric lighting works at Newcastle, Leeds, Bradford, Halifax, Huddersfield, and Blackpool, and make a very appreciative report on the subject. They affirmed that the electric light is a paying business, and a profit can be made by its adoption. It is superior to gas and its sanitary effects are in the right direction, and tradesmen's goods are not injured as they are with gas. The committee are of opinion that it would be in the true interests of the borough to proceed forthwith with the laying down of an electric light installation at a cost not exceeding £25,000. They deprecate the proposed spending of a large sum of money on the extension of gas plant. They think it is not desirable that a private company should obtain powers for Middlesbrough to be approached hereafter for purchase—as in the case of Newcastle—but recommend that the Corporation itself should obtain the necessary powers.

The coal trade is very brisk, and deliveries are good both by rail and sea. A large amount of business is coming into the district by reason of the Scotch strike, and prices all round are well maintained. The Elswick Coal Company has applied to the Collieries Committee of the Newcastle Corporation to be allowed to work the coalfield, extending to 350 acres, under the Town Moor. The present workings of the company afford a rent of £200 and 3d. per ton royalty to the Corporation, yielding an average of over £1000 a year. It was agreed to lease the new coalfield on similar terms, the rent being doubled, and the royalty at 3d. a ton increasing in the event of the seams of coal turning out exceptionally good.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

A MODERATE business has been done in the pig iron market in Scotch warrants, which have been firmer in price, selling from 43s. 7½d. to 43s. 9½d. cash. Cleveland iron is in poor request. There has been slightly more inquiry for hematite, Cumberland warrants selling at 44s. 10d. and 44s. 11½d. cash. Scarcely any interest is taken in warrants by the outside public.

The special brands of makers' iron are difficult to obtain, a number of them having indeed temporarily disappeared from the open market. G.M.B. f.o.b. at Glasgow, No. 1, is quoted 45s. 6d. per ton; No. 3, 43s. 6d.; Monkland, No. 1, 48s.; No. 3, 43s. 6d.; Carnbroe, No. 1, 49s.; No. 3, 46s. 6d.; Calder, No. 1, 58s; No. 3, 51s.; Summerlee, No. 1, 59s.; No. 3, 51s. 6d.; Coltness, No. 1, 59s.; No. 3, 52s.; Glengarnock at Ardrossan, No. 1, 54s.; No. 3, 49s. 6d.; Eglinton, No. 1, 54s. 6d.; No. 3, 48s; Dalmellington at Ayr, No. 1, 51s. 6d.; No. 3, 49s.; Shotts at Leith, No. 1, 56s.; No. 3, 51s. 6d.

There are now only two furnaces in blast in Scotland, and these are both at Coltness, producing ordinary iron. Since last week two were put out at Shotts, and the whole of the Scotch blast furnaces with the above exception now stand idle.

The shipments of pig iron from Scottish ports in the past week have been 1623, against 6641 in the corresponding week last year. There was sent to Australia 390 tons; Canada, 16; India, 75; France, 45; Germany, 171; Holland, 60; Belgium, 40; other countries, 10; the coastwise shipments, 818, compared with 3040 in the same week of 1893.

There is as yet no business of any importance in manufactured iron and steel. The annual report of the Steel Company of Scotland is an indication of the unprofitable state of business and of the evil consequences of the miners' strike, and it will be a considerable time before work can be anything like fully resumed. The high cost of fuel makes it impossible to keep the works going at present. One or two firms have made a start, but there is no chance of a general resumption of work until the colliers' strike is at an end.

It need scarcely be said that we are nearer the termination of the strike. The colliers are showing unmistakeable signs of their conviction that they are beaten. In consequence of the unsatisfactory state of trade and the gradual decline in prices, it was and is impossible to give the colliers any permanent advance of wages. At a number of collieries small bodies of men are working, and there are appearances of an early collapse of the strike.

The coal trade is quite disorganised. This week prices have been higher to the household consumer, and the demand for manufacturing purposes is also increasing, although there is still much room for improvement. The past week's coal shipments from all the Scotch ports amounted to only 9963 tons, against 180,467 in the same week of 1893. It will also be of interest to note that the total coal shipments for the current year to date show a decrease of fully 1,000,000 tons, compared with those for the corresponding period of last year.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THERE is certainly more animation in the iron and steel trades of late. In visiting the other day the admirably managed Alexandra dock, Newport, I was impressed with a picture, not seen at any other docks in Wales, of great quantities of rails and sleepers waiting their time for Delagoa Bay. These were principally from the Ebbw Vale Works, though Dowlais-Cardiff does considerably in steel sleepers for foreign destinations. On Tuesday a cargo of rails and sleepers amounting to 3500 tons was despatched. On the same day from Cardiff 600 tons iron went to Bilbao. In Bessemer and Siemens bars the leading works are more busily occupied of late. This week a very large despatch of bars took place from Cyfarthfa, and a good average from Dowlais. Prices are showing a hardening tendency, but in other respects quotations remain unchanged. In iron ore a good deal more business has been done, and numerous consignments have been received. Latest prices show an improvement. Rubio is selling at 11s. to 11s. 3d.; Tafna, 10s. 6d. to 10s. 9d.; Garucha, 10s. 6d.; Porman, 9s. 9d. to 10s.

There has been an increased make and export of tin-plate, and the tone of trade is manifestly improving. Last week the make in the Swansea district totalled 72,328 boxes, and the shipment 72,453 boxes. Stocks are now down to 311,453 boxes. Swansea imported 805 tons of pig iron last week and 490 tons tin bars. The Harbour trade generally was good, and the import and export very satisfactory. The total trade of the last week was 10,000 tons above that of the previous week, and 20,000 tons above that of the corresponding week last year. The prospects of an increased coal trade, by the Great Western Railway reductions from the Aberdare and Ogmore districts, are assured.

The patent fuel trade is fairly active, both at Cardiff and Swansea. From the latter port last week 2260 tons were despatched to France, 680 tons to Spain, 2150 tons to Italy, 1900 tons to Austria, 2840 tons to Algeria. A buoyant tone prevails throughout in connection with the coal trade, and each port records the dispatch of large tonnage. At Cardiff, mid-week, a full attendance again took place on 'Change, and a hopeful condition was noted. Prices showed this conclusively, 12s. again being touched for best steam. The latest quotations were: Best steam, 11s. 6d. to 12s.; seconds, 11s. to 11s. 3d.; best Monmouthshire, 10s. 6d. to 10s. 9d.; dry sorts, 10s. to 10s. 3d.; small, 5s. 6d. to 5s. 9d. f.o.b. Best house coal, 11s.; No. 3 Rhondda, 10s. 6d.; brush, 8s. 6d.; small, 6s. 6d.; No. 2 Rhondda, 8s. 9d.; through, 7s.; small, 4s. 6d.; patent fuel, 11s. to 11s. 6d.; coke, furnace, 15s. to 16s.; foundry, 17s. to 17s. 6d.; special, 20s. to 21s.

Cardiff Exchange iron and steel quotations for the week have been as follows:—Steel rails, heavy, £3 17s. 6d. to £4; light, £4 10s. to £4 15s.; Bessemer bar, £4 to £4 2s. 6d.: Siemens best, £4 5s. to £4 7s. 6d. Swansea Exchange quotations: Pig iron, Glasgow warrants, 43s. 8½d.; Middlesbrough No. 3, 36s. 5d. prompt; Middlesbrough hematite, 43s. 6d.; Welsh bars, £5 to £5 2s. 6d.; angles, &c., at usual extras f.o.t. at works; sheet iron, £6 to £6 10s.; steel sheets, £6 5s. to £6 10s.; steel bars, Bessemer, £4 to £4 2s. 6d.; Siemens, £4 2s. 6d. to £4 5s.; all delivered in district, cash less 2½; steel rails from £3 15s. to £3 17s. 6d. heavy; light, £4 10s. to £4 15s.; tin-plates, Bessemer's steel cokes, 10s. 6d. to 10s. 9d.; Siemens, 10s. 9d. to 11s.; ternes, 28 + 20, 20s. to 24s.; best charcoal, 12s. to 12s. 6d.; block tin, £71 5s. to £71 7s. 6d. Coke in steady demand at last prices. Pitwood generally improving.

I am glad to be able to report favourably of the South Rhondda colliery. The south crop of the Welsh coal basin has always been regarded as a doubtful area, and though a few have succeeded, the great mass of speculators have come to grief. One mining engineer of eminence described the great tract up towards Swansea as being like a battle ground, from the number of victims who had been sacrificed there. The South Rhondda is on the land of Mr. D. Owen, of Ash Hall, secured by him twelve years ago, and thanks to his knowledge and energy the development has been one of marked success. The yield of best No. 3 Rhondda is now 1000 tons a week, and on one occasion lately the output was 249 tons in one day.

One characteristic of the Welsh collier is extreme hardihood, and, in many cases, recklessness of a most censurable character, in which life is perilled without a thought. This week an Aberdare man, employed in the Treaman Colliery, was summoned for three offences against the special rules—(1) For firing a shot in the mine, (2) for having a match in his possession, and (3) for opening his lamp. The bench leniently let him off for £4 and costs. In consideration of the sacrifice of life which might have resulted, one would have thought that nothing but imprisonment and hard labour would have met the case.

Another step has been taken in the electric lighting of Monmouth. A majority of the Town Council voted at the meeting on Tuesday to appoint Mr. Lailey, C.E., Westminster, to prepare plans and specifications for the combined scheme for drainage and electric light in the borough. The whole of the work connected with the electric installation, as well as the conveyance of the sewage from the pumping station to the purifying tanks, is to be entrusted to Messrs. Bramwell and Harris.

Llanelly is progressing well, and taking its place as the fourth port of Wales. The harbour superintendent has reported successful boring operations carried out on the site of the present scouring reservoir, with the view of finding a good foundation for a new dock. During the half-year ended June 30th Llanelly exported 19,392 tons of tin-plates.

Those conversant with the coal history of Wales will hear with regret that Mr. John Nixon has resigned the post of chairman of the great colliery company of Nixon, Taylor, and Cory. Mr. Nixon remains simply as a shareholder, the retirement being due to his advanced age. He figured amongst the early pioneers of Wales. Locket, Marychurch, and Insole were the first shippers to London of Welsh coal, but John Nixon sent it farther afield, and is even cited as stoking a steamer on the Seine to show the value of the coal. He has rendered great services in the development of the Welsh coal trade, and in connection with the colliery working introduced the long wall system, and in the mechanical arrangements of his three large collieries carried out a perfect system which has been attended with safety from all but an occasional single accident. He is the inventor of the "ventilator," and it is claimed for him that during his career over six millions of men and boys have been up and down his pits without an accident. He was the first to experiment with steam coal in the locomotives of the Taff Vale Railway, in company with the late Mr. George Fisher. The general management of the collieries now devolves upon Major Bell.

There is a strike on at the Phœnix Dry Dock, Swansea. It is stated that the demands of the men for an increased wage are not justified by the state of trade.

I regret to announce the death of Mr. David Davies, principal of the Beaufort Tin-plate Works, Morriston, Swansea. Mr. Davies was a notable instance of industry. He began life as a farm labourer, and next filled a humble position at the Penydarran Works as a roll-cutter. One of the specialities of Penydarran was the nail rod, but at one of the Staffordshire ironworks a burnished one was turned out which was of a superior kind, and David Davies, on his own inspiration, travelled thither and worked in a humble capacity at the works until he learned the process, and, returning, he introduced this and made a fortune. He lived to acquire the ownership of the Penydarran estate, sold this, acquired the College Works, Llandaff, which he again sold, and finally bought the Beaufort Works, near Swansea, and was more successful than the generality in avoiding labour difficulties.

The Dean Forest colliers are agitating about deserting the sliding scale, and adopting the two years' arrangement on the Federated lines.

There are some rumours of discontent amongst the Welsh colliers, though of a slight nature. Federation agents predict that October will see the colliers giving in a notice to abandon the scale. This is, of course, the leading wish of the Federationists, but I question if it will be realised. D. Morgan, miners' agent, at a late meeting, stated that he would abide by the principle of the scale, and only advocate amendments, a statement received with applause.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

BUSINESS transactions on the iron market continue small, but the tendency of prices is tolerably firm. Export trade has been pretty lively, comparatively speaking. There is a specially good business done to Russia, and even the Dutch have come forward with some orders lately, which, though not very important, have been "thankfully received." On the Silesian iron market demand and sale are still exceedingly dull, and almost all the works complain of insufficient employment. This is particularly the case in the bar trade, where the scarcity of fresh orders is more keenly felt from week to week.

The Austro-Hungarian blast furnace works are satisfactorily engaged, chiefly on orders of previous date, and there is a pretty firm tone in prices to be noticed generally. With regard to the business in malleable iron there is not much activity reported in the different branches, orders for bars, plates, and girders coming to hand but slowly. There is, likewise, only a very poor inquiry experienced in the wire trade, while the various sorts of structural iron are in good call. The steel makers are rather badly off for new work just now. There are but very few contracts offering; the requirements for the Austrian State Railways are not likely to be given out this year, as was first intended, which has caused much disappointment. The same is the case with orders for locomotives and wagons, which will be divided over several years, so that prospects for the immediate future are not very favourable. The Rhenish-Westphalian works continue to throw their over production on the Austro-Hungarian market, and have been rather successful of late, especially in Bohemia, where pretty large lots have been sold. The present official quotations are: For common forge pig, 42·50fl.; grey ditto, 48fl.: mixed lots, 43fl. to 45fl.; Bessemer, 48fl. to 50fl., free Vienna; Bessemer ingots, 75fl. to 80fl., free Vienna. Styrian bars, 107 50fl. to 115fl.; girders, 106fl. to 110fl.; heavy plates, 180fl.; tank ditto, 135fl.; sheets, 145fl., all per ton.

On the French iron market business all through continues very quiet, but there is still a regular activity maintained at the works, and makers appear less inclined to go down with their quotations now than in previous months. The articles at present most neglected are plates, for which an exceedingly poor inquiry is coming forward. Much the same is the case with hardware. French business in coal during the first two quarters of present year was as under:—

Import
from Jan. 1st to June 30th.

| Coal from | 1894. t. | 1893. t. | 1892. t. |
|---|---|---|---|
| England | 2,141 520 | 1,993,495 | 2,026,336 |

Belgian iron trade does not show much change on the week. Prices for pig iron, especially those for forge pig, show a somewhat weaker tone of late, although inland demand for most sorts of iron and steel has experienced a slight improvement, while export business is as dull as ever. Import of iron in June of present year amounted to 36,898 t., against 15,321 t. for the same period the year before, and against 25,653 t. in 1892. During the first two quarters of 1894 total import of iron was 119,684 t., in the year before it was 58,309 t., and in 1892 it amounted to 68,779 t. Belgian trade in artificial coal—briquettes—has very much improved during the last two years, large quantities being sent to England, Italy, Sweden and Norway, Switzerland, Spain, Egypt, Algiers, Luxemburg, and the United States. Export in artificial coal during the first five months of the year shows an increase of 65,000 t. against the previous year, and 134,000 t. against the corresponding period in 1892. During the first two quarters of the present year 307,919 t. of artificial coal were exported from Belgium, against 230,543 t. for the corresponding period last year. Of these, 2650 t. were sent to Algiers; 9867 t. to Germany, 7805 t. to England, 1150 t. to Columbia, 345 t. to the Congo, 9540 t. to Egypt, 9015 t. to Spain, 34,600 t. to the United States, 114,879 t. to France, 16,440 t. to Luxemburg, 7040 t. to Italy, 6906 t. to the Low Countries, 1550 t. to Russia, 10 t. to Sweden and Norway, 47,436 t. to Switzerland, 1970 t. to Turkey, and 40,316 t. to other countries.

On the whole, the Rhenish-Westphalian iron business remains without improvement; here and there a slightly better tone has been reported; but, taking it all through, the condition of both the crude and the finished ironworks is quite as unfavourable as before, and it is rather astonishing that prices, at least those for raw iron, have been pretty well maintained up to the present. The malleable iron trade is rather slack; very few orders come to market both from inland and abroad, and negotiations remain weak. Girders are in quiet request. The prices for hoops are excessively low just now, owing to insufficient employment of the mills, and there is much the same to be reported of plates and sheets, quotations being now at figures which leave no margin of profit. Drawn wire has been tolerably well inquired for on foreign account lately, while inland demand remains extremely dull. Foundries and machine shops continue in a poor condition, generally, while the wagon shops are reported in regular employment, which is likely to continue for some time ahead.

## AMERICAN NOTES.

NEW YORK, Sept. 5th, 1894.

THE condition of affairs in this country can be best understood by reference to railway earnings for last year. The decrease for first half 1894 in gross earnings was 16½ per cent. on 234 roads, representing 153,355,000 of capital. The estimate of the total gross loss on all roads for the six months is 100,000,000 dols. The decrease in manufacturing is estimated at 20 to 25 per cent. Farm products have declined in value. Building enterprise has been checked. At the same time there is much work in prospect, from railroad building down to house building. The tariff settlement has made no change, and there will be no improvement until after the November elections, when there will be an overwhelming Protectionist victory that will frighten the revenue reformers. Iron and steel quotations are unchanged. Bessemer pig production is increasing. The steel rail mills are booking large orders for delivery in October and November.

## LAUNCHES AND TRIAL TRIPS.

The s.s. South Gwalia is a vessel built by Messrs. Wm. Gray and Co. to the order of Messrs. Evan Jones and Co., and engined at the Central Marine Engine Works. Her dimensions are:—Length over all, 282ft.; breadth, 38ft.; depth, 20ft. 8in. Her engines have cylinders 20in., 31½in., and 53in. in diameter, with a piston stroke of 36in. The boilers are of extra large size, working at 160 lb. per square inch. Having adjusted the compasses, the engines were run full speed ahead for about a couple of hours, and although the very stormy state of the weather caused a great deal of racing, the engines ran in a perfectly satisfactory manner in every respect, and as soon as the trial was over she proceeded on her voyage to London to load. The vessel has been built under the personal supervision of Captain Jones, and the building of her engines has been superintended by Messrs. J. C. Hallett and Co., of Cardiff, whose inspector, Mr. Patterson, accompanied the ship to London.

On the 30th August Messrs. Rickmers and Co. launched from their yard at Bremerhaven the coasting tank steamer Sabine Rickmers, constructed specially for the carriage of petroleum in bulk, and built under the superintendence of Messrs. Flannery, Baggallay, and Johnson, of London and Liverpool. The vessel is 200ft. long, 30ft. 6in. beam, and 20ft. 9in. moulded depth. Her engines are of the direct-acting triple-expansion type, with cylinders 17⅜in. by 28in. by 44½in., with a stroke of 37⅜in., and are supplied by steam at 160 lb. pressure by a circular multitubular boiler 14ft. 6in. extreme diameter, 10ft. 6in. long, fitted with three Purves patent ribbed furnaces, 3ft. 6in. diameter, and about 7ft. long. The oil is carried in three tanks amply stiffened to Bureau-Veritas Surveyor's approval, so that any one tank may be full while others are empty. Ample ventilation is fitted in bunkers and in cargo tanks. Hand-steering gear is fitted amidships to work on pilot bridge. A large donkey boiler capable of making a good head of steam when both cargo pumps are being fully worked is being fitted.

On Monday the s.s. Cierbana left the Cleveland dockyard of Sir Raylton Dixon and Co., Middlesbrough, for her official trial trip, which was very satisfactory. She is a steel screw steamer of the raised quarter deck type, and has been built to the order of Senor Ramon de la Sola, of Bilbao, and takes Lloyd's highest class. The principal dimensions are:—Length, 234ft.; beam, 34ft.; depth moulded, 17ft. 6½in., with a carrying capacity of about 1900 tons at a light draught of water. A very complete outfit of deck machinery is provided for loading and discharging cargoes, working anchors, &c. The decks and deck erections are all of steel and iron, and water ballast will be carried in the cellular double bottom, which extends right fore and aft, and the after peak is also fitted as a ballast tank. The engines are by the North-Eastern Marine Engineering Company, of Sunderland, the cylinders being 16in., 26in., and 43in. by 30in., with one large boiler working at 160 lb. pressure. The construction of the vessel has been carried out under the supervision of Captain Ybarra, and the vessel will be employed in the ore trade between Bilbao and Middlesbrough.

The Lady Gray is the latest addition to the fleet of Messrs. John Coverdale and Son, of West Hartlepool. and has been built by Messrs. Wm. Gray and Co., and engined at the Central Marine Engine Works. She is a vessel taking Lloyd's highest class, and her dimensions are: Length over all, 310ft.; breadth, 40ft.; and depth, 20ft. 10in. Her engines are of the triple-expansion type, having cylinders 22in., 35in., and 59in. diameter, with a piston stroke of 39in. Steam is supplied by two large single-ended boilers working at 160 lb. pressure. The trial trip was made off Hartlepool, the compasses having been adjusted in dock owing to the bad state of the weather. The engines were run full speed for about a couple of hours, everything running perfectly satisfactorily, there being no hitch or trouble of any kind. The Lady Gray is fitted in her engine-room with all the latest improvements developed at the Central Engine Works, including the Mudd and Airey patent metallic packing in all the piston-rods and spindles, which on the trial trip ran perfectly steam-tight and satisfactorily in every respect. Several shareholders and others interested were on board the vessel, including the managing owner, Mr. Robt. Coverdale, Mr. Airey, superintending engineer, Dr. Rawlings, Mr. J. T. Kay, Rev. E. R. Ormesby, Mr. Sanderson, Mr. G. H. Baines, Mr. Geo. Jones and Mr. T. Mudd. Immediately after the trial, the vessel proceeded on her voyage to Cardiff to load for the Mediterranean.

On Thursday morning, the 6th inst., the s.s. Maristow left the Cleveland dockyard of Sir Raylton Dixon and Co., Middlesbrough, for the purpose of testing the machinery and general working of the steamer at sea. She is a steel screw steamer of the partial awning deck type, and takes Lloyd's highest class. This vessel has been built to the order of Messrs. Bellamy and Co., of Plymouth, and is the fourth steamer constructed by these builders for the same owners. She is intended to replace a vessel of similar name which they sold a short time since. The principal dimensions are:—Length, 298ft.; beam, 40ft.; depth moulded, 21ft. 2½in.; and she has a deadweight carrying capacity of over 3600 tons. Shifting boards are fitted throughout for the carrying of grain cargoes. The awning and quarter decks are of iron, the main deck of steel, and the vessel is sub-divided transversely by six water-tight bulkheads. She is rigged as a fore-and-aft schooner, with pole masts of steel, which are fitted with Sidgwick's patent hinge arrangement, by means of which the topmasts can be immediately lowered when the vessel is required to pass under such obstacles to navigation as the permanent bridges on the Manchester Ship Canal, &c. The engines are by Messrs. T. Richardson and Sons, of Hartlepool, the cylinders being 22in., 35in., 59in. by 39in., and steam is supplied by two large steel boilers working at 160 lb. pressure per square inch. The building of the steamer has been under the superintendence of Mr. George Walker, naval architect, of London. The trials were most satisfactory in every sense.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

⁂ When patents have been "communicated" the name and address of the communicating party are printed in italics.

*20th August*, 1894.

16,487. Hair Comb Binder, P. Shields, Belfast.

16 488. Knitting Machines, J. A. A. Claringburn and A. Banks, Nottingham.

16,489. Blouse or Dress Fastener, H. Munslow, London.

16,490. Rims or Fellows for Wheels, W. Bowden, Manchester.

16,491. Gas Lights, T. Barker, Manchester.

16,492. Wired-on Pneumatic Tires, J. Harrison, Birmingham.

16,493. Looms for Weaving, E. Westwell and J. Mitchell, Halifax.

16,494. Wire-covered Steam Pipes, D. B. Morison, Hartlepool.

16,495. End-warp Leasing Machine, J. Law, Rochdale.

16,496. Handle for Billiard Cue Rest, T. Ritchie, Loughborough.

16,497. Barrels for Containing Liquor, A. E. Allison, Newcastle on-Tyne.

16,498. Motor Engines, J. Southall, Worcester.

16,499. Cuff or Sleeve Links, J. Hopewell, Manchester.

16,500. Securing Glass in Frames, C. Jost, Bradford.

16,501. Attaching Belts to Buckles, M. Winkfield.

16,502. Trace Chains for Horses, D. N. McKelvie, Glasgow.

16,503. Holding Book Rests in Position, B. R. Walker and H. Woodward, Birmingham.

16,504. Cycle Lamps, H. Aulton and R. Merchant, Birmingham.

16,505. Vehicles, A. Fehlen and The Princess Company, Ld , London.

16,506. Coupling Wrench, G. Sheepway and J. Smith, Gloucester.

16,507. Fixing Door Handles on to their Spindles, R. Frame, Glasgow.

16,508. Sign Plates, W. S. Brown and R. Lugton, Glasgow.

16,509. Marine Boiler, L. M. Brayne. Glasgow.

16,510. Fastening Boot Laces, S J. Heinig, London.

16,511. Chair Seat Supporter, T Palmer, Burnley.

16,512. Umbrella Frames, J. P. O'Donnell.—(*F. Giles, Australia*)

16,513. Repair of Pneumatic Tires, C. T. Austen, London.

16,514. Skates, N. Browne.—(*H. Wirths and Sohn, Germany.*)

15,515. Disinfecting Sewer Gulleys, M. and J. Miller. London.

16,516. Meters for Measuring Fluids, J. G. Galley, London.

16,517. Type writing Machines, R. Toepper, London.

16,518. Supports to Hold Stands, N. A. Aubertin, London.

16,519. Pocket for Ladies Dresses, E. Grahame and J. Eddels, London.

16,520. Driving Gear of Velocipedes, F. Russell, London.

16,521. Axle Boxes for Railway Carriages, H. Rees and T. Hulme, London.

16 522. Spring Wheels for Cycles, D. Smith, jun., London.

16 523. Tapes for Curtains, &c, A. E. Fryant, London.

16,524. Tube Pincers, W. Bürkle, Germany.

16,525. Adjustable Garment, C. Thill and H. Puhlmann, Germany.

16.526. Protecting Cases for Matches, H. Klein, Germany.

16,527. Appliances for Sewing Machines, A Bucholz, Germany.

16,528. Cigar and Cigarette Holder, J. Nadler, London.

16,529. Making Potassium Cyanide, G. Kraemer, London.

16,530. Colouring Matters, C. D. Abel.—(*The Actien Gesellschaft fur Anilin Fabrikation, Germany*)

16,531. Steam Heating Apparatus, G. L. Berry, London.

16,532. Electric Lamps, W. E. Conze.—(*F. W. Busch, Germany*)

16,533. Heating Water, J. E. Joselin and J. H. Stevens, London.

16.534. Heating Apparatus, M. A. L. Siffert, London.

16,535. Tea Strainer, G. F. Pierce and F. W. Warrick, London.

16,536. Transporting Corrosive Acids, R. England, London.

16 537. Attaching Pneumatic Tires, P. W. Tillinghast, London.

16,538. Safety Pins, K. E. Winge, London.

16,539. Vessels, C. S. Snell, Saltash.

16,540. Firing Mines Electrically, C. A. Terrey, London.

16,541. Manufacture of Wood Wool, J. M. Webster, London.

16,542. Search-light Projectors, J. B. Furneaux and H. Walker, London.

16,543. Picture Toys, &c., F. Mitchell, Surrey.

16,544. Supporting Persons when Cleaning Windows, H. C. Stanze, London.

16,545. Valve Steam Engines, N. J. Poulsen, London.

16,546. Navigable Vessels, R. Harte, London.

16,547. Propelling Machinery, &c , by Pressure, S. Appleby, Middlesbrough.

16,548. Producing Substitutes for Coffee, R. Haddan.—(*Kathreiner's Malzkaffeefabriken mit beschränkter Haftung, Germany.*)

16.549. Stoneworkers' Gauge Squares, J. H. Gorman, London.

16,550. Match-boxes, &c , C. E. Campbell, London.

16,551. Ferrule for Umbrellas, &c., J. Hurlock and S. Hurlock, London.

16,552. Bunkering or Coaling Steamships, J. Dixon, London.

16,553. Ladies' and Children's Dresses, H. A. Dale, London.

16,554. Nailing Machines, H. Hyde.—(*F. D. Locke, United States*)

16,555. Bicycles, &c., T. Hall and J. Davies, Manchester.

16,556. Fancy or Business Postcards, C. Schell, Liverpool.

16,557. Metal Ingots, W. P. Thompson.—(*Stumm Bros., Germany*)

16,558. Agitating Apparatus for Ice-making Tanks, J. Price, Liverpool.

16,559. Acid Manufacture, G. W. Johnson.—(*Kalle and Co., Germany.*)

16,560. Driving Gear for Tricycles, W. P. Beaver, London.

16,561. Constructing Name-plates, &c., J. B. Adams, London.

15,562. Forming Sheet-metal Boxes, S. B. Stevens, London.

16,563. Firewood Splitting Machines, A. P. Blaxter, sen., and S. O. Holmes, London.

16,564. Sash Fasteners for Sliding Doors, E. Clare, London.

16,565. Postal Wrapper, S. H. Crocker, London.

*31st August*, 1894.

16,566. Safety Air Valve for Cycles, G. Wright, Nottingham.

16,567. Gravitation Motor, J. H. Fitzgerald, Belfast.

16,568. Pleasure Boat, M. Bagnall, Wolverhampton.

16,569. Automatic Delivery Match-box, F. J. Commin, Exeter.

16,570. Adjustable Rack Spanner, E. Barnes, Birmingham.

16,571. Decorative Plates, M. Kohl and E. Kuppert, Manchester.

16,572. Spinning Tops, S. Barnes, Middleton.

16,573. Pneumatic Tires, H. Kesterton, Manchester.

16,574. Furnace and Flue Tubes, E. C. Mills, Manchester.

16,575. Stove, W. Feyton, Halifax.

16,576. Texture Grip, J. A. Riley and E. Tyrrell, London.

16,577. Raising, &c , of Window Sashes, T. Robb, Glasgow.

16,578. Pickers for Over-pick Looms, H. Cruse, Manchester.

16 579. Bobbin Frames, C. Clay and H., T., and J. J. Burgess, Congleton

16,580. Latches, W. H. Wathen. Birmingham.

16,581. Roofing Tiles, H. E. Hayes. Bristol.

16,582. Making Cardboard Boxes, W. Crosland, Manchester.

16,583. Boring Machines, G. S. Waterfall and C. H. Woods, Sheffield.

16,584. Construction of Cycle Handles, J. Brailsford, Sheffield.

16,585. Set-square and Ruler, J. J. Hughes, Carmarthen.

16,586. Photographic Mounts, F. W. Hayward, Norwich.

16,587. Line-throwing Apparatus, J. Griffiths, Swansea.

16,588. Pipe, W. Jones, Cardiganshire.

16,589. Loom Shuttles, H. Cruse, Manchester.

16.590. Pockets for Ladies' Dresses, A. M. Turner, London.

16,591. Deckplate, H. B. and J. S. Watson and M. C. James, Newcastle-on-Tyne.

16,592. Pneumatic Butt End for Guns, W. W. Tonks, Birmingham.

16,593. Heating Dwelling Houses, &c , A. Bruce, Glasgow.

16 594. Cycle Pedals, M. Carswell, jun., Glasgow.

16,595. Compensation Gear, A. E. Beck and W. E. Preston, Birmingham.

16,596. Roving Frame Construction, J. Arrowsmith, London.

16,597. Oil and Gas Heating Apparatus, F. H. Rosher, Kent.

16,598. Vehicle Wheels, J. Bonn, London.

16,599. Regulating Electric Currents, L. B. Miller, London.

16,600. Cycles, T. J. Whiteman, London.

16,601. Holder for Canned Meats, &c., R. F. Mosley, London.

16,602. Gate Spring, C. W. N. Worssam, London.

16,603. Attaching Trade-mark Labels to Frames of Umbrellas, W. A. Bindley, W. J. Gell, and A. F. Boham, London.

16,604. Apparatus for Boring Earth, F. M. McLarty, London.

16,605. Street Sprinkler, H. C. Pollman, London.

16,606. Carbons for Electric Arc Lights, H. C. Barker, jun., London.

16 607. Spring-linked Chain, J. D. Derry, London.

16,608. Plectrums for Mandolines, &c., W. E. Blaker, London.

16,609. Support for Bicycles, C. Pécasse, London.

16,610. Boxes, G. T. Tournier. London.

16,611. Treatment of Fancy Leather, S. H. Epstein, London.

16 612 Manufacture of Paper, P. C. Peebles, London.

16,613. Lamp Glasses, C Quitmann.—(*The Aktien Gesellschaft für Glasindustrie vormals Friedrich Siemens, Germany*)

16,614. Wheel Bearings and Axles, E. Germaine, London.

16,615. Rifle Rest, F. J. Nelson, London.

16,616. Envelope Openers, G. L. Lavington and E. A. Wright, London.

16 617. Clips for Cyclists, A. J. Boult.—(*S. C. Peuchen and P. Clarke, Canada*)

16,618. Motors, A. D. Torre, London.

16,619. Fare-registers, A. J. Boult.—(*A Pfoff, United States.*)

16,620. Valves for Exhaust Pumps, J. W. D. V. Galwey and R. J. Eskrigge, Liverpool.

16,621. Mask Respirator, F. Détourbe, Liverpool.

16 622. Curtains, Pratt, Hurst, and Co., Ld., and T. B. Walker, London.

16,623. Attaching Trade-marks, W. Corder and F. J. Turley, jun., London

16,624. Apparatus for Making Hats, J. Cass, London.

16,625. Process for Engraving Photographs, T. Reich, London.

16,626. Extracting Nibs from Penholders, J. R. Rixen, London.

16,627. Mud-guards for Cycles, H. E. Earl, London.

16 628. Device for Scraping Salt, J. R. Rixen, London.

16,629. Letter Cards, J. Price, London.

16,630. Apparatus for Receiving Coins, E. Edwards.—(*A. Böchsmann, Austria.*)

16,631. Cutter Bars, A. Taylor, London.

16,632. Holder for Hats, W. J. Pendleton, London.

16,633. Tobacco Pipes, W. Shelley, London.

16 634. Calipers, J. Y. Johnson.—(*The Eagle Pencil Company, United States*)

*1st September*, 1894.

16,635. Reducing Vibration in Vehicles, S. H. Stubbs, Manchester.

16,636. Automatic Bicycle, C. Watkin and J. Pickup, Liverpool.

16,637. Socket Castor, J Edwards, London.

16,638. Bottles, J. W. Kilner, Leeds.

16 639. Fire-grate Niggar, E. W. Banner, Southport.

16 640. Rain-guard for Velocipedes, T. Cole, Bournemouth.

16 641. Forks, V. B. Thompson, Sheffield.

16 642. Boiler Furnaces, T. Heppell and R. Auton, Newcastle on-Tyne.

16,643. Match-boxes, J. B. Howard.—(*J. Trendal, Germany.*)

16,644. Dishes, J. Hughes and G. M. Billington, Longport.

16.645. Wheels for Velocipedes, Count C. de Rossetti, London.

16,646. Window Sash Fasteners, S. Daw, Southampton.

16,647. Belt Fasteners, I. Jackson, Manchester.

16,648. Scutching Machines, J. Foulkes, J. E. Park, and G N. Peake, London.

16,649. Clip for Stentering Machines, J. Bridge, Accrington.

16,650. Apparatus for Drying Damp Substances, W. H. Bowers, Manchester.

16,651. Brick-pressing Machines, T. C. Fawcett, Halifax.

16,652. Watchman's Tell-tale Clock, F. Brook, Huddersfield.

16,653. Advertising Sign, D. F. Adamson, F. W. Atterbury, and A. H. Hyslop, London.

16,654. Concrete Structures, J. Sheppard and F. Dashwood, London.

16,655. Machines for Pressing Straw, J. E. S. Perkins, Peterborough.

16,656. Music Stands, J. Jackson, Coventry.

16,657. Rough for Horseshoes, J. Bill, Stourbridge.

16,658. Evaporation Apparatus, &c., J. T. Bottomley, Glasgow.

16,659. Screw Bolts, J. Rankin, E. Beckitt, and J. K White, Glasgow.

16.660. Railway Buffer and Draw Gear, I. A. Timmis, London.

16,661. Covers for Periodicals, C. D. Long, Sheffield.

16,662. Furnaces, G. Clark, Sheffield.

16,663. Hay-cutting Knife, C. Garfitt.—(*The James Russell Barrett Company, United States.*)

16,664. Treating Bully-tree Gum, R. Hutchison, Glasgow.

16,665. Ventilating Casks, A. E. Jolley and J. L. Browning, London.

16,666. Method of Stringing Beads, A. E. Edwards, Manchester.
